# PREFACE

*Koïchiro Matsuura*
*Director-General of UNESCO*

With the publication of this seventh and final volume of the *History of Humanity*, UNESCO has successfully completed one of its earliest and most ambitious projects: the publication of a universal work of international cooperation conceived to provide 'a wider understanding of the scientific and cultural aspects of the history of mankind and of the mutual interdependence of peoples and cultures and their contributions to the common heritage' (Resolution 5.7 of the UNESCO General Conference at its second session, November 1947).

It is worth emphasizing that this noble objective lies at the very heart of UNESCO's founding principles of 'advancing the mutual knowledge and understanding of peoples' and 'promoting the free flow of ideas and images' as stated in the Organization's Constitution.

The task of 'composing a universal history of the human mind from the varying stand-points of memory and thought that characterize the different contemporary cultures' was, indeed, a challenge for UNESCO. In the late 1960s – some twenty years after launching this prodigious editorial project – the First International Commission, in collaboration with a distinguished team of scholars from different countries and backgrounds, gave birth to the six-volume *History of the Scientific and Cultural Development of Mankind*. This work, which eventually appeared in six languages, received wide praise for the high quality of its contributions and the originality of its approach.

However, it is common knowledge that all historiography is 'work in progress' and, in the continuous flux of history, neither interpretations nor facts are set in stone. In fact, history itself has moved on, altering in the process the perspectives from which the past is viewed. It is therefore hardly surprising that, shortly after the completion of the first edition, both compilers and readers became aware of the need for extensive revision owing to a number of factors, particularly the astonishing advance of knowledge and achievements since the project's inception, but also the increasing demand for pluralism in historical approaches.

Moreover, many considered that this first edition still reflected, to a certain degree, the predominant Eurocentric vision characteristic of the period and that certain regions and countries, especially those that had achieved independence since the end of the Second World War, were not adequately represented.

In 1969, the President of the International Scientific Commission, the late Paulo E. de Berrêdo Carneiro, prophetically declared: 'The day will come when that which we have written ... will have to be replaced. I should like to think that our successors will attend to this, and that a revised version of these volumes may be published at the dawn of a new millennium'.

And just a decade later, that day came. In 1980, the Commission recommended to the General Conference that the new *History of the Scientific and Cultural Development of Mankind* should not be merely a revision, but rather a radical revamping of its predecessor. Thus, the new edition – later renamed the *History of the Scientific and Cultural Development of Humanity* and commonly referred to as the *History of Humanity* – would reflect new developments in historical methodology and recent findings of historical research in all fields of study (especially emerging disciplines), while presenting a broad and balanced picture of the different world cultures without imposing any one philosophy of history or proposing any particular civilization or period as a paradigm.

With a view to responding to the demand for a decentralization of historical viewpoints and interpretations and complementing the *History of Humanity* collection, UNESCO also decided to undertake a series of regional histories reflecting the perspective of the populations concerned and published in several languages to reach the widest possible readership. Among the series are the six-volume *General History of the Caribbean*, the six-volume *History of the Civilizations of Central Asia*, and the *General History of Africa*, comprising eight volumes and also published in several African languages including Hausa, Kiswahili and Fulani. The completion of the latter series in 1999 saw the commencement of a second phase intended to extend the dissemination of this work to the greatest number of readers and particularly Africans. Meanwhile, the international editorial teams continue their work on the two other regional histories: the *General History of Latin America* (eight of the nine volumes have been published to

date) and *The Different Aspects of Islamic Culture* (three of the six volumes have been published so far).

This new approach to presenting the history of the development of humankind is consistent with UNESCO's ongoing commitment to enhancing awareness of cultural diversity and promoting pluralism in cultural exchanges. These ambitious goals have become even more urgent in light of the dizzying pace of globalization in recent times. As reaffirmed by UNESCO's Universal Declaration on Cultural Diversity, adopted by its General Conference in 2001, 'cultural diversity is an ethical imperative inseparable from respect for human dignity'.

The construction of true cultural pluralism first requires the abandonment of prejudices and the rise of a shared culture based on the acceptance of diversity. I am confident that the *History of Humanity* will contribute towards the realization of these noble objectives by fostering intercultural understanding and reinforcing the central notion of unity within the diversity of the human family and the interconnectedness of progress and development in all parts of the world.

Today, more than 25 years after the decision to create a new *History of Humanity*, I am very proud to present this completed second edition, which has greatly expanded upon the pioneering work of those dedicated scholars responsible for the first edition. I should like in particular to express my admiration of and deep gratitude to the members of the Second International Commission and to the 540 distinguished specialists from all geocultural backgrounds working in some 85 countries who have contributed to this historic undertaking. A project of this magnitude and complexity inevitably encounters its share of hurdles in the form of delays, painstaking revisions, etc. However, the intellectual integrity and unwavering dedication and patience of all those involved in this extraordinary exercise in international and intercultural collaboration have enabled us to weather the storm and achieve our objective.

I am sure that readers will make known their own views in the years to come. Of course, the Commission is well aware that given the time it took to complete the project and the ever-increasing pace of scientific research, the present edition might fail to take into account some of the latest findings in certain fields. Such shortcomings are inevitable.

Nevertheless, in committing this work to their scrutiny, UNESCO and the International Commission are taking the final step in the task entrusted to them by the community of Member States represented at the General Conference. It is my firm belief that each of us stands to benefit from this great testimony to our common past and act of faith in our shared future.

# CONTENTS

# FOREWORD

*Charles Morazé*
*former President of the International Commission*

Among the great tasks assigned to UNESCO by the Constitution is the duty to promote and encourage mutual knowledge and understanding throughout the world. While many of the divergences that divide people date from a distant past, an analysis of their historical antecedents discloses links which draw them nearer to one another, brings light to their contributions to a common patrimony of humanity, reveals the ebb and flow of cultural exchanges and emphasizes their increasing tendency to become integrated into an international community.

So wrote Paulo E. de Berrêdo Carneiro, president of the International Commission (1952–69) in the opening paragraph of the preface to the *History of the Scientific and Cultural Development of Mankind* in 1963. Today, it would be difficult to say anything about humanity's 'increasing tendency to become integrated into an international community', unless an attempt were made to assess the outcome of this 'tendency' as reflected in the current state of the world. Today, few events remain local. Information on any major or minor occurrence is communicated to seemingly almost everyone immediately, and an action undertaken in one part of the world inevitably has global repercussions. Those who experience this 'planetarization' sense the 'integration' of all human beings into an international community less as a 'tendency' than as a *fait accompli*. But what about the vast excluded majority of people, who pose the question in completely different terms. What they seem to ask is: can a 'common patrimony of humanity' be achieved solely through an integration based on scientific and technical developments? What then can we do to ensure an equal access to such means for all, when the more fundamental task of reducing existing differences in the very standards of living lags far behind?

The idea of writing a history of the development of humankind was first put forward by Julian Huxley, the executive secretary of the Preparatory Commission of UNESCO. In 1946, Huxley wrote that 'the chief task before the Humanities today would seem to be to help in constructing a history of the development of the human mind, notably in its highest cultural achievements'. He underscored the major role that historians would play in the realization of what he called a 'gigantic enterprise'. Huxley later outlined a project that was to be submitted to the future UNESCO. In 1950, in accordance with the resolution passed by the General Conference of UNESCO, an International Commission was set up and the publication of a *History of the Scientific and Cultural Development of Mankind* (in six volumes) was approved. The first volume appeared in 1963.

How was this 'gigantic enterprise', conceived by Huxley, judged? In most cases, the volumes were not well received by critics. They did not question the data included. Rather, they mainly objected to the criteria for the selection of data and the interpretations advanced. Yet a closer look at these criticisms revealed that, skilled as they were at pointing out certain flaws and misconceptions, these commentators hardly proposed concrete suggestions that would improve the work in the future. On the whole, however, we were left with the impression that, notwithstanding its shortcomings, a very large number of readers found the work commendable, particularly as a first step towards achieving an 'essential task'.

No elucidation – rational or otherwise – of the origins or the evolution of humankind can be offered once and for all, as if by divine revelation. Writing a history of the development of humankind necessarily constitutes an undertaking that one has to return to over and over again. Nearly thirty years passed before UNESCO decided to resume an enterprise that could by no means be regarded as finished. Requested by the new Member States, a recasting of the first edition deserved the wholehearted support of all those who helped establish the Organization. The changes that had taken place since the project's inception rendered necessary and amply justified a revision and re-evaluation of history, and the members of the International Commission were the first to acknowledge such a need. There were, of course, other and more imperative reasons. Two of these should be pointed out here.

The first concerns developments in the area of research methodology. Since the 1960s, historical knowledge has increased considerably and has turned from factual history to a greater interest in anthropological research. The added

insight offered by present studies – however imperfect they may be – deserves to be transmitted to a larger public. The second and perhaps less obvious reason derives from the role that the writing of history can, and should, play in increasing our level of awareness. Writing, or as in the present case, rewriting the history of human scientific and cultural evolution requires not only taking stock of the new data available, but also helping to evaluate and assess the various implications – positive as well as negative – of all changes that have occurred. Justifying science in the name of all its benefits and advantages amounts to refusing to accept the damaging effects it can have. We have gradually become accustomed to the presence of many latent nuclear volcanoes without compensating for the technological risks. Not enough has been done to counterbalance the excessive monetary investments needed to build up such arsenals with sufficient funds to help confront the problems afflicting certain segments of humanity. Technological development has also begun to seriously endanger animal and plant life on our planet. Factors such as these remind us of the need for greater vigilance.

Universal histories and histories of the world abound. So many have been published and continue to be published that one could question the need to produce yet another one. No doubt many readers will be surprised at this venture. Each in his own way will of course judge the relative value of this new edition. There is, however, one major difference: other works of history enjoy a certain freedom that has in a sense been denied to the present one. They are free to choose themes, periods and regions that best suit the demands of a particular readership and a specific conception of history. Such works can thereby claim a certain cohesiveness, which also helps establish a certain uniformity of expression and style. The present work has been founded on an entirely different principle: the greatest possible diversity. This diversity proved to be, on the one hand, so great that it is difficult to stop it from becoming disparate and, on the other hand, not great enough to allow for a convenient regrouping of elements into types. The fault lies not in the venture itself or in those who took up the task. It lies mainly in the present state of historical knowledge. The analytic nature of historical research today blocks the way to synthesis and to the kind of approach required in the writing of history that can be considered truly universal.

This work can serve only as a history of the world and not as a universal history. This, of course, is already a considerable achievement. We should not count on the diffusion of universalism, which is the subject of inquiry by a very small, privileged minority, as long as all cultures are not equally represented and historians from all parts of the world are not endowed with the same means and cannot claim the same status, social and otherwise.

Not claiming to attain the unattainable does not, however, mean renunciation. The roads to universalism are full of twists and turns. But, they all lead to the same destination; one history for one united world. Since this history could not reach the highest common factor, it had to tend towards the lowest common multiple. And in this respect, the present work has not failed in its mission.

In 1950, we elaborated in three days a plan that would take eighteen years to complete. With a view to ensuring unity of style and presentation, we decided that each of the six volumes should be written by a single author. Such ideas

had to be abandoned. Some thirty years later, the New Commission decided to take more time over the distribution of the work to be included in seven, rather than six, volumes. Moreover, each volume would be coordinated with the others and as many authors as necessary would be called upon to cover a wide range of fields. The selection of the criteria on which the new history would be based first led to a detailed examination of the comments made by the readers of the first edition. After much debate, all agreed that it would not be satisfactory to simply juxtapose a series of regional histories. One of two possible solutions had to be chosen: dividing history either into themes or into periods and analysing each according to themes and regions. The first option – an idea that had already been put forward before 1948 – would perhaps have helped bring out in a more significant manner the factors that render manifest the common destiny of humankind. But the state of historical research at that time, which in most cases and owing to an ever-increasing acquisition of skills proceeded in the form of temporal as well as regional specializations, constituted a real obstacle to the realization of such a scheme. It was therefore decided that each of the seven volumes would be devoted to a single period and would contain a thematic and regional section.

Yielding to the constraints imposed by the state of knowledge and research did not, however, solve all problems. The idea of splitting the past into defined periods pleased no one, since most historians tend to view it as an organic whole. But, taking everything into consideration, had the objective been to separate one cultural component from another or, for example, the physical from the cultural or the religious from the profane, this act of surgery would have turned into an exercise in vivisection. Opting for the lesser evil, the Commission thus decided to proceed by chronological sections. This, at least, allowed for the preservation of a certain unity within each group.

Already in the 1950s, it had become evident that the form of periodization upheld by the European tradition loses its meaning when applied to the other parts of the world. Terms such as 'antiquity', 'the Middle Ages' or 'modern times' have little significance insofar as Asia is concerned, and perhaps even less for Africa. Admittedly, we continue using such terms for the sake of convenience. We cannot totally discard them, but we should try at least not to trust them fully.

The importance of each period is measured more in terms of what humankind has contributed to each than in terms of a duration defined by astronomy. The 'Great Discoveries' of the sixteenth and the seventeenth centuries led to some spectacular changes in the history of the world. A sudden growth of ideas and of commercial capitalism accompanied by or resulting from military conquest gave rise to migrations that brought about the creation of a new map of the world and new conceptions of humanity's destiny. This moment marks a turning point that we have ever since perceived as an acceleration of history. It was, therefore, decided that three volumes of the present work would be devoted to the period following these significant changes and transformations, while four volumes would cover the entire preceding period, starting from the origins of humankind and leading up to the sixteenth century. The Commission also decided to devote an increasing number of pages to recent years. The fifth volume thus covers three centuries; the sixth, one and a half, while the seventh spans a single century.

A word of caution is, however, in order. We often make use of a concept of progress that is based on the quantitative and not the qualitative value of achievements. Manufactured goods, consumer items and exchanges, whether they concern concrete objects or ideas, can be more or less quantified. But, as we do not posses any means of measuring happiness or well-being, we cannot infer from this that the quantitative and the qualitative value of this progress is the same, particularly insofar as the world in general is concerned. Moreover, this notion of progress should not hinder a proper appraisal of all that was contributed to history by our ancestors, to whom we owe our existence and our way of living.

Great care was taken to avoid placing undue emphasis on what could be considered the European landmarks of history. The years 1789 and 1914, although highly significant in the history of Europe, served only nominally as points of reference. It was understood that, depending on the case, the ethnocentrism implied by these dates would be reduced as much as necessary through a proper and adequate treatment of the issues preceding or following them. Similarly, to avoid falling into the traps of Western traditionalism, it was considered necessary to cease using the Christianization of the Roman Empire as a mark of the end of the Ancient World and the beginning of the Hegira, in the third volume, which covers the period from 700 BC to AD 700 , the middle of which comes before the beginning of the era acknowledged – belatedly – also by Muslims.

The Commission's choice does not conflict greatly with the Chinese system of dating, because around the same epoch the same phenomenon appeared in both the east and west of Eurasia: the awakening of tribes in these Central-Asian steppes, who until then had been restricted to a disorderly, Brownian form of movement of particular groups, and who henceforth united and set off to conquer the largest empire the world has ever known. Events such as this draw our attention to the advantages of following a calendar determined not by the permanent aspects of the planets but by climatic variations. Indeed, the Mongols would not have reached such a degree of power had the climate not favoured the humidification of the pasturelands that nourished their horses. However, it will be a while before a calendar based on climatic variations is available. We still lack information on some vital factors: the evaluation of harvests, the extension or the regression of lacustrine and forest areas, phytographical analyses, and so on. Only when we have obtained such necessary data can we think of establishing a new type of periodization that can be verified through meteorological calculations extrapolating and applying to the past our present conjectures about the influence of solar explosions on the atmosphere.

The period to be treated in Volume IV was therefore set by the end of Volume III (the seventh century AD) and the beginning (the sixteenth century AD) of Volume V. Volumes I and II have been devoted to the many thousands of years constituting the origins of humanity. The richness of the new data at our disposal made it necessary to treat separately the period extending from the third millennium to the beginning of the seventh century BC.

The division into seven volumes was dictated by a combination of factors ranging from the abstract to the practical – including ensuring the more or less equal size of the volumes – in keeping with historical facts. Beyond all specific differences, five principal stages can be recorded in human evolution: (1) the use of materials and tools accompanied by the emergence of cultures; (2) the moulding of a geopolitics or a geo-culture signalled by the appearance of major works of all kinds, all of which were to be of lasting value; (3) partitive convulsions that forced in advance the distinction of cultural identities through the play of mutual influences; (4) conceptions resulting from a closed human universe whose planetary course lies within a limitless space; and (5) the intensification of centres of development under the pressure of a form of capitalism that has become industrial and an industry that is becoming scientific. The seventh volume will thus deal with the issue of these new currents and the tidal waves that they provoke: facets that lead to the birth of a new type of polarization and as a result of which traditional cultures fall into abeyance.

