En Argentina los glaciares y otras crioformas cumplen un papel trascendente en el desarrollo regional y son componentes emblemáticos del patrimonio ambiental de la Cordillera de los Andes. Entre otros atributos, estos cuerpos de hielo son reconocidos como componentes cruciales del sistema hidrológico de montaña y como "reservas estratégicas" de agua para las zonas bajas adyacentes en gran parte de la diagonal árida del país.

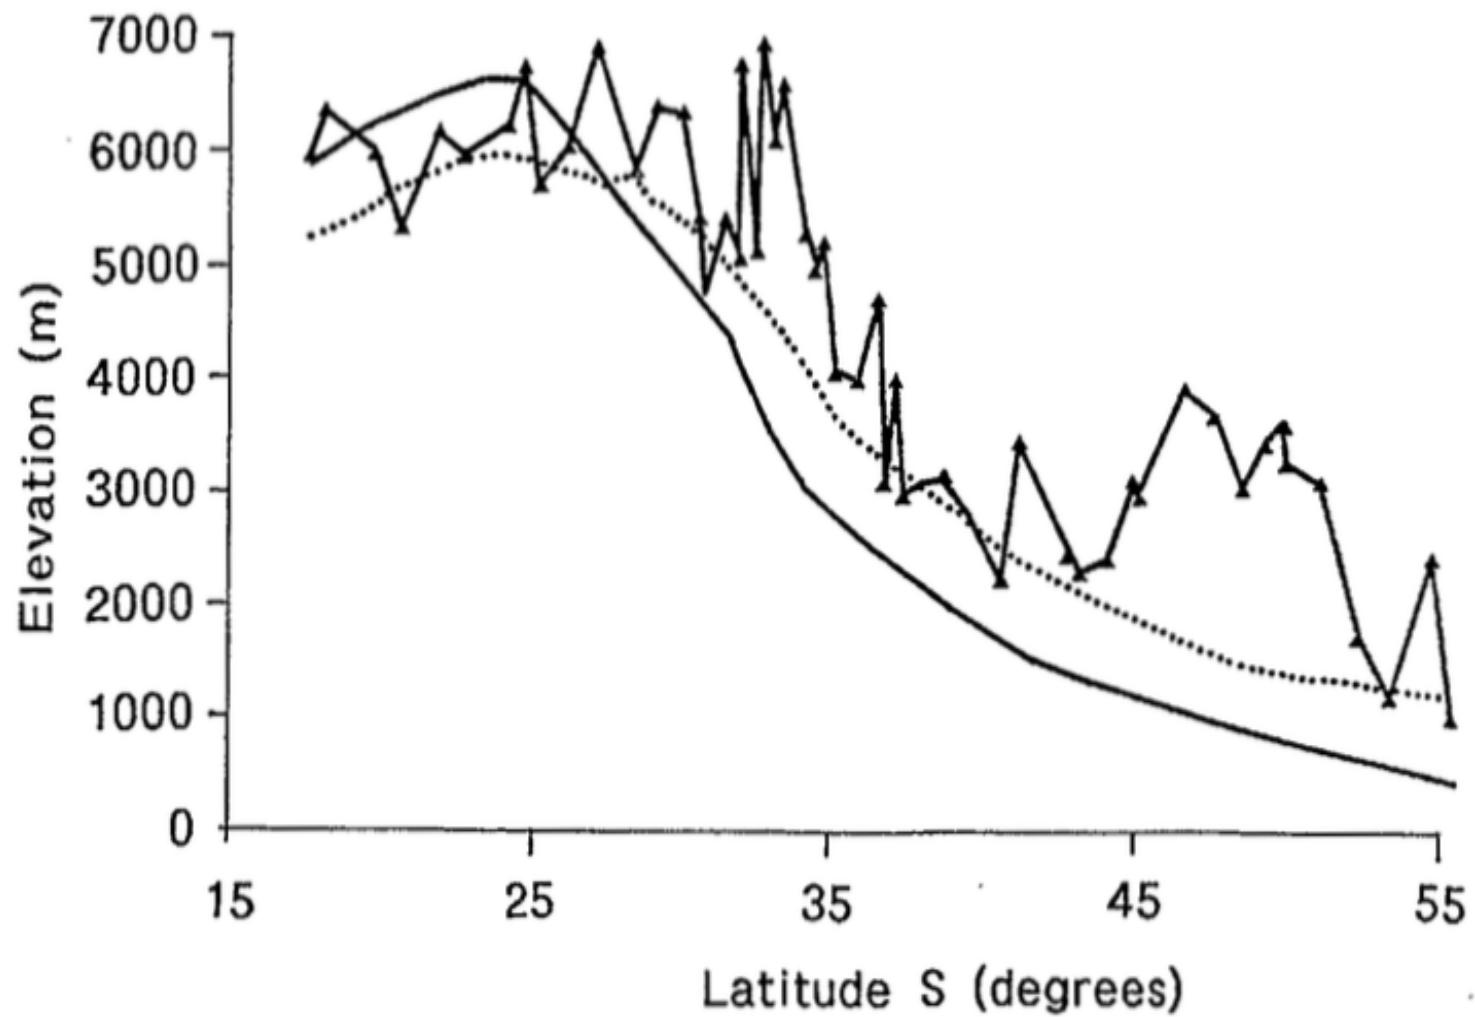

Si bien la nieve que se acumula cada invierno en la Cordillera constituye la principal fuente de agua para

Ferri, L. 2015. The glacier inventory of the Central Andes of Argentina (31° -35° S). AGU Fall Meeting, San Francisco, Abstract ID 73876.

8069 glaciers covering an area of 1768 km².