Such bird's-eye views as those offered here are not misleading because they are crude; they seem questionable because they escape our sight when we remain too close to the ordinary facts, and in this regard we mainly confront the limitations of our methods of research. No one is unaware of the difficulties inherent in all attempts to provide a synthetic view of humankind's common destiny. There is no answer to these difficulties from which the present subdivision of each volume into themes and regions suffers – into themes that highlight the shared characteristics of all human beings, and into regions to underline human diversity.

In each volume, the thematic parts should have been the easiest to work out. Several problems were, however, encountered. In order to ensure that the cultures that benefit from the spectacular development we witness today were not favoured beyond measure, it was considered necessary to reduce the importance granted to theoretical innovations and their applications and therefore to refrain from using scientific discoveries as chronological pointers. Had this not been the case, the distribution of themes would have been a simple matter. It would have sufficed to begin with a survey of the scientific and technical knowledge acquired over a given period of time, and then to retrace the causes in their sequential order.

Just as it was necessary to tone down the privileges conferred on some by the process of evolution – and, more particularly, to question a system of values rooted in an overly univocal notion of progress – it also was necessary to standardize the distribution of themes by including more 'ordinary' references: for example, by starting with a description of the physical and natural conditions in order to arrive at the scientific through the demographic and the cultural. This not only enhanced the uniformity of the volumes but also offered the major advantage of emphasizing ways of living. Whatever these are, they must first satisfy the basic physiological needs – a vital minimum dictated by the instincts of survival and rendered partially relative by the differences of climate. Each culture responds to this in its own manner, and accords as much to its natural environment as to the habits that it inherits. Certain acquired needs are then added to this vital minimum – superfluous needs become necessary and established in varying degree according to the social hierarchies and geohistorical differences. Moreover, as human beings are not only biological but also thinking and feeling entities, each material culture is accompanied by a culture that can be called 'spiritual' in the widest sense of the term, and that also varies according to the situation. Finally, even though

the conditions are not identical, material culture and spiritual culture are interrelated.

This enunciation of the common grounds on which all human lives are established stands to reason and would seem evident to any lay person. It could also, however, lead us to think that it is easy to find historians ready to develop each theme. The present state of historical knowledge proves that this is not so and, as always, for the same reason. Insignificant as this problem may be, the solution lies in abandoning analytical methods and adopting a synthetical approach.

Undoubtedly, current research and investigations help us in our evaluation of material and spiritual cultures, but separately. We are completely ignorant about the interconnections between the two. Where does this notorious deficiency come from? Two main causes can be advanced.

The first concerns the elaboration of a global history. Indeed, when it comes to local or regional histories, each confined to a particular epoch, the data we possess helps us either to deal with some of the problems or to contribute by offering some information. But when one problem or another needs to be looked at from a global point of view, we confront a major dilemma: which elements of the available data should be included in an inventory of an absolutely common heritage? In other words, which advances made at one place or another, or at one point of time or another, effectively contributed to what can be called 'general progress'? The workshops of historians can boast of few (if any) historians who specialize in the evaluation of 'generalities'! When the need for one arises, then it must be admitted that the courageous few who undertake such a task suffer from the absence of sufficient information and are compelled to work in conditions that make their achievements all the more admirable but considerably curb their influence.

This first cause leads to the second: the absence of criteria that would make it possible to distinguish effectively the subjective from the objective, as much in the work accomplished as in the reputations won. Here we touch upon an issue that is too important to dismiss without further discussion.

Studies on primitive or savage societies, particularly those conducted since the mid-twentieth century, carried anthropology to a high degree of what must be called the 'intelligence' of cultures. In these societies, myth plays a fundamental role. It legitimizes matrimonial and social behaviour as well as customs and ways of living – the way one eats, dresses and organizes one's life inside and outside the dwelling. In an even more significant manner, it legitimizes one's spiritual behaviour as much in times of war as in peace. This global aspect of myth itself leads us to the heights from which, at a glance, we can view not only the various behaviours as a whole, but also the very logic that sustains them.

Historical evolution disperses myth, without, however, abolishing the mythological function. It provokes the growth of branches and favours ramifications. What had developed thanks to myth, religion and literature (moral and political), art and technique breaks up later into more and more subdivided areas of knowledge: differentiations that lead to the belief that the logic of myth or of the sacred is challenged by that of 'Science', a word that obstructs more than all others what we term historical intelligence. In the

original sense of the word, 'science' means knowledge, with no distinction implied between knowledge and know-how. Today this word has taken on such a specific meaning that, for a vast majority of the most highly informed minds, science denotes truth, as opposed to the falsity of myth. Yet, many eminent scholars acknowledge that this 'truth' contains a part of myth and that it is indeed thanks to this that methods and knowledge advance. It is by working within the mythological that we reduce the part of myths, elements of which always survive in the very heart of science.

The barriers that have been most resolutely built against the 'intelligence' of history have their sources in the gradual formation of separate enclaves of investigation. Social, economic, political, literary history and so on – each domain follows its worn path and rarely meets the other, or never enough to allow for the establishment of criteria common to all that could constitute the basis for a truly universal history of scientific and cultural development. The worst form of such separation can be found in the cosmic distance that has been introduced between the history of religion and that of science, and this in spite of some highly remarkable, though rare, attempts to make them move towards each other via the social and the philosophical domains. No significant results should be expected until the gaps between ordinary language and scientific language are bridged, particularly when the latter makes use of mathematical terms so fully exploited by the initiated few and so inaccessible to the secular masses.

This brings us back to the question of the limitations of this edition referred to earlier: limitations concerning the basic logical presuppositions on which a truly universal history of humankind should be founded. It is only on the basis of certain common features that one culture can comprehend something that is part of another culture and that the people of today can understand a little of what lies in the past. But then, given the present state of our knowledge and the manner in which the basic logical presuppositions are handled, our history will remain beyond the reach of the general public – however enlightened – for which it is intended.

Nonetheless, a certain merit – perhaps less significant than hoped for – makes this second edition worthy of our attention. By eliminating the notion that the cultures rendered marginal by 'progress' represent groups of people 'without history', the study of cultures wherein myth is dispersed among all kinds of domains could only gain from the experience of those whose lives are, even today, steeped in a mythology that they all consider fundamental. We have not yet reached our goal, but the step taken marks a definite improvement in terms of our understanding of history. And, as readers will discover, it is this aspect of the thematic part of each volume that makes this work truly exceptional.

We now come to the question of the treatment of regions in each volume. To begin with, let us look at a major ambiguity that threatened the very conception of these sections. An example will suffice. To which region does Newton belong? To Cambridge? England? Europe? The West? The world? There is no doubt that the universality of his law of gravitation makes him a part of the common heritage of humanity. Yet, undoubtedly this law discovered by a particular man, at a particular place and point of time, would seem to have miraculously descended from the skies if we did not take into account the facts of the discovery, the

circumstances leading to it and the manner in which the law was adopted by all. Should we have then talked about Newton in one way in the thematic chapter and in another in the regional? Although the difficulties involved in solving such a problem are great, they turn out to be less so when confronted with yet another problem that would have resulted from any attempt to merge the two parts into one; for, in that case, the question would have been, 'which one?' A fusion of all into the regional would, to a great extent, have simplified the task, given that we are dealing with specializations in different fields. But it would have led to the very unpleasant need to emphasize the merits of one culture at the cost of the others. A fusion of all into the thematic? In that case, Newton's law would have been stripped of its socio-cultural characteristics and this would have led to some kind of sanctification of the 'genius'. Needless to say, our observations concerning Newton apply to all thinkers and discoverers and to all that humankind has created.

Some readers will perhaps regret the fact that this history, whose dominant note is certainly transcultural, does not succeed better in overcoming certain problems resulting from habits and preconceived notions. We all talk about 'Asia' and 'Europe'. Originally, these were names given to Greek nymphs and, together with Africa, were used to distinguish the three principal, cardinal points of the world perceived by the Mediterranean navigators: the east, the north and the, south respectively. As for the continent of America, its name was curiously given to it by a cartographer who, while outlining a map of this continent, used the information supplied to him by Amerigo Vespucci. In the case of the nymphs as well as in that of the cartographer, we can no longer distinguish the subjective from the objective. What was in fact a very subjective decision in the first place now appears to be very objective because it is commonly accepted by everyone. We cannot change something that has been so firmly established over the years, but the often very serious problems and disadvantages that result from the ethnocentrism implied by such customs need to be pointed out.

Depending on the epochs, Egypt is at times best understood when considered as African and at others when its civilization is regarded as having acquired much of its significance from a dual Nile-Euphrates identity. Similarly, instead of remaining Mediterranean, southern Europe became continental when the centre of gravity of exchanges and developments shifted to the Atlantic. China constitutes another example. This Middle Kingdom felt the effects of the existence of other continental regions when its Great Wall no longer protected it from the conquerors it later tried to assimilate, or when it yielded perhaps for too long a period, to the attack of the seamen and naval forces coming from the other end of the world, that is, from Europe.

Geographical perspectives change from one era to another. But it is difficult to incorporate such changes and align them with the periodization adopted for a publication devoted to history. Those responsible for planning the seven volumes had to devise the ways and means of solving such problems. At times, they had to resort to certain subterfuges so as to prevent the periodization from turning into some kind of a jigsaw puzzle and requiring frequent rearrangement. This entailed, however, the risk of introducing certain anachronisms.

Such risks are in no way negligible. To a modern mind, for example, the commerce or the conquests in ancient times across the deserts of Sinai appear as manifestations of the hostilities existing between Africa and Asia. This distinction between the two continents becomes nonsensical when applied to the period when Egypt did not consider itself as African, Assyrian or Asian. Each region perceived itself first as constituting the whole universe or as representing the whole universe as defined by its own gods. We must be aware of the dangers of accepting such ideas, which still survive in the unconscious, for they may affect our conscious minds and foster notions of rights and privileges detrimental to the development of universalism.

The need to determine the number of pages to be devoted to each 'contingent' arose from certain customs that, although anachronistic, sometimes generate very strong opinions and influence our decision. It also arose from the fact that the distrust of ethnocentrism expressed itself in terms that were very ethnocentric. Including Cro-Magnon man in an inventory of 'European' sites amounts to attributing to him a label that contradicts all that was felt in times when existence could not be conceived of except in terms very different from those related to our planetary territoriality. Similarly, the concept of Africa was itself foreign to the African empires of kingdoms, each constituting for itself a world in itself and, at the same time, a work that belongs to all. Readers will understand such imperfections, which have resulted from a need to adopt a pragmatic approach.

Applying modern notions of geography to any period of the past relieves us of the dizziness felt when we look down into the immense depths of time, yet it is in these depths that cultural but also natural interactions, direct or indirect, multiplied: a swarming mass much too indecipherable to allow for the delineation of linear ancestry. Physical evolution leads perhaps to the formation of races, but as the human species can be known through its customs, faculties and cerebral activities, this privilege common to all reduces practically to nothing the particularisms that some – not always disinterested – viewpoints defined formerly as racial.

The human species cannot really be differentiated except as ethnic groups and through customs that defy any simplistic typology. A strong capacity for adaptation, peculiar to humans, enables them to invent a practically limitless number of solutions to the problems posed by all kinds of environments, and even more so by circumstances that the smallest events modify and great events transform altogether. In this lies the most amazing aspect of history: the infinite variety of answers that each individual or collectivity finds to the questions put to it by destiny. The more history accelerates its pace and becomes more specific, the more our destiny becomes enigmatic. This is because every human being is a human being, and no single one resembles another.

The demise of the colonialists who believed or claimed to be the civilizers of this world led to the birth of many new nations and many new member states of international organizations. 'New' in what sense? The establishment of a 'new World Order' is bound to remain a utopian idea as long as history has not explained how a local body of historical cultures finally engendered what it has over the centuries referred to as 'civilization': a world full of contradictions. Intended as universal and respectful to other cultures, this civilization has turned out to be materialist and destroyed many cultures as a result of the superiority

that it attributed to its own system of laws and rights. Two challenging tasks thus face historians: acknowledging the universalism that lies hidden beneath all particularisms and agreeing among themselves on what should be made generally known in this respect.

An elucidation of the past requires personal as well as collective efforts. This twofold process should have found spontaneous expression in a work meant to aid the advancement of knowledge. The Commission recommended therefore that, in addition to the thematic and regional parts, a third part be added that would have comprised specific supplements on details that needed developing, problems that needed solving, and finally a presentation of different and opposing opinions on interpretations in dispute. This project met with overwhelming difficulties, and some explanation is called for.

This international history, which had been conceived as a result of dialogues and discussions, would evidently have gained considerably from a presentation of the differences in interpretation in their proper dimensions. It would have been more lively and instructive and have given readers more food for thought. Unfortunately, the dispersion of authors to be included and chosen from the whole world demanded means and time that were unavailable. The editors, who had already undertaken a tremendous amount of work, could not have successfully completed this additional task without assistance, in particular from specifically chosen committees. Taking into account the costs of travel and accommodation, the already high cost of the operation would have nearly doubled. No doubt a day will come when, debates on themes and regions being easier than they are now, it will be possible to expound history as it is revealed by a confrontation of knowledge and viewpoints on particular questions concerning all humanity.

Until the state of knowledge and of historical research in the world has reached this convergent point, we are obliged to give up the idea of showing the divergences that future historians will have to face. We have, however, provided notes at the end of articles, which have been written so as to ensure maximum diversity and the broadest possible participation. A certain degree of arbitrariness persists, of course. But this is unavoidable as long as the excesses that analyses lead to are not minimized through the elaboration of syntheses based on criteria derived from irrefutable logical presuppositions – presuppositions that help establish universal certitudes. Let us not forget, however, that innovations originate only within the gaps of certitude.

One of the merits of this work resides in the fact that it has succeeded in enlisting the collaboration of a very large number of people, representing a large number of regions and cultures. The Commission also encouraged the formation of local working groups responsible for obtaining and organizing the data to be included in the various chapters. This present work marks perhaps only the beginning of such collective efforts. Nevertheless, it enables us to anticipate satisfactory results. Knowing oneself well in order to make oneself better known constitutes a major contribution to mutual understanding. In this respect, historical research resembles an unearthing of unconscious phenomena. It brings to light that which in the nocturnal depths of individual or collective existences gives them life, so to speak, in spite of themselves or against their will.

This publication will no doubt give rise to much criticism. Even if these critical responses turn out to be harsh, they will justify the project, whose main objective is to arouse us from our dogmatic slumber. Historical events take care of this much more efficiently, but at a much higher price.

# GENERAL INTRODUCTION

*Georges-Henri Dumont*
*President of the International Commission*

Societies are making greater demands than ever on history, but urgent as they might be, these demands by various groups are not altogether straightforward. Some societies look to historians to define their identity, to buttress the development of their specific characteristics or even to present and analyse the past as confirming a founding myth. Conversely, other societies, influenced both by the *Annales* school of historiography and by the geographical, chronological and thematic enlargement of history, aspire to the building of bridges, the ending of self-isolation and the smoothing out of the lack of continuity that is characteristic of the short term.

In 1946, those attending the meeting of the first Preparatory Commission of UNESCO agreed that it was part of the fundamental mission of the United Nations Educational, Scientific and Cultural Organization to lay the foundations for a collective memory of humanity and of all its parts, spread all over the world and expressed in every civilization. The International Scientific Commission came into being four years later with the apparently gigantic task of drafting a *History of the Scientific and Cultural Development of Mankind*. Publication of the six volumes began in 1963, marking the successful conclusion of an international endeavour without parallel, but not without risks. Success with the general public was immediate and lasting, notwithstanding the reservations expressed by the critics, who often found certain choices disconcerting but who were not consistent in the choices and interpretations they proposed as alternatives.

Considering the amount of time required to prepare it, the first edition of the *History* must be seen as a daring achievement. Although it had a number of faults inherent in the very nature of historical knowledge, it nonetheless opened up new avenues and encouraged further progress.

In 1978, the General Conference of UNESCO decided to embark on a new and completely revised edition of the *History* because it realized that along with the considerable development of historiography – the improvement in what are called its auxiliary sciences and its growing links with the social sciences – there was an extraordinary acceleration of day-to-day history. What it did not know, however, was that the pace of this acceleration would continue to increase, bringing profound changes to the face of the world.

It scarcely needs saying that the task laid upon the International Scientific Commission, under the chairmanship of the late Paulo E. de Berrêdo Carneiro and then of my eminent predecessor, Professor Charles Morazé, was both enormous and difficult.

First of all, international teams had to be formed, as balanced as possible, and cooperation and dialogue organized between the different views of the major collective stages in the lives of people, but without disregarding the cultural identity of human groups.

Next, attention had to be given to changes in chronological scale by attempting a scientific reconstruction of the successive stages of the peopling of our planet, including the spread of animal populations.

Lastly, steps had to be taken to ensure that traditional methods of historical research, based on written sources, were used side by side with new critical methods adapted to the use of oral sources and contributions from archaeology, in Africa for the most part.

To quote what Professor Jean Devisse said at a symposium in Nice in 1986 on 'Being a Historian Today': 'If we accept that the history of other people has something to teach us, there can be no infallible model, no immutable methodological certainty: listening to each other can lead to a genuine universal history'.

Although historians must be guided by a desire for intellectual honesty, they depend on their own views of things, with the result that history is the science most vulnerable to ideologies. The fall of the Berlin Wall a few weeks after I assumed the presidency of the International Commission symbolized the end of a particularly burdensome ideological division.

In a way, the impact of ideologies will be lessened by the fact that the chief editors of each volume have sought the invaluable cooperation not only of experienced historians but also of renowned specialists in disciplines such as law, art, philosophy, literature, oral traditions, the natural sciences, medicine, anthropology, mathematics and economics. In any event, this interdisciplinarity, which helps avoid error, is undoubtedly one of the major

improvements of this second edition of the *History of Humanity* over the previous edition.

Another problem faced was that of periodization. It was out of the question to systematically adopt the periodization long in use in European history – i.e., Antiquity, the Middle Ages, and modern times – because it is now being extensively called into question and also, above all, because it would have led to a Eurocentric view of world history, a view whose absurdity is now quite obvious. The seven volumes are thus arranged in the following chronological order:

Volume I      *Prehistory and the Beginnings of Civilization*
Volume II     *From the Third Millennium to the Seventh Century* BC
Volume III    *From the Seventh Century* BC *to the Seventh Century* AD
Volume IV    *From the Seventh to the Sixteenth Century*
Volume V     *From the Sixteenth to the Eighteenth Century*
Volume VI    *The Nineteenth Century*
Volume VII   *The Twentieth Century*

It must be stated at once that this somewhat surgical distribution is in no way absolute or binding. It will in no way prevent the overlapping that there must be at the turn of each century if breaks in continuity and the resulting errors of perspective are to be avoided.

In his foreword, Professor Charles Morazé has clearly described and explained the structure of each of the volumes, with a thematic chapter, a regional chapter and annexes. This structure, too, may be modified so as not to upset the complementarity of the pieces of the mosaic.

Having completed their work, the International Scientific Commission, the chief editors of the volumes and the very large number of contributors will now be able to adopt as their motto the frequently quoted saying of the philosopher Etienne Gilson:

We do not study history to get rid of it but to save from nothingness all the past which, without history, would vanish into the void. We study history so that what, without it, would not even be the past any more, may be reborn to life in this unique present outside which nothing exists.

This present will be all the more unique because history will have shown itself to be not an instrument for legitimizing exacerbated forms of nationalism, but an instrument, ever more effective because ever more perfectible, for ensuring mutual respect, solidarity and the scientific and cultural interdependence of humanity.

# THE INTERNATIONAL COMMISSION

## for the New Edition of the History of the Scientific and Cultural Development of Mankind

---

**President:** G.-H. Dumont (Belgium)

**Members of the International Commission:**
I. A. Abu-Lughod (Palestine) (deceased)
A. R. al-Ansary (Saudi Arabia)
J. Bony (Côte d'Ivoire)
E. K. Brathwaite (Barbados)
G. Carrera-Damas (Venezuela)
A. H. Dani (Pakistan)
D. Denoon (Australia)
M. Garasanin (Former Yugoslavia, Fed. Rep. of)
T. Haga (Japan)
I. D. Thiam (Senegal)
F. Iglesias (Brazil) (deceased)
H. Inalcik and S. Akşin (Turkey)
S. Kartodirdjo (Indonesia)
J. Ki-Zerbo (Burkina Faso)
C. Martinez-Shaw (Spain)

E. Mendelsohn (United States of America)
E. M'Bokolo (Democratic Republic of the Congo)
J. H. Kwabena N'Ketia (Ghana)
T. Obenga (Congo)
B. A. Ogot (Kenya)
Pang Pu (China)
W. Sauerlander (Germany)
B. Schroeder-Gudehus (Mrs) (Canada)
R. Thapar (Mrs) (India)
I. D. Thiam (Senegal)
K. V. Thomas (United Kingdom)
S. L. Tikhvinsky (Russian Federation)
N. Todorov (Bulgaria) (deceased)
G. Weinberg (Argentina)
M. Yardeni (Mrs) (Israel)
E. Zürcher (The Netherlands)

**Bureau of the International Commission**
A. R. al-Ansary (Saudi Arabia)
E. K. Brathwaite (Barbados)
G. Carrera-Damas (Venezuela)
A. H. Dani (Pakistan)
E. Mendelsohn (United States of America)

R. Thapar (Mrs) (India)
I. D. Thiam (Senegal)
K. V. Thomas (United Kingdom)
S. L. Tikhvinsky (Russian Federation)
N. Todorov (Bulgaria) (deceased)

**Former Members**
E. Condurachi (Romania) (deceased)
G. Daws (Australia)
C. A. Diop (Senegal) (deceased)
A. A. Kamel (Egypt) (deceased)

M. Kably (Morocco)
H. Nakamura (Japan)
J. Prawer (Israel) (deceased)
S. Zavala (Mexico) (deceased)

**Honorary Members**
S. A. al-Ali (Iraq)
P. J. Riis (Denmark)
T. Yamamoto (Japan)

**Former Presidents**
P. E. B. Carneiro (Brazil) (deceased)
C. Morazé (France) (deceased)

**Secretariat (UNESCO)**
K. Stenou (Mrs), Director, Division of Cultural Policies and Intercultural Dialogue
A. Moussa Iye, Chief, Section of Intercultural Dialogue
R. Lo Giudice, Programme Specialist
K. Touré (Ms), Secretary

# HISTORY OF HUMANITY
## SCIENTIFIC AND CULTURAL DEVELOPMENT
## IN SEVEN VOLUMES

———————

VOLUME I
*Prehistory and the Beginnings of Civilization*

Editor:      S. J. De Laet (Belgium) (deceased)
Co-Editors:  A. H. Dani (Pakistan)
             J. L. Lorenzo (Mexico) (deceased)
             R. B. Nunoo (Ghana)

VOLUME II
*From the Third Millennium to the Seventh Century* BC

Editors:     A. H. Dani (Pakistan)
             J.-P. Mohen (France)
Co-Editors:  C. A. Diop (Senegal) (deceased)
             J. L. Lorenzo (Mexico) (deceased)
             V. M. Masson (Russian Federation)
             T. Obenga (Congo)
             M. B. Sakellariou (Greece)
             B. K. Thapar (India) (deceased)
             Xia Nai (China) (deceased)
             Zhang Changshou (China)

VOLUME III
*From the Seventh Century* BC *to the Seventh Century* AD

Editors:     E. Condurachi (Romania) (deceased)
             J. Herrmann (Germany)
             E. Zürcher (The Netherlands)
Co-Editors:  J. Harmatta (Hungary)
             J. Litvak King (Mexico)
             R. Lonis (France)
             T. Obenga (Congo)
             R. Tapar (Ms) (India)
             Zhou Yiliang (China)

VOLUME IV
*From the Seventh to the Sixteenth Century*

Editors:     M. A. al-Bakhit (Jordan)
             L. Bazin (France) (deceased)
             S. M. Cissoko (Mali)
             A. A. Kamel (Egypt) (deceased)

Co-Editors:  M. S. Asimov (Tajikistan) (deceased)
             P. Gendrop (Mexico) (deceased)
             A. Gieysztor (Poland) (deceased)
             I. Habib (India)
             Y. Karayannopoulos (Greece)
             J. Litvak King/P. Schmidt (Mexico)

VOLUME V
*From the Sixteenth to the Eighteenth Century*

Editors:     P. Burke (United Kingdom)
             H. Inalcik (Turkey)
Co-Editors:  I. Habib (India)
             J. Ki-Zerbo (Burkina Faso)
             T. Kusamitsu (Japan)
             C. Martínez Shaw (Spain)
             E. Tchernjak (Russian Federation)
             E. Trabulse (Mexico)

VOLUME VI
*The Nineteenth Century*

Editors:     P. Mathias (United Kingdom)
             N. Todorov (Bulgaria) (deceased)
Co-Editors:  S. al Mujahid (Pakistan)
             A. O. Chubariyan (Russian Federation)
             F. Iglesias (Brazil) (deceased)
             Shu-li Ji (China)
             I. D. Thiam (Senegal)

VOLUME VII
*The Twentieth Century*

Editors:     S. Gopal (India) (deceased)
             S. L. Tikhvinsky (Russian Federation)
Co-Editors:  I. A. Abu-Lughod (Palestinian Authority)
             (deceased)
             I. D. Thiam (Senegal)
             G. Weinberg (Argentina)
             Tao Wenzhao (China)

*All maps drawn by Nicolas Merlet*

# THE CONTRIBUTORS

**Abdel-Malek, Anouar** (Egypt). Field: social sciences. Director of research, Ecole des Hautes Etudes en Sciences Sociales (EHESS), Paris.

**Abu-Lughod, Ibrahim A.** *deceased* (Palestine–United States). Field: social sciences. Former Chairman of the Political Science Department, Northwestern University (Chicago); Vice-Chairman and Professor of international relations, University of Birzeit; co-founder and editor of the *Arab Studies Quarterly*; member of the Palestinian National Council.

**Ade-Ajayi, Jacob Festus** (Nigeria). Field: nineteenth-century West African history. Former Vice-Chancellor of the University of Lagos; member of the scientific council of the UNESCO *General History of Africa*; Professor Emeritus.

**Anisuzzaman** (Bangladesh). Fields: Bengal literature, culture, identity and history. Professor, Department of Bengali Literature, Dhaka University Abash, Bangladesh; former Chairman of the Bangla Academy.

**Baghli, Sid Ahmed** (Algeria). Fields: art, art history and cultural heritage. Former Director of the Algerian museums; member of the scientific advisory board of Institut National du Patrimoine Maghrébin, Tunis; adivsor for the Algerian delegation to UNESCO.

**Bah, Thierno** (Guinea–Cameroon). Field: military history of Central Africa. Founding member of the Association of African Historians, University of Yaoundé.

**Bahemuka, Judith M.** (Kenya). Field: sociology. Teaches in the sociology department and holds the UNESCO Chair on Women, Basic Education, Health and Sustainable Development at the University of Nairobi; Ambassador of Kenya to the United Nations.

**Basu, Aparna** (India). Fields: modern Indian history, history of education, women's history. Former Professor of history at the University of Delhi; visiting fellow, Wolfson College,

Cambridge (UK); President of the All India Women's Conference, New Delhi.

**Becker, Jörg** (Germany). Fields: communications, media and information technologies. Professor of political science, Marburg University; Managing Director of the KomTech-Institute (Solingen).

**Beckles, Hilary Macdonald** (Jamaica). Field: Caribbean history. Pro-vice chancellor, University of the West Indies (UWI), Kingston, Jamaica. Professor of social and economic history, Department of History, UWI. Member of the International Task Force for the UNESCO ASPnet Transatlantic Slave Trade Education Project.

**De Benoist, Joseph-Roger** (France). Field: contemporary history of French-speaking West Africa; former Director of research, Institut Fondamental d'Afrique Noire Cheikh Anta Diop, Dakar; member of the Académie des Sciences de l'Outre-mer, Paris.

**Bensimon, Marc** (United States). Field: French literature (Renaissance, Baroque, modern and comparative literature and art). Professor of French Emeritus, University of California at Los Angeles.

**Borissov, Yuri S.** (Russia). Field: cultural history of central and south-east Europe. Researcher, Institute of Slavic and Balkan Studies of the Russian Academy of Sciences.

**Carrera Damas, Germán** (Venezuela). Field: history. Founder of the Chair of Theory and Method of History; Professor, Central University of Venezuela.

**Cartier, Michel** (Canada). Field: communications. Faculty member, University of Quebec (Montreal); consultant in new information and communication technologies.

**Chilundo, Arlindo Gonçalo** (Mozambique). Field: economic and social history of Africa; Associate Professor of history and Director and Coordinator of studies, University of Eduardo Mondlane, Mozambique.

**Chojnowski, Andrzej** (Poland). Field: history. On the history faculty of Warsaw University and also affiliated with the Mordechaj Anielewicz Center for the Research and Teaching of the History and Culture and Jews in Poland, founded in 1990.

**Chondge, Cheng** (China). Field: Chinese history. Director and research fellow, Institute of Qing Dynasty History, People's University; Vice-Chairman of the National Committee on Compiling the Qing Dynasty History; President of the Chinese Association of Mongolian History.

**Clark, John** (Australia). Field: modern Asian art. Professor in the Art History and Theory Department, University of Sydney. Fellow of the Australian Academy of the Humanities; recipient of the Australian Centenary Medal (2003).

**Claval, Paul** (France). Field: human geography. Professor at the University of Paris-Sorbonne. Member of the European Academy.

**Coulibaly, Elisée** (Burkina Faso). Field: history of archaeology. Chargé de mission, Musée des Arts d'Afrique et d'Océanie (MAAO), Paris; senior researcher on the history of mines and metallurgy team, University of Paris I, Centre National de la Recherche Scientifique (CNRS), France.

**Dalby, David** (United Kingdom–France). Field: modern languages. Lecturer in modern languages, Fourah Bay College, Sierra Leone; Professor and researcher of Western African languages, School of Eastern and African Studies (SOAS) of the University of London.

**Dhammaratana, Tampalawela** (Sri Lanka). Field: comparative philosophy and Asian studies. Council member of the World Buddhist University, Bangkok. Post-doctoral UNESCO Fellow, Ecole Pratique des Hautes Etudes, University of Paris-Sorbonne, France.

**Dioume, Oumar** (Canada–Senegal). Field: mathematical economics and econometrics. Director of research and development at AirTel Com, Montreal; research in engineering mathematics and telecommunication networks; member of ASSNET (African Summit for Science and New Technologies); former lecturer at the Ecole Polytechnique, Montreal.

**Dizboni, Ali Ghanbarpour** (Canada–Iran). Field: international relations and comparative politics (Middle East and Central Asia). Assistant Professor, Royal Military College of Canada (Kingston).

**Dubet, François** (France). Field: sociology. Author of several books on social movements, the city, marginality, youth, education, work and social theory. Sociologist, University of Bordeaux II; member of the CADIS (Centre d'Analyse et d'Interventions Sociologiques, CNRS, EHESS); member of the Institut Universitaire de France; Director of studies, EHESS, Paris.

**Duchein, Michel** (France). Field: history of archives. Honorary General Inspector of the Archives de France and former head of the technical service of the Direction des Archives de France; former Editor-in-Chief of the journal of the Conseil International des Archives, *Archivum*, and *Gazette des Archives*.

**Dumont, Georges-Henri** (Belgium). Field: history. Historian, Université de Louvain; Professor Emeritus of economic and social history, ICHEC of Bruxelles. Honorary Curator, Musées Royaux d'Art et d'Histoire; member of the Académie Royale. Author of *Léopold II* (Grand Prix de la Biographie de l'Académie Française); member of the UNESCO Executive Board (1981–1989).

**Ekaya, Wellington N.** (Kenya). Fields: ecology, range management, human migration. Lecturer, University of Nairobi, Department of Range Management; member of the editorial board of the *Journal of Human Ecology*.

**Fohlen, Claude** (France). Field: economic and North American history. Professor emeritus; Chair of the American History department at the University of Paris I-Sorbonne.

**Friese, Heidrun** (United Kingdom). Field: anthropology of the sciences. Teaches in the Department of Social and Political Sciences, European University Institute, Florence (Italy).

**Gilles, Roland** (France). Field: Islamic art and culture. UNESCO expert on Oriental textiles. Responsible for collection and exhibitions, Institut du Monde Arabe, Paris.