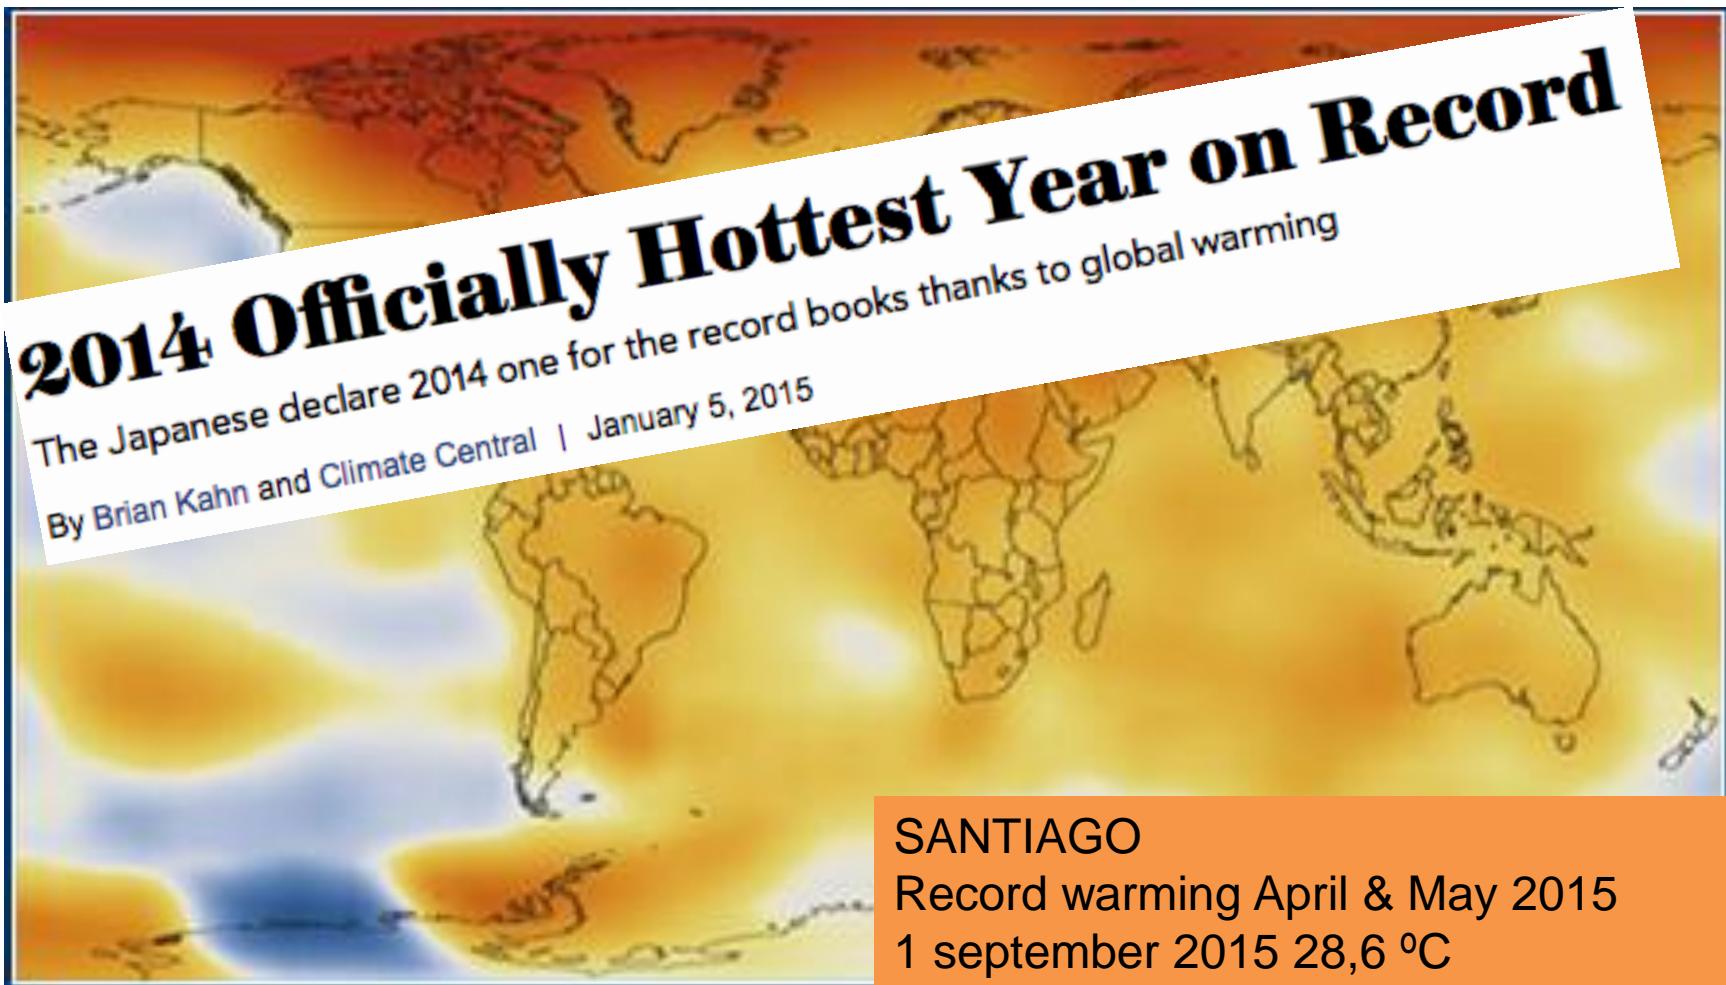

Debris-covered ice and rock glaciers represent 57% of the total inventoried area.

Gradual transition from debris-covered glaciers, in the upper part, to rock glaciers, in the lower sector.

Latitudinal variation of the approximate equilibrium line altitudes (ELAs) on the western (continuous line) and on the eastern Andes (dotted line), together with the highest elevation of peaks (line with triangles). The ELAs are adapted from the regional snowlines of Nogami (1972). (From Casassa et al., 1998)

Mass loss and imbalance of glaciers along the Andes Cordillera to the sub-Antarctic islands

GPC, 2015

Sebastian H. Mernild ^{a,*}, Andrew P. Beckerman ^b, Jacob C. Yde ^c, Edward Hanna ^d, Jeppe K. Malmros ^{e,f},
Ryan Wilson ^a, Micheal Zemp ^g

Empirical Orthogonal Function analysis

Mean annual observed mass-balance B changed from -620 ± 390 (1993–2002) to $-740 \pm 240 \text{ kg m}^{-2} \text{ yr}^{-1}$ (2003–2012) and for this past decade showed a decrease in B from south to north.

These glaciers had a mean accumulation area ratio of 0.42, which is below the AAR value for glaciers in equilibrium, reflecting mean area and volume imbalances of 23% and 27%, respectively.

Glaciers in the northern part of Andes Cordillera are most out of balance with the present climate (33%), while glaciers on the sub-Antarctic islands are only slightly out of balance (4%).