**Goma, Lameck K. H.** (Zambia). Field: zoology. Former Vice-Chancellor, University of Zambia; Minister of Education, Foreign Affairs, and Higher Education, Science and Technology (Zambia).

**Goonatilake, Susantha** (Sri Lanka). Field: sociology of non-Western culture and science. Royal Asiatic Society of Sri Lanka.

**Gopal, Sarvepalli,** *deceased* (India). Field: modern history of South Asia. Professor Emeritus of contemporary history, Jawaharlal Nehru University, New Delhi.

**Guillaume, Astrid** (France). Fields: German language, linguistics and comparative literature. Associate Professor, Université de Besançon (France).

**Habib, Syed Irfan** (India). Field: socio-cultural and intellectual history of scientific knowledge in India. Scientist at the National Institute of Science, Technology and Development Studies, New Delhi.

**Haddad, Mahmoud, O.** (Lebanon). Field: modern Middle East history. Chairperson of the Department of History, University of Balamand (Lebanon); Former Associate Professor, History Department, Columbia University (New York). Member of the Middle East Studies Association (US).

**Hawthorn, Geoffrey** (United Kingdom). Fields: international politics and political economy. Professor of international politics, Faculty of Social and Political Sciences, Cambridge University.

**Hegarty, Seamus** (United Kingdom). Fields: Educational research, disability and special educational needs; school

reform. Director of the National Foundation for Educational Research in England and Wales.

**Houzel, Christian** (France). Field: history of mathematics, numbers and symmetry. Professor of mathematics, IUFM (Institut Universitaire de Formation des Maîtres), Paris; former Director of the *Bulletin de la Société Mathématique de France*.

**Hussain, Faheem** (Pakistan). Field: physics. Former Head of the Office of External Activities, Abdus Salam International Centre for Theoretical Physics, Trieste (Italy). Teaches physics in Pakistan.

**Iskandarov, Bahodor I.** (Republic of Tajikistan). Field: history of Tajikistan. Doctor of History and Academician; Honorary Director, Institute of History, Archaeology and Ethnography, Academy of Sciences of the Republic of Tajikistan; Avicenna Price laureate.

**Jackson, Elizabeth K.** (United States). Field: culture and mass production, Africa and African-Americans. Professor in the Department of Communications, California State University, Bakersfield.

**Jones, Caroline A.** (United States). Field: twentieth-century visual art and culture. Associate Professor of Art History, History, Theory and Criticism Section, Department of Architecture, Massachusetts Institute of Technology (MIT).

**Kane, Saidou** (Mauritania). Fields: history and international relations; integration and cultural aspects of development. Numerous professorships: Ecole Nationale d'Administration, Nouakchott, (Mauritania); UNITAR headquarters, Geneva; Sorbonne (Paris); and institutions in Belgium and the Netherlands. Promoter of human rights and African languages.

**Kebede, Alemseghed** (United States). Fields: social theory, social movements, and cross-cultural encounters. Professor of sociology, Department of Sociology and Anthropology, California State University, Bakersfield.

**Khorev, Victor A.** (Russia). Field: Eastern European literature. Deputy Director of the Institute of Slavic and Balkan Studies of the Russian Academy of Sciences.

**Kecheng, Yao** (China). Field: Oriental languages. Associate Professor, Department of Oriental Language Studies, Beijing University; council member of the Association of Mongolian Language and Literature; council member of the Association of Mongolian Republic Studies.

**Kipré, Pierre** (Côte d'Ivoire). Field: modern and contemporary African history. Professor, Université d'Abidjan.

**Kouassi Kwam Edmond** (Togo). Fields: international politics, peace and conflict studies; international African organizations. Consultant for various international organizations and NGOs; Vice-Dean of the Faculty of Law and Political Science, Université du Benin.

**Lacey, Nicola** (United Kingdom). Fields: criminal law and justice, legal and social theory. Professor of criminal law, London School of Economics; member of the Mannheim Centre for the Study of Criminology and Criminal Justice.

**Lambert, Jean** (France). Field: comparative anthropology of monotheist religions. Teacher and researcher, Centre d'Etudes Interdisciplinaires des Faits Religieux of EHESS, Paris and CNRS.

**Le Callennec, Sophie** (France). Field: history of religion in sub-Saharan Africa; Université des Réseaux d'Expression Française (UREF), Paris.

**Legaré, Anne** (Canada). Field: political sociology of modern relations between the state and society. Professor of political science, Université du Québec, Montréal.

**Le Thanh Khoi** (France). Fields: comparative education, social and economic development. Professor Emeritus, University of Paris V (Sorbonne).

**Lootah, Mariam** (United Arab Emirates). Field: contemporary history of the Gulf region. Professor of applied sciences, University of Al Ain, UAE.

**Lugujjo, Eriabu** (Uganda). Field: electrical engineering materials. Consultant in technical and vocational education, and science and technology policy. Professor at Makerere University (Faculty of Technology); former member of the Executive Board of UNESCO; member of the Uganda National Council of Science and Technology.

**MacLeod, Roy** (Australia). Field: social history of science, medicine and technology. Professor of history, University of Sydney.

**Mączak, Antoni** (Poland). Field: modern history of Europe; Professor, Institute of History, University of Warsaw.

**Madelin, Henri, S. J.** (France). Field: political science. Teaches political philosophy and sociology at the Faculté Jésuites de Paris (centre Sèvres) and at the Institut d'Etudes Politiques de Paris (IEP).

**Mahafzah, Ali** (Jordan). Field: contemporary Arab history and thought. Former President of Mu'tah University and Yarmouk University; Professor of history, University of Jordan (Amman).

**Maier, Charles Steven** (United States). Field: twentieth-century Europe and international relations. Leverett Saltonstall Professor of history at Harvard University; member of the American Academy of Arts and Sciences.

**Markova, Ludmila A.** (Russia). Fields: history, historiography of science, philosophy and sociology of science. Researcher, Institute of Philosophy of the Russian Academy of Sciences.

**Mayobre, José Antonio,** *deceased* (Venezuela). Field: international mass media studies. Director of the International Centre for the Study of Communication and Development (CIEDESCO); Professor of mass communication, Universidad Católica Andrés Bello, Caracas, Venezuela.

**M'Bow, Penda** (Senegal). Fields: medieval African history, gender issues and religion. Professor, History Department of the Faculty of Letters and Social Sciences, Cheick Anta Diop University, Dakar; former Minister of Culture of Senegal.

**Moon, Suzanne** (United States). Fields: history of science and technology, history of South-East Asia. Assistant Professor, Colorado School of Mines (US).

**de Moragas, Miquel** (Spain). Fields: communication, technology and social change. Professor of communication sciences; Director of the Institute of Communication, Universitat Autonoma de Barcelona.

**Morange, Michel** (France). Field: biology. Professor at the École Normale Supérieure, Paris, and Université de Paris VI.

**Muhidine, Timour** (Turkey). Fields: contemporary Turkish literature, comparative literature (Europe and Middle East). Reader in Turkish literature at INALCO, Paris; writer and translator.

**Nagy, Zsuzsa L.** (Hungary). Field: twentieth-century Hungarian history. Professor of history at the University of Debrecen with research interests in the two Hungarian revolutions after the First World War, the Paris Peace Conference in 1919; urban history, Budapest; and freemasonry of Europe.

**Nakayama, Shigeru** (Japan). Field: history of science and learning in East Asia. Former Professor, Science Technology and Society Center, Kanagawa University. Professor Emeritus, School of International Business Administration, Kanagawa University.

**Ngoïe-Ngalla, Dominique** (Congo). Fields: pre-colonial history of the Congo and anthropology. Professor, Université de Brazzaville.

**Obeyesekere, Gananath** (Sri Lanka). Fields: social theory, psychoanalytic anthropology and Buddhist history and practice. Emeritus Professor of anthropology, Princeton University (USA).

**Ogunmola, Gabriel B.** (Nigeria). Field: biochemistry. President of the Nigerian Academy of Sciences; Dean of the Postgraduate School of Ibadan University (Nigeria).

**Ory, Pascal** (France). Field: cultural history. Professor, Université de Paris I (Sorbonne).

**Paty, Michel** (France). Field: philosophy, epistemology and history of science. Emeritus Director of research, CNRS; co-founder and former Director of the REHSEIS team of the CNRS and the University of Paris VII (D. Diderot).

**Pereira-Palhinhas, Clarisse** (Congo). Fields: philosophical sciences and linguistics. Faculté des Lettres et Sciences Humaines, Université M. Ngouabi.

**Pestre, Dominique** (France). Field: history of science. Director of Studies, EHESS, Paris; Director of the Centre Alexandre Koyré of the CNRS-EHESS.

**Pols, Hans** (Australia). Fields: history of science, psychology and medicine. Teaches in the History and Philosophy of Science Unit, University of Sydney.

**Raina, Dhruv** (India). Field: social theory of science and technology. Associate Professor in the Department of Social Sciences, Zakir Hussain Centre for Educational Studies of Jawaharlal Nehru University, New Delhi.

**Raj, Kapil** (India). Field: history of science. Professor, Centre Koyré of Ecole des hautes études en sciences sociales (EHESS), Paris.

**Renfrew, Andrew Colin** (United Kingdom). Fields: archaeology and archaeogenetics. Former Professor of archaeology, University of Cambridge; Former Director of the McDonald Institute for Archaeological Research in Cambridge. Supervised many excavations, especially in eastern Macedonia and Greece.

**Romero, Luis Alberto** (Argentina). Field: social and cultural history of contemporary Argentina. Professor, University of Buenos Aires.

**Roncagliolo, Rafael** (Peru). Fields: sociology, communication and journalism. Professor, Universidad Católica del Perú; former President, World Association of Community Radio (AMARC); former Vice-President International Association for Mass Communication Research (IAMCR/AIERI); journalist.

**dos Santos, Theôtonio** (Brazil). Field: political economy. Professor, Universidad Federal Fluminense and coordinator of the UNESCO-UNU Chair/Network on Global Economics and Sustainable Development.

**Sardoni, Claudio** (Italy). Field: macroeconomics and twentieth-century economic analysis. Associate Editor of the *Review of Social Economy* and the *Review of Political Economy*. Professor of economics, Università di Roma 'La Sapienza'.

**Shen, Yilin** (Korea). Field: Korean social sciences. Senior Fellow, Center for Documentation and Information of the Chinese Academy of Social Sciences; former Editor-in-Chief of the *Journal of Social Sciences Abroad*; Vice Editor-in-Chief of *The Republic of Korea Today*; and supervisor of *Koreana*.

**Shouyao, Teng** (China). Field: comparative studies of Western and Eastern philosophy. Head of the Section of Aesthetics; Professor of philosophy, Institute of the Chinese Academy of Social Sciences.

**Siddhartha, Vissid** (India). Field: history of science and technology. Scientific adviser to the Indian Minister of Defence.

**Simonia, Nodari, A.** (Russia). Fields: history of South-East Asia, socio-economic and political problems of developing countries, and national liberation movements. Deputy Director of the Institute of World Economy and International Relations; member of the Russian Academy of Sciences.

**Singer, Peter** (Australia). Fields: philosophy and bioethics. Deputy Director of the Centre for Human Bioethics; Professor of philosophy, Monash University, Melbourne, Victoria.

**Sournia, Jean-Charles** *deceased* (France). Fields: surgery, public health, the history of medicine. Surgeon, member of the French Society of Medical History; Former President of the International Society for the History of Medicine.

**Spence Richards, Pamela** *deceased* (United States). Field: library history. Former Professor of library and information studies, Rutgers University.

**Stykalin, Alexander S.** (Russia). Field: cultural history of Central and South-East Europe. Researcher, Institute of Slavic and Balkan Studies of the Russian Academy of Sciences.

**Svátek, František** (Czech Republic). Field: political history. Senior Researcher and member of the Scientific Council of the Institute for Contemporary History of the Academy of Sciences of the Czech Republic, Prague.

**Thébaud, Françoise** (France). Field: twentieth-century women's studies  Professor of contemporary history at the University of Avignon (France). Founder of the French-language journal, *CLIO, Histoire, Femmes et Sociétés*.

**Thiam, Iba Der** (Senegal). Field: modern and contemporary political history of Africa. Professor of history, University of Cheikh Anta Diop, Dakar.

**Tianshi, Yang** (China). Field: history of Chinese culture and modern China. Professor, Institute of Modern History of the Chinese Academy of Social Sciences. Vice-Chairman and Secretary General of the Association of Modern Chinese Culture.

**Tikhvinsky, Sergeï L.** (Russia). Field: history. Chairman of the National Committee of Historians of the Russian Academy of Sciences, Moscow.

**Tingyang, Zhao** (China). Fields: ontology, epistemology and philosophical logic. Associate Professor, Philosophy Institute of the Chinese Academy of Social Sciences.

**Torstendahl, Rolf** (Sweden). Fields: history and theory of historiography; Emeritus Professor of history, Uppsala University; Professor of history, Mälardalen University.

**Tuduri, Carles** (Spain). Fields: information sciences, communication; development of tourism. Faculty member of the Department of Management and Marketing of the Tourism Industry, Universitat Oberta de Catalunya; Associate Professor for the promotion of tourism, Universitat de les Illes Balears.

**Wagner, Peter** (United Kingdom). Field: history and theory of the social sciences. Currently Professor at the European University Institute (Florence) and has taught at universities in the UK, California, Sweden, Paris and Berlin. Contributor to the UNESCO *World Social Science Report* and author of numerous books.

**Weinberg, Gregorio** (Argentina). Field: history of education and science in Latin America. Honorary Professor of the Faculty of Philosophy and Literature and Doctor Honoris Causa, Universidad de Buenos Aires. Former Director, Centro de Documentación Internacional; former Director, Biblioteca Nacional de la República Argentina; Vice-President, Consejo Nacional de Investigaciones Científicas y Técnicas.

**Wenzhao, Tao** (China). Field: history, Sino-American relations. Research Professor, Institute of American Studies of the Chinese Academy of Social Sciences (CASS); Former Deputy Director and Secretary General, Chinese Association of American Studies.

**Wittrock, Björn** (Sweden). Field: History and sociology of social science. Professor of government, Stockholm University; Director of the Swedish Collegium for Advanced Study in the Social Sciences, Uppsala.

**Wollmann, Hellmut** (Germany). Field: comparative public policy. Professor Emeritus, Humboldt University, Berlin.

**Wurm, Stephen A.** (Australia). Field: linguistics of the Pacific area, East, North and Central Asia, ancient and modern Near East, and Arctic areas. Professor of linguistics, Australian National University; Research Director, former President of the Australian Academy of the Humanities; former President of CIPSH-UNESCO.

**Xin, Ru** (China). Fields: Philosophy and aesthetics. Vice-President, Chinese Academy of Social Sciences; Vice-President, Chinese National Committee for UNESCO.

**Xiushan, Ye Xiushan** (China). Field: Western philosophy and aesthetics. Chairman of the Academic Committee; Professor of philosophy, Institute of the Chinese Academy of Social Sciences.

**Xueyuan, Thian** (China). Field: modern history. Member of the Chinese Academy of Social Sciences, Beijing.

**Yi, Jiang** (China). Field: contemporary Western philosophy. Head of the Section of Contemporary Foreign Philosophy; Associate Professor, Philosophy Institute of the Chinese Academy of Social Sciences.

**Zengjie, Gao** (China). Fields: history of Japanese culture and comparative culture. Professor and Deputy Director, Institute of Japanese Studies of the Chinese Academy of Social Science.

# PREFACE TO VOLUME VII

*Sergeï L. Tikhvinsky*

The seventh and final volume of the *History of the Scientific and Cultural Development of Humanity* is at last available to readers of this unique collection prepared under the supervision of the International Commission constituted by Resolution 4/1.2/6, which was adopted by the General Conference of UNESCO at its 20th session in 1978. Devoted to the twentieth century, this volume was begun along with the other six volumes, but owing to financial difficulties and changes in the staff of the UNESCO Secretariat over the last decade of the century, the preparation of Volume VII (as well as Volume VI, entitled the *Nineteenth Century*) was interrupted for several years. As our readers know, the previous volumes of the *History of Humanity* were published in English by UNESCO and the British imprint Routledge: Volume I, 1994; Volume II, 1996; Volume III, 1997; Volume IV, 2000; Volume V, 1999; and Volume VI, 2004.

The last meeting of the Editorial Board of Volume VII took place in June 1996 at UNESCO Headquarters in Paris. At this meeting, the Board discussed and approved a detailed outline and established a calendar for the completion of the writing and editing processes. Over the following nine years, all contacts between the members of the Editorial Board and the staff of the UNESCO Secretariat were limited to occasional parcels or faxes containing drafts of proposed articles.

Volume VII reflects the great variety of cultures to be found in countries around the world. In spite of increasing interdependence, it can be noted that every nation still strives to maintain its unique cultural identity.

During the above-mentioned meeting of the Editorial Board conducted under the chairmanship of Professor Georges-Henri Dumont from Belgium, President of the International Commission of the History of the Scientific and Cultural Development of Humanity, members of the Board from Argentina, China, India, Russia, Senegal and the United States as well as a representative of the Palestine National Authority expressed their views about the preliminary text of Volume VII as proposed by Professor Everett Mendelsohn from the United States.

The participants of the meeting suggested that authors of the various chapters devoted to the development of science and culture during the century should place them in the context of the period's main political, economic and social processes throughout the world, rather than to set out to undertake 'a political analysis of the century'. Professor Dumont stressed the importance of examining the twentieth century's influence on science and culture, the consequences of the Cold War, the disintegration of the Soviet Union, European unity, ethnic issues, problems of cultural identity following decolonization, and extremist religious movements. Other participants of the discussion emphasized the need to reflect on the growing rift between poor and rich countries and to condemn racism, apartheid and genocide. All participants highlighted the need to explore the process of decolonization and its consequences on the state of education, science and culture in the countries of Africa, Asia and Latin America. They appealed to the authors not to focus only on the negative processes that took place in these countries over the course of the century, but to include the century's positive events and developments as well.

The views and remarks of the members of the Bureau of the International Commission as expressed during that meeting were summarized by the Secretariat and transmitted to the commissioned authors.

In many respects, this final volume of the *History of Humanity* is unique: whereas readers of the preceding volumes generally accept the facts and evaluations presented by the various authors, some readers of Volume VII might disagree with the manner in which certain authors interpret particular events of the twentieth century. This can be explained by the fact that practically all readers of Volume VII will have been born and spent most of their adult life in the twentieth century; indeed, many were not only contemporaries, but also witnesses, and in some cases, actors in the major events of the century. Moreover, they will know about many aspects of the earlier decades of the century through their parents, relatives and friends of elder generations. Therefore many readers will have made their own subjective evaluations of certain events and processes mentioned in this volume. Likewise, as they were educated in the twentieth century, some of the authors were necessarily influenced by the century's events and the

prevailing ideologies and viewpoints. According to a popular adage, 'large objects can only be seen from a distance'. More time is required to develop a multifaceted, objective evaluation of the stretch of the road that humankind has travelled in the twentieth century. When asked how much time people needed to be able to understand the past century, the late-nineteenth-century Russian historian V. Kliuchevsky answered, 'three centuries'.

It is well known that the process of history cannot be cut artificially in a Procrustean manner. So it is with the process of globalization that began several centuries ago and accelerated rapidly in the twentieth century to reach its zenith in the era of cyber communication. In the diverse fields of economy, politics, science and culture, the twentieth century is the continuation of the nineteenth century and witnessed advances in these fields at an ever-accelerating rate.

Similarly, many events that took place in the nineteenth century had their origins in the eighteenth century. For this reason, the authors of Volume VI (from over forty countries) defined the volume's time frame as the period extending from the French Revolution (1789) to the beginning of the First World War (1914).

Many authors in the present volume begin by an incursion into the end of the nineteenth century and the first decade of the twentieth century even though the latter period was already dealt with by some authors of Volume VI. The main division of the *History of Humanity* into centuries is sometimes very arbitary: in China, Korea and Japan and in other East-Asian countries, the system of chronology was based on the rule of a particular emperor or king. In rural areas of these countries, the lunar calendar with its 60-year cycles is still observed. In countries with sizeable Muslim populations, the Islamic calendar began in 622 AD, the year of the Hegira, marking the emigration of the Prophet Mohammed from Mecca to Medina

Before the 1917 Revolution, Russians observed the Julian calendar, which is 13 days behind the more widely observed Gregorian calendar. In 1924, Greece accepted the Gregorian calendar, followed by Turkey in 1927 and Egypt in 1928.

Within the twentieth century, there are also different types of chronological divisions specific not only to various countries but also to distinct branches of science, culture, the arts, sports, etc. The authors contributing to this volume use various means of dating events and processus discussed in their contributions. Some authors consider revolutions to be the principal landmarks of the twentieth century (e.g., the Chinese Revolution of 1911, which overthrew two thousand years of imperial rule and proclaimed a Chinese republic; the revolutions of February and October 1917 in Russia; the Revolution of 1949, which led to the proclamation of the People's Republic of China, etc.). Other authors take as their reference points the First and Second World Wars and the Cold War. Many authors employ such terms as 'atomic era', 'cosmic era', 'era of radio and television', 'jet-propulsion aviation era', 'era of DNA, 'transition and laser era', etc. For former colonies, the chronology of the twentieth century is neatly split into the colonial and post-colonial periods. More than a chronological demarcation, this dividing line reflected a change in historical outlook.

Like previous volumes, Volume VII consists of two parts: a thematic section and a regional section. The chapters of the first section deal with the principal types of transformations observed throughout the world in the twentieth century, the changes in everyday life of different strata and groups of the population (women, young people, elderly people, the disabled, etc.) and evolutions in the fields of education, public health, sports, and in diverse branches of culture, and natural, social and human sciences. In the second section, these subjects are illustrated through examples taken from the regional level and from different countries.

The authors of this volume are scholars from various countries around the world, and they are responsible for the accuracy of the facts contained in their contributions as well as for their evaluation of events and processes.

INTRODUCTION

# THE TWENTIETH CENTURY
# IN WORLD HISTORY

*Georges-Henri Dumont*

When did the twentieth century begin? If we refer strictly to the Gregorian calendar, the response is clear, but as Charles S. Maier demonstrates in the first chapter of this volume, the period from 1901 to 1914 was, in many respects, a continuation of the nineteenth century. In the few industrialized countries of that period, social stratification continued and was intensified by technological progress. The majority of the world's population, which did not have access to the advances of that era, was still engaged in agriculture or traditional production activities. The imperialist world order, which took the form of colonialism in Africa and Asia, was consolidated by this division. The Austro-Hungarian Empire of the Habsburg Monarchy and the Russian Empire of the tsars were multi-ethnic formations that survived in this political context and led to competition, crises and alliances in which colonial rivalries also played a part.

If there is a break with the nineteenth century, it coincides with the First World War, which marks the beginning of what historian Eric J. Hobsbawm calls 'the short twentieth century'.

## THE POST-WAR PERIOD

If we agree that the final battles of the absurd war that lasted from 1914 to 1918 marked the end of the nineteenth century, we must also acknowledge that in 1919, as soon as the treaties of Versailles, Saint-Germain, Trianon, Neuilly and Sèvres had been signed, many of the economic and social problems that were to beset the twentieth century emerged, as did the new century's chosen political orientations. Having bled itself dry for more than four years, resorting to loans after using up all of its reserves to pay for weaponry, Europe forfeited the control of the world's economy that it had exercised for centuries. It was no longer a creditor but a debtor, owing money in particular to the United States, which supplanted it as the world's economic leader.

Treaties are to some extent an opportunity for the victors to settle old scores, and Woodrow Wilson, President of the United States, whose intervention in the war had been decisive, wanted more than the usual diplomatic settlements that had prevailed over the centuries. Wilson proposed bringing the world's moral and spiritual forces together to create a permanent organization that would maintain peace

forever. Although the League of Nations was based on Woodrow Wilson's ideas and his mystical approach to democracy, the United States, paradoxically, was not a member. Léon Bourgeois of France was soon persuaded of the need to create, within the framework of the League of Nations Assembly, an International Committee on Intellectual Cooperation that would study the problems involved in coordinating science libraries, copyright, the preservation of the architectural heritage in Europe and Asia, the organization and role of museums and the collection of major musical compositions and educational films. Albert Einstein, Marie Curie, Henri Bergson, Gonzague de Reynold and Jules Destrée were among the twelve internationally recognized figures who were appointed as members of the committee. Subsequent members included Salvador Madariaga, John Galsworthy, Félix Weingartner, Paul Valéry, Helen Vacaresco and Henri Focillon.

Meanwhile, alas, the first links were being formed in a chain that was to lead to another catastrophe. While in countries whose parliamentary tradition had survived the upheavals of war, power alternated or was shared between socialists and conservatives on a democratic basis, in those countries where poverty had exacerbated the humiliations of defeat or the disillusion of victory and where there had been any kind of revolutionary or nationalist agitation to prepare the ground, the masses were prepared to follow charismatic orators from both the left and the right wings.

In 1917, tsarism had already collapsed in Russia. In the course of the last two months of that year and the first two months of 1918, before the German advance into Russian territory, the All-Russian Congress of Soviets decided to abandon the war. On 23 February 1918, with the German army occupying most of Western Russia and the Ukraine, the new Soviet Government, urged on by Lenin, began forming the Red Army in order to repulse first the German troops and subsequently those of the fourteen states which, alongside the White Army, had joined the military intervention against Russia.

Having emerged victorious from the struggle with the White Army and its allies, Russia was confronted by a drop in agricultural production and an economic depression. Lenin, assisted by L. N. Krassin, the People's Commissar for Trade and Industry, launched the New Economic Policy (NEP), which was beginning to produce its first

*Map 1* **Europe after the First World War**

States created after the First World War

positive results when Lenin was struck down by an attack of hemiplegia. He left the political stage in March 1923 and died in January 1924 (Plate 1).

The fascination of many Western intellectuals with communism, which they regarded as being synonymous with democracy, has been analysed by French historian François Furet.

At first sight, the goals of communism can indeed be mistaken for the goals of democracy, which explains its attraction. They both hope to rid the world of all domination and exploitation. But once Stalin had become secretary-

general of the Communist Party in 1922, he played one supporter against the other, sidelined his opponents and imposed his autocratic rule step by step. Equality was supplanted by party favouritism, fraternity by betrayal and liberty by force.

In Germany, where the Reich had given way to the Weimar Republic, the left wing of the workers' movement and the Spartacists, inspired by the apparent success of the Soviets, tried to stage a revolt. However, they lacked popular support and their leaders, Karl Liebknecht and Rosa Luxemburg (Plate 2), were brutally killed on the

4

orders of the German military establishment. The June 1920 elections revealed that opinion had shifted in favour of the right wing, though not yet to the extreme right. The peace treaties had not been negotiated according to the European tradition of public law. They had been imposed on Germany and were considered by both the army and the people to constitute a *diktat*. Hitler impressed the German masses by his ability to deal with the consequences of the Treaty of Versailles in three years. He presented both communism and capitalism as Jewish initiatives. The spectre of hidden forces — constituted by Jews, Jesuits and Freemasons, who were described as *heimatlos* — led to anti-Semitism and a perversion of Darwinism that gave rise to the idea of a superior race. Six million people — mostly women, children and elderly people — were to be exterminated in the application of this barbarous ideology.

Although the Italians had won the war, they felt they had lost the peace. Widespread discontent with the occupation of factories by workers was exploited by Benito Mussolini, who had founded a new movement, the Fasci di Combattimento, in March 1919. Mussolini abandoned his programme of revolutionary social reforms in favour of nationalism, the glorification of ancient Rome and the exaltation of force and of the leader (or Duce, as Mussolini was to be known), and won over the middle classes, civil servants, tradespeople, farmers and students. When some 50,000 Fascists marched on Rome, they met no resistance, and Mussolini became prime minister.

On the other side of the Atlantic, the Americans were carried away by the prosperity generated by their technical innovations and new production methods, particularly in the automobile industry. Proud of aviator Charles Lindbergh, who had flown non-stop from New York to Paris in May 1927, they were happily buying cars, radios, electrical appliances and furnishings on credit and indulging in a frenzy of speculation on the stock market, which resulted in boosting share prices to levels completely out of proportion with the real value of the firms concerned. In October 1929, the whole system collapsed in a matter of days. In fact, the crash on Wall Street coincided with a downturn of the Kondratieff cycle, conferring on it an aura of unprecedented drama (Plate 3).

The interdependence of the world's economies was soon apparent to all: the crisis promptly became international in scope as it engulfed one country after another. Banks collapsed, factories shut down and raw materials rotted in warehouses. In Brazil, coffee was even used as fuel and burned in the boilers of locomotives. Many countries resorted to protectionism to remedy the situation, restricting imports and raising customs duties.

In the United States, the New Deal introduced by F. D. Roosevelt, elected to the White House on 8 November 1932, led to a recovery assisted by an upturn in the economic cycle, but in Germany the increasing poverty resulting from the depression played into the hands of Hitler's Nazi Party (NSDAP). At the legislative elections held in September 1930, he won 6.4 million votes and 107 seats. Heavy industry supported him by contributing some 2 million marks to his party annually. In the presidential elections of 1932, Hindenburg, still a symbolic figure, won a majority, but Hitler's 13.6 million votes more than doubled the number he had obtained in 1930, and this score was confirmed in that year's legislative elections. On 30 January 1933, Hitler became head of government and established his dictatorship by the ruthless elimination of all opponents and rivals, notably in the so-called 'Night of the Long Knives'.

## A SERIES OF DISASTERS

The series of disasters of the 1930s began in Asia in 1931 with Japan's attack on Manchuria. When the League of Nations condemned this act, Japan responded by leaving the organization in 1933. The West did not want to risk a war in the Far East, and China was compelled to tolerate Japanese occupation of Manchuria, allegedly independent under the rule of P'u-Yi, the last emperor of the Manchu Dynasty, who had been deposed in February 1912.

In October 1933, Germany also left the League of Nations, which it had joined in 1926. The collective security mechanism proposed to the League of Nations by Mr Litvinov, the Soviet Commissar for Foreign Affairs, in 1935 was coming apart, and the fragility of the agreement between France and Great Britain gave the dictators considerable leeway. On 16 March 1935, Hitler violated the Treaty of Versailles by reintroducing compulsory military service and unveiled his plans to reconstitute an army numbering between 500,000 and 600,000 men. France's reaction was to sign a rather vague mutual assistance treaty with the Soviet Union, while Great Britain, without consulting France, authorized Germany to build warships of up to 35 per cent of British tonnage.

In the same year, Mussolini attacked Ethiopia with a view to expanding Italy's territory. Ethiopian Emperor Haile Selassie in turn appealed to the League of Nations, but the resulting economic sanctions against Italy proved to be a fiasco, and the 'empire of the Negus' fell under Italian control.

In March 1936, German troops marched into the demilitarized Rhineland. This was the last opportunity to keep Hitler in check without starting a war. The German troops had orders to withdraw if the French army intervened to prevent the occupation. However, France did not dare make take such action at a time when Italy was protesting against the sanctions decided on by the League of Nations and Britain was negotiating with Hitler. The Rome-Berlin axis was born.

Officers of units stationed in Spanish Morocco mutinied under orders from General Francisco Franco in 1936, and the movement spread to several cities in Spain. The Republican Government opposed the movement, thereby setting the scene for civil war in Europe. Taking advantage of the fact that Great Britain (obsessed by fears that communism might gain a foothold in Spain) and the France of Léon Blum's Popular Front had decided not to intervene, Nazi Germany and Fascist Italy sent equipment and thousands of soldiers to confront the volunteers making up the multinational brigades opposed to Franco. An appalling civil war ensued. 'The firing squads are mowing people down like hay', noted the French aviator and writer Saint-Exupéry. On 26 April 1937, the Luftwaffe bombed the Basque town of Guernica. Two years later, Franco had triumphed and proclaimed himself El Caudillo (leader), joining the Duce and the Führer.

In the meantime, the Nazis had marched into Austria, meeting no resistance. However, more was to come. After

a meeting in Munich on 30 September 1938, Chamberlain and Daladier agreed to the dismantling of Czechoslovakia, naïvely convinced that their policy of appeasement had been successful. That illusion was soon to be dispelled: on 14 March 1939, pro-Nazi Slovakia proclaimed its independence and Bohemia and Moravia were declared a German protectorate. The city of Memel (Klaipeda) and Memelland were seized from Lithuania, and shortly afterwards Mussolini took possession of Albania.