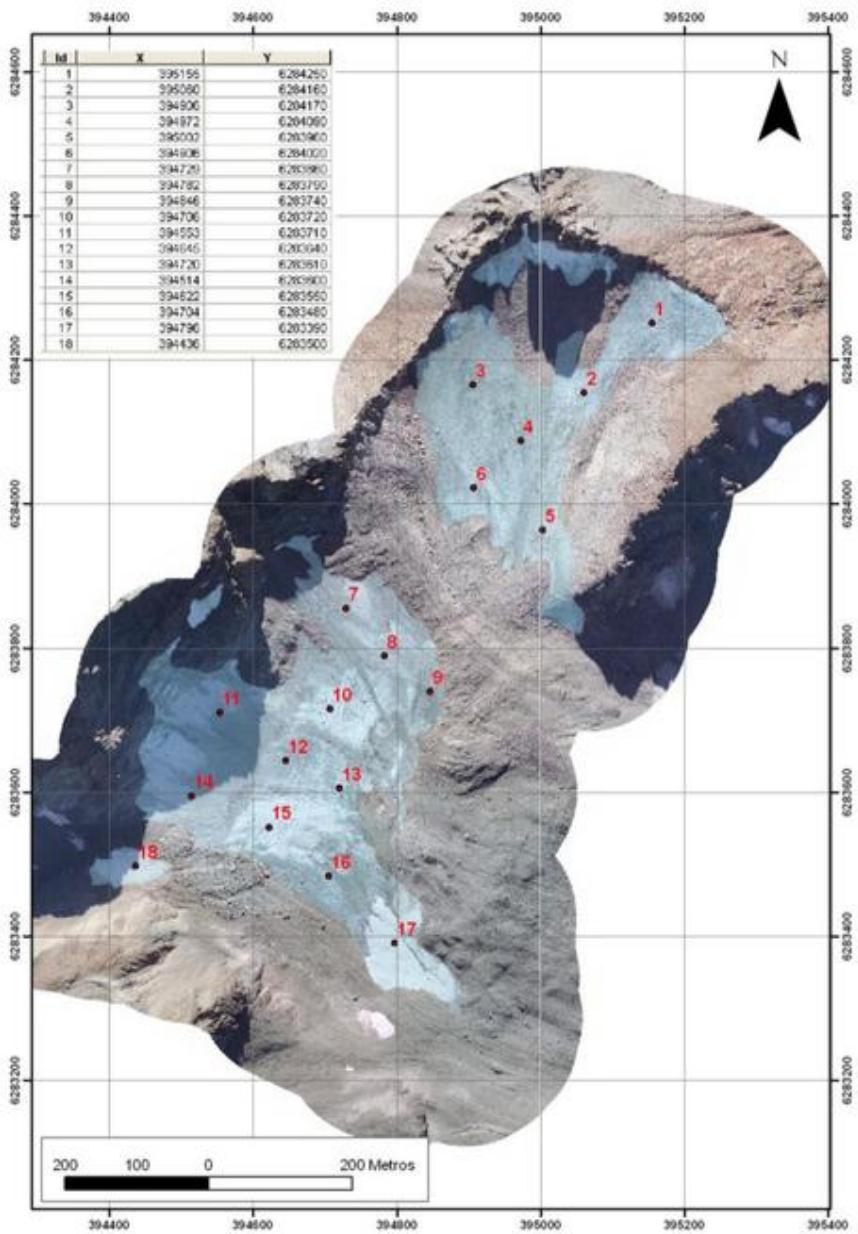

Spatiotemporal cycle of B distinguishes glaciers on the sub-Antarctic islands from glaciers in the Andes. South America should be divided into three individual glacier regions, and not two regions as earlier stated.

Melt of the “deglaciation discharge dividend” (Collins, 2008) until a maximum peak level is attained, subsequently decreasing when the glacier is not able to sustain such large melt water production due to its reduced size, until finally the discharge drops to the base flow level when glacier extinction is reached.

Hypothetical shift from a glacio-nival regime to a more nivo-pluvial regime at Maipo River at El Manzano station (850 m asl), central Chile, as a response to a future warming scenario under constant annual precipitation, which is consistent with model predictions (e.g. Serrano, 2014).

Reconsidering the glacier to rock glacier transformation problem: New insights from the central Andes of Chile

Sébastien Monnier ^{a,*}, Christophe Kinnard ^b

Geomorphology 238 (2015) 47–55

CONCLUSIONES

El aumento de temperatura en el último siglo, principalmente causado por el efecto invernadero, ha resultado en una reducción de la criosfera a nivel global, incluyendo los glaciares de los Andes del Sur.

Sequía en Chile centro-norte en los últimos años.

A mediano-largo plazo el rol de los glaciares y la nieve en el balance hídrico será cada vez menor.

Ante la dificultad de mitigar (reducción de gases de efecto invernadero, control de la contaminación (efecto albedo), uso de fuentes de energía renovables), no queda más de ADAPTARSE a un planeta más cálido.

Legislar (en Chile) e implementar de manera óptima el sistema de EIA en Chile y Argentina respecto de la criosfera.

Necesidad de estudios más detallados!