Although it was rather late for the democracies to reverse their policy, they eventually did so by guaranteeing the independence and territorial integrity of Poland, Romania and Greece. In fact, they were incapable of defending any peoples, as Stalin well knew. In the summer of 1939, against a background of continuing negotiations between the USSR and the West, the German-Soviet Pact was concluded. Poland was immediately invaded by the new partnership, although Russia did not join sides in the war until it was attacked by the Nazis on 21 June 1941, which marked the true outbreak of the Second World War. Of a far greater magnitude than the preceding world war, it was to engulf a larger area, bringing with it the horror of systematic genocide exemplified by the Holocaust. Over and above territorial considerations, the very future of civilization was at stake.

In Chapter 2, Charles S. Maier divides the Second World War into four distinct conflicts. The first conflict involved Western Europe. From April to June 1940, Hitler took over Norway, Denmark, the Netherlands, Luxembourg, Belgium and France. Great Britain found itself fighting single-handed on both the Atlantic and the North African fronts. The second conflict, which had a more ideological dimension, began in June 1941 when the Führer decided to invade Russia. The defeat of the German army at Stalingrad on 2 February 1943 was the turning point in this theatre. The third conflict saw Japan overrun the whole of South-East Asia. The Japanese bombing of the American naval base at Pearl Harbor on 7 December 1941 enabled President Roosevelt to surmount the pacifism widely supported by the American public and lead the United States into the war (Plate 4). Until then, the American participation was limited to providing equipment to Great Britain and Russia under the Lend Lease Programme. Despite the Americans' superior weaponry and their contribution to the defeat of Germany in May 1945, the conflict with Japan appeared likely to endure. To curtail it, the United States resorted to atomic weapons in August 1945. The resistance movements in occupied France, Belgium, Norway, Greece, Yugoslavia, Poland and Russia and in South-East Asia were the protagonists of the fourth conflict, which was a key feature of the war despite its lower profile.

A fifth conflict could be added: the battles in North Africa, which continued with the landings in Italy and the collapse of the Fascist dictatorship.

The Second World War also differed from the preceding war by doing away with the dividing line between civilians and combatants. The bombing of Warsaw, Leningrad, Rotterdam, London and Coventry by the Germans, the Allied bombing of Berlin, Hamburg and Dresden, and finally the atomic bombs dropped on Hiroshima and Nagasaki, all targeted civilian populations. If those who died of hunger are included, the civilian death toll probably numbered approximately fifty million.

## ANTI-COLONIALIST MOVEMENTS AND AGITATION BETWEEN THE WARS

While certain European countries were swept by revolutionary fervour from 1920 onwards, Asia and Africa were trying to throw off the yoke of the West. On the one hand, communism encouraged liberation from colonialism, as much out of self-interest as on principle, and on the other hand, the colonized peoples were hearing echoes of Woodrow Wilson's support for self-government. Once released from Ottoman domination by the Allied victories, the Arab States had to contend with British and French ambitions and also the aspirations of the Jews, who had been encouraged by the 1917 Balfour Declaration supporting the establishment of a national home for the Jewish people in Palestine. They found it increasingly difficult to accept the presence of British troops in Baghdad and Jerusalem and of French troops in Beirut.

While Kemal Ataturk repelled the Greeks who had landed in Smyrna, Abd-el Aziz Ibn Saud, the leader of the Muslim Wahhabi sect, deposed Emir Hussein in 1924–1925 to proclaim himself king of what was to become Saudi Arabia. To compensate Hussein's two sons, the British offered the Kingdom of Iraq to Faisal and the Emirate of Transjordan to Abdallah. In the Middle East, tension was thus building up to dangerous levels.

In Persia, theoretically independent (but in fact under the control of the West), Reza Khan, who had commanded a Cossack squadron in Tehran, used a nationalist movement as a basis to seize power and proclaim himself Shah of Iran (Plate 5). In Afghanistan, King Amanullah sought to break loose from the pervasive influence of the British by demonstrating willingness to collaborate with the Soviet Union.

India had sent one thousand soldiers to fight on the battlefields of Europe and borne a considerable proportion of British war costs. In exchange, Indian intellectuals expected their country to be granted autonomy in the form of a dominion status similar to that of Australia and Canada, but the new constitution proposed by Great Britain failed to fulfil these expectations, and the resulting disturbances were severely repressed by the British. Gandhi, a frail-looking man with a gentle yet stubborn temperament who had worked as a lawyer in Bombay, became the spokesperson for the independence movement. He inspired an admiration bordering on awe as he went about preaching passive resistance and civil disobedience and shunned violence. Eventually a violent confrontation occurred between the ancient Indian traditions and British imperialism. Responding to his frequent imprisonments with hunger strikes, the Mahātmā (great soul) exerted an ever-growing fascination on the masses.

Strictly speaking, China had never been colonized, but for a long time, successive Western interventions had severely restricted its independence. There was a puppet government in Beijing, which was dominated by several Chinese military cliques supported by various foreign powers. Sun Yat-sen, and after him Chiang Kai-shek, worked for the unification of China and the abolition of the military cliques. Sun Yat-sen's collaboration with Moscow was decisive. The USSR supported the Kuomintang in its armed struggle against the government in Beijing by supplying arms and dispatching military and political experts. It also organized a modern army, led by Chiang Kai-shek.

In Egypt, nationalist disturbances made Great Britain renounce its protectorate in 1923 and eventually recognize the country's independence, with reservations regarding defence and foreign affairs in particular. The Wafd Party, having won the 1924 elections, continued to pursue its objective of complete freedom from British domination.

Algeria, Tunisia and Morocco were increasingly considered the linchpins of the Muslim community. There was no threat as yet to France's position in Algeria, but in Tunisia the Destour (Constitution) Party was calling for an end to the protectorate and provoking serious incidents. In Morocco, Spain suffered a humiliating defeat at the hands of dissident Rif tribes, and a republic of the confederated Rif tribes was created by a little-known local leader, Abd el-Krim. In 1925, he attacked French Morocco, but the following year the combined French and Spanish forces led by Marshal Pétain forced him to surrender.

From sub-Saharan Africa came as yet no more than faint stirrings: meetings in Kenya organized by Thuku calling for the end of forced labour and the redistribution of land; in the Belgian Congo, the enigmatic utterances of the preacher Kimbangu; and the sudden wave of strikes in Sierra Leone and Gold Coast, formerly part of German Togo.

## THE BURGEONING OF SCIENCE, THE ARTS AND LITERATURE FROM 1918 TO 1940

Whatever else may have happened between the two world wars, it was a period of intense activity in science and produced an abundance of works of art and literature.

Science, especially physics, with the extension of the quantum theory announced by Max Planck in 1900, continued to expand and intensify activity in its fields of investigation. Disciplines became specialized to such an extent that close international collaboration became essential. Einstein would not have been able to formulate his theory of relativity without the experiments of the American Michelson, the formulas of the Dutch physicist Lorentz and the work of the Lithuanian-born mathematician Minkowski. French physicist Louis de Broglie, the initiator of wave mechanics, based his formulation on a combination of quantum theory and Maxwell's electromagnetic theory.

Chemists produced explosives and poison gas but also synthetic medicines and plastic materials, thereby fostering the rapid expansion of photography and cinema, and of insulin, which revolutionized the treatment of diabetes. While physicists proclaimed the existence of the atom, biologists began deciphering the mysteries of the gene.

A new generation of artists and writers emerged from the war with hostility to authority and a desire to break with the traditions of the preceding generations, as evidenced by the work of cubists in France, futurists in Italy, De Stijl in the Netherlands and constructivists and suprematists in Russia, to name the most prominent avant-garde movements. Some members of the literary and artistic avant-garde appropriated dadaism (dating back to 1917), German expressionism and the pre-1914 French literary movement known as unanimisme.

John Willett wrote that surrealism sprang out of dadaism as if making a plea for a revival of the imagination, following the revelation of the unconscious by Sigmund Freud, and for a new emphasis on magic, chance, the irrational, symbols and dreams. In eschewing any rational control, surrealists created a kind of cohesion of the incoherent. Surrealism had a crucial influence on writers such as André Breton, Paul Éluard and Louis Aragon in France, Federico Garcia Lorca in Spain and, to a lesser extent, César Vallejo and Pablo Neruda in Latin America. Transformations of its dream-like images and visions into a form of 'magic realism' can be seen in the paintings of Max Ernst and René Magritte and Salvador Dalí, and in the early films of Luis Buñuel, Jean Cocteau and Jacques Prévert.

While the avant-garde surged forward, many others seeking to re-establish centres of gravity for the spirit and a moral code to help control instinctive forces, focused on contemporary social issues. This was true of the Catholics Paul Claudel, François Mauriac, Georges Bernanos and Paul Valéry, a disciple of Mallarmé, in France. In Italy, Giuseppe Ungaretti adopted a neoclassical approach. Expressing themselves in the German language, Rainer Maria Rilke explored the secret life of the soul, Thomas Mann scrutinized the Hanseatic bourgeoisie, Franz Kafka described the absurd, and Ernst Jünger denounced Nazism in veiled terms, while Bertolt Brecht openly opposed it. In England, scepticism verging on pessimism and a tendency towards sarcasm characterize the work of D. H. Lawrence, James Joyce and George B. Shaw. The exiled American poets T. S. Eliot and Ezra Pound were exceptions. In the United States, writers became aware of their country's different groups and described them in language sometimes far removed from classical English: John Dos Passos with an often brutal energy, Ernest Hemingway with a restrained force, and William Faulkner with refinement.

More than in the nineteenth century, cosmopolitanism encouraged the circulation of both artistic works and their creators. It permeated the works of Paul Morand, André Malraux, Herman Keyserling and Somerset Maugham and enabled the West to discover the Indian poet, Rabindranath Tagore. The École de Paris (the Paris School), which extended its influence as far as the United States, included artists such as Van Dongen (a Dutchman), Picasso (a Spaniard) (Plate 6), Modigliani (an Italian) and Foujita (a Japanese).

In the years following the creation of the Soviet Union, the new regime accepted various predominantly leftist intellectual and artistic tendencies; however, in the early 1930s, the Communist Party outlawed many avant-garde movements and proclaimed so-called 'social realism' as the only officially acceptable artistic doctrine.

Maxim Gorky rallied to the Communist regime, Vladimir Mayakovsky took to singing the praises of the Revolution, and Mikhail Sholokhov, whose writing has sometimes been compared to Tolstoy's, entitled his best-known work *Quiet Flows the Don*. Others, such as Boris Pasternak, were forced underground, and their works would only become known after the Second World War.

Despite the growing reputations of such innovators as Arnold Schönberg and Alban Berg, the avant-garde had little effect on opera, no doubt because the bourgeois audience for this musical genre had no wish to be shocked. Its international repertoire went no further than Richard Strauss or Leos Janacek, and Giacomo Puccini was a staple almost everywhere. But ballet, which had traditionally been associated with opera, was almost completely transformed even before the end of the First World War. In 1917, the

Russian impresario Sergei Diaghilev staged *La Parade* in Paris to music by Eric Satie and with a scenario by Jean Cocteau, scenery and costumes by Pablo Picasso and a programme-introduction by Guillaume Apollinaire. Diaghilev would subsequently collaborate with Igor Stravinsky, Sergei Prokofiev, Georges Auric, Darius Milhaud, Manuel de Falla and Francis Poulenc for musical accompaniment, and Georges Braque, Juan Gris, André Derain and Georges Rouault for set designs and costumes. People were soon flocking to see Diaghilev's ballets, and this brought recognition for the composers and painters involved.

In America, a new style of music known as jazz, which had emerged from the migration of Southern blacks to the cities of the North-East, gained recognition abroad (Plate 7). Welcomed with open arms by the avant-garde because it represented a break with tradition, jazz was seen as a symbol of modernity, and Duke Ellington became a cult figure. The technological developments that led to the establishment of the record industry and radio soon made jazz the universal language of youth culture. Other signs of cosmopolitanism, the Argentine tango and the samba of the carnival of Rio, reigned supreme in dance halls throughout the 1920s.

Before the First World War, cinema had been more a curiosity than an art, but the situation changed during and after the conflict. Charlie Chaplin (Plate 8) was an undisputed genius, and in both Weimar Germany and Soviet Russia avant-garde directors created noteworthy art films. *Battleship Potemkin* by Sergei Eisenstein emerged as a masterpiece of silent film. From the 1930s, the talented populist films of René Clair, Jean Renoir and Marcel Carné stood their ground against the tidal wave from Hollywood, which had secured the collaboration of European exiles such as directors Fritz Lang, Ernst Lubitsch and Billy Wilder and actresses Greta Garbo (Plate 9) and Marlene Dietrich.

As the Second World War approached, India was producing 170 films a year and Japan more than 500, but Hollywood alone, releasing more than 10 films a week, had greater access to world-wide distribution.

Once art nouveau had wound down, the artistic and political avant-garde also set its seal on architecture and the decorative arts for a time. The innovative Bauhaus school for architecture and applied arts founded by Gropius was dissolved in 1933, the same year Hitler took power. Hitler, Stalin and, to a lesser extent, Mussolini opposed all forms of modern art, which they considered decadent. Instead, they encouraged a monumental neoclassical architectural style devoid of originality. In the democracies, on the other hand, innovation was more sought after, thanks to pioneers such as Swiss-born Le Corbusier (Plate 10) and the German-born Mies van der Rohe, who reacted against the extensive use of ornament and sought to set architecture on a rationalist path by favouring clean and simple lines and elegant sobriety.

## HOPES OF A NEW WORLD ORDER

Once the war was over, the full horror of the concentration camps was exposed. In addition to resorting to firing squads, torture and deliberate starvation, Hitler had literally industrialized death. In the concentration camps, the Nazis built gas chambers in which the victims were suffocated by Zyklon B, a gas containing prussic acid. In Auschwitz, the gas chambers could kill 10,000 men, women and children a day. The ovens functioned 24 hours a day, and the ashes and bone fragments that remained were used as agricultural fertilizer.

Realizing that the re-establishment of peace would require quite a different approach from that needed to win the war, all the states that had been directly or remotely involved in the Allied effort proclaimed their determination to save succeeding generations from the scourge of war, which twice in our lifetime has brought untold sorrow to mankind. The United Nations founding conference was held in San Francisco from 25 April to 30 June 1945. Its Member States undertook to take collective action to maintain peace and friendly relations, based on the principle of equal rights of peoples and their right to self-determination, to deal with economic and social, intellectual and humanitarian international problems in a manner respectful of human rights and fundamental freedoms for all, without distinction of race, sex, language or religion (Plate 11).

Although the United States had not joined the League of Nations, it was the driving force behind the United Nations, which had at its disposal financial and technical resources vastly superior to those of the League of Nations, and a network of specialized agencies. UNESCO was founded to deal with education, science and culture, while the International Labour Organization and the World Health Organization focus on work- and health-related issues, respectively. Other specialized agencies included the Food and Agriculture Organization, the International Bank for Reconstruction and Development, the International Monetary Fund, the International Civil Aviation Organization, the World Meteorological Organization, the Universal Postal Union and the International Telecommunications Union. Subsequently, other institutions would be set up as needed, for example the United Nations Development Programme and the United Nations Environment Programme.

The twenty Member States that founded UNESCO in London on 16 November 1945 wished to resume the work of the defunct International Committee on Intellectual Cooperation in a considerably broadened scope. Meeting amidst the smoking ruins of the British capital, they asserted that, in the words of American poet Archibald MacLeish, 'it is in the minds of men that the defences of peace must be constructed'. In the second half of the twentieth century, UNESCO carried out a considerable number of tasks: promoting the right to education; effectively contributing to the rescue, safeguarding and enhancement of humanity's cultural and natural heritage; providing support for artistic creativity, so often stifled and endangered by the new technological and economic environment; mobilizing political leaders to increase and share scientific knowledge; promoting the free flow of words and images; and attempting to reduce the flagrant imbalance in access to information and means of communication available to industrialized and developing countries.

More vulnerable than the specialized agencies, the United Nations General Assembly and Security Council often proved incapable of taking positions. At the beginning of 1947, fighting was reported in China, Greece, Palestine, India, Indonesia and Indo-China, and the USSR pursued its eastern European expansion, which Stalin considered essential to the country's security.

Meeting in Yalta, Roosevelt, Churchill and Stalin divided Europe along the front lines reached by Allied forces. Neither Roosevelt nor Churchill had wanted this division, but the two leaders resigned themselves to the *fait accompli*. The countries of Central and Eastern Europe were subsequently plunged into communism: Poland and Czechoslovakia after unsuccessful attempts to save a parliamentary regime, and Romania, Bulgaria and Albania by communist minorities supported by the Soviet Union. Tito's Yugoslavia was the only country to opt spontaneously for a people's democracy, thus obtaining a degree of freedom from the Kremlin.

On 10 December 1948, the United Nations General Assembly adopted the Universal Declaration of Human Rights. Forty-eight of the then Member States voted in favour, none against and eight abstained. The text's principal author, Nobel Prize winner Professor Cachin, once drew a distinction between the declaration proper and the implementing measures, which he considered more important and less carefully elaborated. Unfortunately this assessment remains relevant at the beginning of the twenty-first century, notwithstanding the development of new generations of rights: economic, social and cultural rights, the right to education, development and humanitarian assistance, the rights of the child, and so on.

## THE COLD WAR

Germany was split in two by the Potsdam Conference (1945), but Berlin had a special status, occupied by the Soviets in the east, the British in the north-west, the Americans in the south and the French in the south-west. The sectors administered by the Americans and British promptly became a bizone, the nucleus of the future federal state of West Germany.

Communist ideology had not just penetrated Central and Eastern Europe. Civil war was raging in Greece, and had it not been for the presence of 40,000 British soldiers, the country might have fallen to the guerrillas (*andartes*) of Markos Vafiadis, making Turkey an indefensible outpost in an ocean of communism. Of even greater concern to the President of the United States, Harry Truman, was the considerable threat of the communist parties in France and, especially, Italy. Truman considered it necessary to counter the risk of economic, social and political disintegration by supporting Europe with America's surplus resources. The Marshall Plan was approved by the United States Congress on 2 April 1948 and administered by the sixteen members of the Organisation for European Economic Co-operation (OEEC).

Stalin's response to the introduction of the new German mark and the creation of the OEEC and the bizone was to block land access to West Berlin. Two million Berliners might have starved or frozen to death if the Americans had not airlifted supplies of food and coal. The blockade was finally lifted on 12 May 1949. One month earlier, the first steps towards the American policy of containment had been followed by the signing of the North Atlantic Treaty on 4 April, which involved the United States in the Western defence system (Plate 12).

A world divided into two camps, each armed with atomic weapons, was entering the period of the Cold War, and the first confrontation occurred in the Far East. Despite receiving American aid worth over \$2.2 billion between 1945 and 1949, the armies of the discredited Chinese government of Chiang Kai-shek were beaten by the troops of communist leader Mao Zedong. The struggle came to an end on 1 October 1949, when Mao proclaimed the establishment of the People's Republic of China, and Chiang Kai-shek took refuge in Taiwan, an island militarized by the Americans.

No sooner had the communists triumphantly concluded the civil war in China than another conflict broke out. On 25 June 1950, the armies of the Democratic People's Republic of Korea (known as North Korea) crossed the 38th parallel, which, by virtue of the Tehran Conference (1943), separated it from its rival to the south, the conservative Republic of Korea. The latter, led by Syngman Rhee, was recognized by Washington, while North Korea, led by Kim Il-Sung, was recognized by the USSR.

The matter was immediately submitted to the United Nations Security Council, which the USSR was boycotting in protest against the presence of a representative of Chiang Kai-shek's Nationalist Chinese Government. As there was no risk of the notorious veto being applied, the Security Council decided to oppose the aggressor by force and requested that the United States appoint a commander to the intervention force that would fight under the United Nations flag.

Many West European contingents rallied to the United Nations' call, but there was no doubt that operations were financed and directed by the United States. Initially, the intervention forces drove the invaders back to the border with Manchuria, but the unexpected mass intervention of the Chinese communists, supported by the USSR, changed the situation. It took the skilful strategy of General MacArthur to give the United Nations troops the advantage once again, and the Chinese-North Korean forces were driven back beyond the 38th parallel. General MacArthur, who publicly favoured an all-or-nothing approach, hoped to continue fighting until he reached Manchuria. Refusing to take responsibility for unleashing a global conflict, President Truman overruled General MacArthur and recalled him.

When the Chinese and North Koreans realized they could not win, they agreed to negotiate, and an armistice reinstating the status quo before the outbreak of the conflict was signed in Panmunjom on 27 July 1953.

The Cold War had been intensified by the Korean War. The United States sought allies, urging Japan to reconstitute a defence force, and in 1954 the Americans sponsored the creation of the Southeast Asia Treaty Organization. In the same year, the United States signed a pact with the Nationalist Chinese government of Taiwan concerning the island's protection. In 1955, the United States supported the creation of the Baghdad Pact (later to become the Central Treaty Organization — CENTO) signed by Great Britain, Turkey, Iran, Iraq and Pakistan and designed to counter Soviet expansion in the region.

The USSR possessed the atomic bomb as early as 1949, and the strategy of Nikita Khrushchev, Stalin's successor from 1953 to 1964, took account of the atomic factor, focusing on the development of intercontinental ballistic missiles. On 14 May 1955, Moscow responded to the admission of West Germany to NATO by creating the Warsaw Pact, which brought seven Eastern European countries under a unified command controlled by Moscow.

In the United States, President John F. Kennedy and his Secretary of State Robert McNamara favoured the doctrine of flexible response, making it possible to intervene in all sorts of conflicts without immediately resorting to nuclear weapons. One of President Kennedy's first crises erupted in Cuba. In 1959, Fidel Castro had seized power on the island, putting an end to the corrupt and bloody dictatorship of Sergeant Batista. The new regime's left-wing tendencies were of concern to major American industrial interests that were deeply committed in Latin America and very influential in the White House. In July 1960, President Eisenhower, hoping to eradicate the communist experiment at an early stage, reduced to 700,000 tonnes the import quota for Cuban sugar. As might have been expected, the USSR bought the sugar Washington had refused, supplied Fidel Castro with oil and offered to place rockets at his disposal. This support from the USSR reinforced Cuba's revolutionary tendencies, which spread throughout Latin America, where the immense poverty of the masses made communism particularly appealing.

President Kennedy had refused to intervene when anti-Castro forces, backed by the CIA, attempted to invade Cuba in 1961, but when he became convinced in the following year that the Soviets were building missile launching ramps in Cuba and dispatching nuclear weaponry to the island, he asked the Senate for authorization to recall 150,000 reservists and took a series of military measures that clearly demonstrated his refusal to yield to the Soviets. On 22 October 1962, President Kennedy presented Nikita Khrushchev with an ultimatum. Khrushchev finally agreed to repatriate the rockets and dismantle the bases, whose existence Fidel Castro had consistently denied, in exchange for the dismantling of American missiles along the Turkish-Soviet border.

## DECOLONIZATION

Already underway before the advent of the Cold War, the process of decolonization, which led to the end of the world's empires, was undoubtedly one of the major events of the twentieth century. It began in Asia for a variety of reasons, the most important of which, as regards Indo-China and Indonesia, was the fanning of hatred towards Europeans by the Japanese army in the countries that it had occupied, then, after the capitulation, the arming of nationalist movements in the hope that they would oppose the return of the colonizers.

The United Kingdom had been weakened by the war, and this accelerated decolonization in India, but complications soon arose from the Muslim League's determination to secure the establishment of an independent Muslim State. There were riots and massacres, notably in Bengal and Calcutta. Despite Gandhi's efforts and prestige, he was unable to prevent partition. In August 1947, after a round-table meeting, Lord Mountbatten announced the creation of two states, India and Pakistan. As soon as the viceroy and British troops had left, in January 1948, disorder ensued. Gandhi was assassinated by a supporter of the caste system, and tension between the two new countries continued, with both laying claim to Kashmir. The British colonial monolith had been divided into five independent states: India, Pakistan, Sri Lanka (Ceylon), Bangladesh and, after 1947, Burma, which had been occupied by the Japanese.

During the war, Indonesians like Sukarno had collaborated with the Japanese. Rejecting the return of the Dutch, they sought independence. The Dutch Government agreed to a kind of Indonesian Commonwealth in the framework of a Dutch-Indonesian Union, but to no avail. The Dutch then tried to force the nationalists into submission. India and Australia appealed to the United Nations Security Council, which ordered a 'ceasefire'. Fighting nevertheless continued, but the Dutch had only limited military resources at their disposal. On 27 December 1949, they finally recognized the independence of the Republic of Indonesia.

In Indochina, too, the departure of the Japanese triggered a nationalist groundswell of opposition to the colonial power. Ho Chi Minh, the leader of the Viet Minh Communist Party, took over Government House in Hanoi and proclaimed Vietnamese independence. Bao Dai, the emperor of Annam, was obliged to abdicate. The French played a double game, recognizing the Republic of Viet Nam as a free state belonging to the French Union, but at the same time seeking to make Cochinchina, in the south, a separate autonomous republic. The government of the latter was entrusted to Bao Dai and recognized by London and Washington, while Ho Chi Minh's government was recognized by Moscow and Beijing. The ensuing First Indochina War lasted six and a half years, and France sacrificed 92,000 dead, 114,000 wounded and several billion dollars before agreeing to a ceasefire at the Geneva conference. Viet Nam was divided into two along the 17th parallel: to the north, the People's Republic of Viet Nam, and to the south an independent state with Cambodia and Laos lying to the west.

The Americans were slow to realize that the First Indochina War was not simply a colonial war, and eventually discovered at great cost that the expulsion of the French had not improved the situation in South-East Asia in the slightest.

The Bandung Conference, which took place in Indonesia in April 1955, marked a turning point in the history of decolonization. For the first time, Africans and Asians from independent developing countries met to publicly proclaim their unwillingness to be dominated by the great Western powers. The conference was attended by delegates from 29 Asian and African countries, representing one-half of the world's population. They unanimously condemned racism and colonialism, denounced the dangers of nuclear weapons and called for peace. They refused to align themselves either with Moscow or with Washington, a position that would prove untenable.

In Bandung, Nehru had affirmed Asia's wish to assist Africa. The British Government had long ago decided on the progressive emancipation of its African colonies with representative nationalist movements. As early as 1954, it had abrogated the rights conferred by treaty on the British in Egypt, thereby leading to the independence of the Sudan, until then administered jointly by Egypt and Britain. In the wake of these events came the decolonization of the Gold Coast, where Kwame Nkrumah had subjugated the population. On 6 March 1957, in the presence of the Duchess of Kent, Ghana's independence was solemnly proclaimed in Accra. Nkrumah remained in power until 1966, when a military junta overthrew him.

After discussions held at three round tables and marked by a visit from Queen Elizabeth II, Nigeria gained

independence in 1960, but civil peace was shattered seven years later by the war that erupted following the secession of Biafra.

From 1960, decolonization gathered pace. In that year, the British relinquished British Somaliland, which merged with the formerly Italian Somalia. In 1961, Sierra Leone and Tanganyika gained independence. Uganda followed suit in 1962, and Zanzibar in 1963. The situation in Kenya was more complex: London's efforts to seek conciliation led first to a multi-racial government and then to independence. In 1964, Nyasaland became Malawi and Northern Rhodesia Zambia. In the same year, Tanganyika and Zanzibar merged to form Tanzania.

After the Second World War, France, like Great Britain, recognized the inevitability of the emancipation of its sub-Saharan African colonies. For a long time, it believed that the process could take place within the framework of a policy of assimilation 'into the life and institutions of the French community'. In 1956, the French Government passed a law (Loi-Cadre Deferre) providing for representative institutions in the twelve West African territories under its authority and in Madagascar. The initiative failed to satisfy the demands of a majority of African leaders, who proclaimed during a meeting held in Bamako, from 25 to 30 September 1957, that 'the independence of peoples is an inalienable right enabling them to exercise the attributes of their sovereignty in the interests of the masses'. Realizing the shortcomings of the Loi-Cadre Deferre, General de Gaulle, who was recalled to power in March 1958, declared, in a speech given on 24 August 1958 in the sports stadium of Brazzaville, 'Whoever wants independence can take it. The metropole will not seek to prevent it'. A referendum ensued, and only Guinea chose independence, the other countries preferring autonomy within the French Community, which entitled them to receive economic and financial assistance from the metropole. However, the referendum was ambiguous, and autonomy was accepted only as a step on the path to independence, which was rapidly obtained by Congo-Brazzaville, the Ivory Coast, Dahomey, Upper Volta, Madagascar, Mali, Mauritania, Niger, the Central African Republic, Senegal and Chad. Some of these new states were fortunate enough to be led by outstanding figures such as Félix Houphouët-Boigny of the Ivory Coast and especially Léopold S. Senghor of Senegal, who extolled the cultural concept of 'negritude' in his writings.

French policy in North Africa differed from that carried out in sub-Saharan Africa. There were 200,000 Europeans in Tunisia, 300,000 in Morocco and 1 million in Algeria. Whereas France resigned itself fairly promptly to the independence of Tunisia and Morocco, it wished to retain its hold on Algeria. From 1957 to 1960, General R. Salan and his army conducted a war in which the use of torture and collective repression outraged the Catholic Church and many French intellectuals. The Algerian War destabilized France and its army, which was shaken by a failed generals' putsch. General de Gaulle had returned to power thanks to the insurrection of French extremists in Algeria, and paradoxically he ended the conflict by subduing the extremists and granting independence to Algeria in the Evian Agreements of 2 July 1962.

In the meantime, the Belgian Congo was granted independence rather precipitately after a round-table meeting in 1960, but this was followed by a series of coups

d'état, the attempted secession of Katanga, the assassination of Patrice Lumumba (Plate 13), and, the rise to power of the dictatorial General Mobutu.

A series of delayed decolonizations ensued beginning in 1980 with Southern Rhodesia, thereafter known as Zimbabwe, as a result of the unilateral declaration by Ian Smith establishing an independent regime controlled by the white settlers. Decolonization occurred in Guinea-Bissau and subsequently in Mozambique, the Cape Verde Islands and Angola thanks to Portugal's 'Carnation Revolution', which unseated President Caetano, the successor of Salazar. In 1977, Djibouti, the former territory of the Afars and Issas, gained independence. The long struggle against the racist regime in South Africa led to the abolition of apartheid in 1990, and eventually to multiracial elections, from which the former political prisoner Nelson R. Mandela emerged as the country's first black president (Plate 14).

The decolonization process examined by Professors N. A. Simonia and I. D. Thiam in Chapters 4, 5, 6 and 7 of this volume completely transformed the world political map. The number of independent states in Asia increased five-fold, while those in Africa rose from one (in 1939) to nearly fifty. Decolonization, however, did not solve all the problems of the young states. The new Africa, facing formidable difficulties, neglected agricultural development to focus on industrial technologies, most often implanted by multinational firms. This was one of the forms of neo-colonialism that confronted the countries of the Third World with unequal terms of trade. Another form of neo-colonialism resulted from exponentially increasing debt, aggravated by the International Monetary Fund (IMF), which forced governments to impose draconian budgetary restrictions on their people, with dire effects: unemployment, collapse of public services, poor infrastructure maintenance, price increases, currency devaluation, and deteriorating health and education services. A source of rivalry between East and West until the collapse of the USSR, Africa also suffered from Balkanization, as the frontiers between its states were those of the former colonies and seldom those of the different ethnic groups. Some 70 coups d'état ensued, not to mention ferocious outbreaks of genocide in the Great Lakes region.

## THE EXPLOSIVE SITUATION IN THE MIDDLE EAST

The Afro-Asian neutralist movement initiated by the Bandung Conference was reinforced via the Islamic Jakarta-Tangiers axis, which was based in the Near East. Referring to this region, Lenin had declared 'Whoever holds sway there will be master of the world'.

Great Britain had raised the thorny problem of the 'Jewish national home', but being unable to reach a solution to the satisfaction of both Arabs and Jews, the issue was passed on to the United Nations, which, in November 1947, recommended the division of Palestine into a Jewish State and an Arab State. Jerusalem was to be granted an international status. The Zionists were quick to react: on 14 May 1948, the day after the British mandate in Palestine ended, Israel unilaterally proclaimed its independence under the presidency of Chaim Weizmann. The Arabs immediately took up arms but, most unexpectedly, the young Israeli army fought them off and went on to annex the Negev and

West Galilee. Count Bernadotte, dispatched by the United Nations as mediator, was assassinated by Jewish terrorists.

While the states of the Arab League and Israel continued to engage in both covert and open warfare, Great Britain, together with France, the United States and Turkey, requested Egypt to participate in the defence of the Middle East as regional state and co-guarantor. This proposal, which ultimately led to the Baghdad Pact, was categorically rejected by the Egyptians, who also demanded the immediate and total evacuation of British citizens present on their soil.

On 23 July 1952, a military coup led by General Mohammed Neguib led to King Farouk's abdication and the proclamation of an Egyptian republic. In 1954, the same year, Syrian President Adib Shishakli was ousted by a military revolt, and General Neguib was relieved of all his responsibilities and replaced by Colonel Gamal Abdel Nasser. On 26 July 1956, after the United States had withdrawn its offer of loans to build a high dam on the Nile at Aswan, Nasser announced the nationalization of the Franco-British Suez Canal Company. 'More than half of Britain's annual imports of oil came through the canal', recalled the then British Minister of Foreign Affairs, Anthony Eden, in his memoirs. France had not forgotten the considerable support, both moral and material, the Algerian insurrection had received from Nasser's Egypt, and Israel, for its part, was more than willing to take the opportunity to expand. On 26 October 1956, it attacked Egyptian positions in the Sinai Peninsula. Two days later, a Franco-British air force went into action in the canal zone, and parachutists occupied Port Said. The matter was brought before the United Nations by the USSR, which had just crushed a revolution in Hungary and was free to intervene elsewhere, and the United States, in the midst of presidential elections, felt that the adventure was likely to exacerbate feelings in the Arab countries and throw Egypt into the arms of the Soviets. The United Nations General Assembly condemned France, the United Kingdom and Israel, ordered the withdrawal of their forces and decided to send in the United Nations' own forces, the 'blue helmets'. The Franco-British-Israeli forces resigned themselves to withdraw from Egypt, thereby ending a colonial war without resolving the Middle East conflict.

After the Franco-British-Israeli diplomatic defeat in the Suez Crisis, Colonel Nasser assumed the role of the uncontested leader of Arab nationalism and hoped to realize the long-cherished dream of pan-Arab unity. Although he failed in Jordan, where King Hussein, after dissolving his parliament for their pro-Nasser leanings, was rewarded by America, Nasser succeeded in Syria, which united with Egypt to form the United Arab Republic from 1958 to 1961, and in Iraq, where General Qasim overthrew the monarchy.

In 1967, when Nasser barred access to the Gulf of Aqaba to ships flying the Israeli flag, Israel launched a preventive war against Egypt, Syria and Jordan. In six days, Israeli troops took the Gaza Strip, Sinai, the West Bank and the Golan Heights. Once again, the United Nations intervened. Security Council Resolution 242 recognized Israel de facto but required it to withdraw from the territories conquered during the Six Day War. However, the resolution did nothing to improve the immediate situation.

In 1969, Yasser Arafat took control of the Palestine Liberation Organization (PLO) and opted for an ambiguous two-pronged strategy, which consisted of encouraging guerrilla operations while using diplomatic means to promote his position at the international level.

The Palestinian resistance had established itself in Jordan, and in September 1970, King Hussein organized a comprehensive crackdown, forcing 5,000 members of the PLO to leave Jordan for Lebanon or Syria. This prompted certain factions to resort to international terrorism. At the Olympic Games in Munich in 1972, a Palestinian commando – named Black September in reference to the crackdown in Jordan – massacred twelve Israeli athletes.

In 1970, Anwar al Sadat succeeded Colonel Nasser. Two years later, applying the doctrine of non-alignment supported by Tito in Yugoslavia and Nehru in India, Sadat demanded and obtained the withdrawal of the 20,000 Soviet military advisers previously invited to Egypt by Nasser. On 6 October 1973, the day of the Jewish feast of Yom Kippur, the Egyptian army crossed the Suez Canal, and the Syrian army attacked the Golan Heights. Taken by surprise, the Israeli forces were nearly defeated for the first time. During the same period, the representatives of ten Arab states, meeting in Kuwait, used oil as a weapon, doubling the price of the barrel on two separate occasions and exacerbating the crisis already affecting the industrialized world. In the face of this renewal of hostilities, the United Nations Security Council adopted Resolution 338, which provided for a ceasefire, the application of Resolution 242 and negotiations with a view to the establishment of a just and lasting peace in the Middle East.

The Cold War formed the backdrop to this series of conflicts in the Middle East. In order to prevent the USSR from bringing its influence to bear in the region, United States President Nixon instructed his secretary of state, Henry Kissinger, to persuade Israel – the Yom Kippur War having turned to its advantage – to cease hostilities, and Egypt to accept a compromise. In 1977, the United States and Egypt agreed to ask the Israeli Prime Minister Menachem Begin to engage in the negotiations that led to the Camp David Accords, signed in Washington in 1978 under the presidency of Jimmy Carter (Plate 15). According to these agreements, Egypt recognized the existence of Israel, in exchange for Israel's evacuation of the Sinai Peninsula.

If President Carter thought he had laid the foundations for a comprehensive solution to the problems of the Middle East, he was soon to be disappointed. Syria and Iraq called Egypt to task for concluding a 'separate peace' and in 1981 Anwar al Sadat was assassinated by Islamic fundamentalist army officers.

The Camp David Accords had not provided for any solution to the problems of Palestinians living in the territories still occupied by Israel or in refugee camps in Jordan, Lebanon and Syria. It was, in fact, from its bases in Lebanon that the PLO launched its numerous raids on Israel. Intent on putting an end to the raids, Israel invaded Lebanon in June 1982 on the orders of Defence Minister Ariel Sharon, and the Phalangist Christian militia perpetrated massacres in the Sabra and Chatila refugee camps. Under pressure from outraged international opinion, Israel concluded a peace treaty with Lebanon in 1983 and agreed to withdraw its forces, except in South Lebanon, an area still divided among various factions. Syria was standing by.

In Palestine, too, clans and factions were co-existing uneasily when not in open conflict. The PLO opted for moderation and accepted United Nations Resolutions 242 and 338, but many

radicals rejected this approach and joined Al Fatah. Nineteen eighty-seven marked the beginning of the first intifada or Palestinian 'uprising' in Gaza and the West Bank, but the PLO managed to keep the demonstrators under control (Plate 16). At a meeting in Algiers in November 1988, the organization recognized the existence of two states – one Jewish and one Arab – which earned it the recognition of the United States.

To add to the confusion in the Middle East, in 1990 Saddam Hussein's Iraq, which was embroiled in war with Iran during most of the 1980s, invaded Kuwait and bombarded the State of Israel with Scud missiles, posing as the champion of Arab identity and the Arab cause. Israel's refusal to retaliate foiled Hussein's hopes for the formation of an Arab league. The Iraqis were beaten by an international coalition endorsed by the Security Council and directed by the United States, without the participation of Russia. Not wishing to exceed their United Nations' mandate (the liberation of Kuwait), the coalition troops did not march on Baghdad, nor did they support a Shiite uprising, which the Americans had encouraged in the hopes of overthrowing Saddam Hussein's dictatorial regime.

For a while, the Gulf War positively affected the situation in the Middle East. A meeting in Madrid, sponsored by the United States and Russia, brought Israel, Egypt, Syria and Lebanon to the same negotiating table. PLO delegates also took part in discussions as members of the Jordano-Palestinian delegation. The letter of invitation to the Madrid Conference provided for a first phase of bilateral negotiations to be followed by a phase of multilateral negotiations dealing with regional issues, such as arms control, regional security, water, the refugee question, the environment, economic development and other questions of general interest. It was an admirable initiative that remains relevant at the beginning of the twenty-first century.

The first steps were encouraging. In August 1993, Israeli Foreign Minister Shimon Peres met representatives of the PLO secretly in Oslo and together they prepared the groundwork for an agreement on Palestinian autonomy. In September, a declaration on Palestinian autonomy was signed in Washington. The PLO recognized the legitimacy of the State of Israel, while the Israelis accepted the PLO as negotiating partner and declared their willingness to militarily withdraw from the Gaza Strip and Jericho. In September 1995, the Taba Agreement – known as Oslo II – expanded Palestinian autonomy, but the signing of the agreements failed to put an end to the terrorist attacks and suicide missions of Palestinian kamikazes or to the installation of more Jewish settlements. On both sides, fanaticism overruled wiser counsel. In November 1995, Prime Minister Yitzhak Rabin was assassinated by a radical Israeli, and in July 2000 Prime Minister Ehud Barak and Yasser Arafat dug in their heels at Camp David, despite President Bill Clinton's desire for an agreement. Radicals in both camps welcomed the failure of Camp David.

On 28 September of the same year, Ariel Sharon, the leader of the opposition and future prime minister, provoked the indignation of Muslims by paying a visit to the Haram al-Sharif, an Islamic holy place in Jerusalem. Whether deliberate or unintentional, Sharon's defiant gesture triggered off the second intifada, which was more violent than the first and intensified as the Israelis took increasingly repressive action against it. Murderous suicide missions were followed

by no less murderous reprisals. At the end of the twentieth century, few people still talked of negotiations.

## THE COLLAPSE OF THE USSR

The Gulf War had made it abundantly clear that there was only one remaining superpower: the United States. Before the America of President George W. Bush attained a solid potential for imperialism, President Reagan implemented a rearmament policy (totalling 7 percent of the country's GNP) that forced the USSR into military expenditure beyond the capacities of the Soviet economy despite the desire of Soviet leader Leonid Brezhnev to remain competitive with the United States in this field. When Mikhail Gorbachev came to power in March 1985, the situation changed. Hoping to liberalize the communist economy, the new Kremlin leader set out to implement a transitional policy somewhere between outright capitalism and orthodox socialism. Alongside economic *perestroika* ('reconstruction'), his policy of *glasnost* ('openness') was intended to introduce transparency in political and social issues. Press censorship was abolished, and the Supreme Soviet publicly condemned the Stalinist era. In the realm of foreign policy, Mikhail Gorbachev put an end to the Cold War by initiating the talks that led to the 1987 signature in Washington of a treaty in which Americans and Soviets agreed not only to a general arms limitation but to the progressive destruction of their nuclear weapons.

*Perestroika* and *glasnost* spread to the satellite countries in Eastern Europe like a tidal wave. In Poland, where native son Pope John Paul II wielded considerable influence, agitation spearheaded by Lech Walesa's Solidarnosc movement had gained so much popularity between 1981 and 1988 that President Jaruzelski was obliged to agree to free elections. Solidarnosc's landslide victory in 1989 marked the beginning of the end of communist domination. Hungary followed suit by opening its border with Austria, and thousands of East Germans rushed through the breach thus opened to immigrate to West Germany. Erich Honecker was forced to step down as president and, on 9 November 1989, his successor, Egor Krentz, decided to hold free elections. The same evening a jubilant crowd began dismantling the quintessential symbol of the Cold War, the Berlin Wall (Plate 17). Less than a year later, the two Germanies were united. The communist regimes in Bulgaria and Czechoslovakia were the next to be overthrown, but that of Romania ended in a bloodbath. Dictator Nicolae Ceaușescu and his wife were arrested and executed with no semblance of legality. In August 1991, Gorbachev granted independence to the three Baltic States: Lithuania, Latvia and Estonia.

The revolution took an ugly turn in federal Yugoslavia under the Serb Slobodan Milosevic. In the spring of 1990, Slovenia, Croatia, and Bosnia and Herzegovina had announced their intention to leave the federation. Slovenia secured its independence after a ten-day battle with the federal army, but the Serbs managed to occupy a third of the territory of Croatia, which had not yet organized its defence, before a provisional ceasefire was imposed by the United Nations. Fighting broke out again, and it was not until 1995 that the Croats gained the upper hand. Militias on both sides engaged in 'ethnic cleansing'.

Outbreaks of ethnic cleansing increased during the battle for the independence of Bosnia and Herzegovina.

The United Nations and subsequently NATO intervened. In the American city of Dayton, Ohio, in 1995, Serbs, Croats and Muslims agreed on a division between a Croat-Muslim federation, including the war-torn city of Sarajevo, and the Serbian Republic (Republika Srpska). The conflict's death toll numbered 200,000, and more than 2 million men, women and children were forced into exile.

In Kosovo, an integral part of Serbia, Milosevic had arrested the leaders of the Albanian majority in 1989, and put the Serbian minority in control of the province. The Democratic League of Kosovo responded by organizing unofficial elections, which brought Ibrahim Rugova to power in a parallel government. In early 1997, the Albanian resistance rallied behind the Kosovo Liberation Army, and the scene was set for civil war. Serbian politicians and paramilitaries tracked down rebels and carried out massacres in villages suspected of having harboured them. NATO made its position clear by organizing aerial manoeuvres above Albania, thus helping the United Nations to persuade Milosevic and the Kosovan Muslims to agree to a ceasefire on 13 October 1998. The 1,380 observers sent to Kosovo by the Organization for Security and Cooperation in Europe (OSCE) quickly discovered a mass grave crammed with the bodies of the executed Albanian Kosovans. International opinion was as outraged as it had been by the Serbian-led genocides in Bosnia and Herzegovina. Milosevic responded to the NATO delegates who had come to Belgrade to protest by expelling the OSCE observers from Kosovo. The talks held in Rambouillet (France) in February 1999 ended in complete failure. Without UN approval, NATO bombed Serbian positions in Kosovo and deployed troops. Entrusted with the difficult task of supervising the reconstruction of the province and maintaining order, NATO forces have remained in the region to the present day, but the situation in the Balkans continues to be explosive.

## EUROPE'S PROGRESS TOWARDS UNITY

The states of Western Europe assumed some important tasks in the context of the efforts of NATO and the United Nations to deal with the murderous imbroglio in Bosnia and Herzegovina and in Kosovo, but they were bystanders in the diplomatic process, leaving the United States in sole charge of the diplomatic manoeuvring and decision-making. This situation demonstrated that the long march towards European unity had not yet achieved the objective of a common foreign policy.

The starting point was the creation of the European Coal and Steel Community (ECSC) in 1951 by France, Italy, Germany and the Benelux countries (Netherlands, Belgium and Luxembourg). The ECSC was founded with the aim of sowing the seeds of a broader and more integrated community, but the plan for a European Defence Community had been rejected by the National Assembly in France, leading to some consternation followed by a period of reflection. In 1955, the foreign ministers of the so-called 'Six' met in the Italian city of Messina and, on the basis of a report by Paul-Henri Spaak, agreed to re-examine the construction of Europe in the economic sphere. Two treaties were signed in Rome on 25 March 1957: one established the European Economic Community (EEC),

while the lesser-known treaty created the European Atomic Energy Community (EURATOM), devoted to the development of peaceful uses of nuclear energy. The authors of the treaties of Rome also aimed at eventually achieving an integrated Europe, but, as with the plans for a European Defence Community, General de Gaulle was opposed to the idea of a United States of Europe. In 1961, the United Kingdom, Ireland and Denmark applied for membership of the EEC, and Norway followed suit in 1962. True to his reputation as 'a minority of one', General de Gaulle refused to admit these new members, and once again vetoed an attempt at enlargement in 1967. Two years later, under President Georges Pompidou, France finally came around to the views of its five partners, and on 1 January 1973, the United Kingdom, Ireland and Denmark joined the European Economic Community. This was the signal for further enlargement with the entry of Greece in 1981 and Portugal and Spain in 1986, when the membership reached twelve. In 1995, Austria, Finland and Sweden were admitted, bringing to fifteen the total number of members of the European Union, the organization's official name since 1993.

At the Paris Summit of December 1974, it was decided that the parliamentary assembly in Strasbourg would be elected by universal suffrage, and that a European Council would bring together the Community's heads of state three times a year in order to reinforce cooperation between member states. The Single European Act, signed in Luxembourg in 1986, aimed to harmonize national legislation in such areas as taxation, the recognition of diplomas, social law and the right to asylum. The act also stated, albeit in timid terms, that the signatories would attempt to formulate and implement a joint European foreign policy.

The Maastricht Treaty of February 1992 expressed a resolve to continue the process of creating an 'ever-closer union' by enlarging the European Union to include a number of applicant countries emerging from communism and Soviet domination by strengthening the administrative structures in Brussels, and by launching a common currency, to be named the euro, in 2002. The United Kingdom, however, decided to continue using its national currency, the pound sterling. In March 1999, with a view to enlargement, the European Union conferred associate members status on three NATO members from Eastern Europe: Hungary, Poland and the Czech Republic.

Although potentially more powerful than the United States economically speaking, the European Union was not in the same league as the world's only remaining superpower after the collapse of the Soviet Union. Like the European Union, the new Russia was able to make its voice heard; yet even though its opinions were listened to and indeed sought, Russia did not have a decisive impact on the policies of the United States in the world at large.

The same could be said of China, at the turn of the century. Under the guidance of Deng Xiaoping since the late 1970s, the country has resumed sovereignty over the territories of Hong Kong and Macao, whose liberal economies fit in with Chinese reforms allowing for a mixed economy in which state enterprises exist alongside private businesses. However, China's future is challenged by a number of serious problems including social and human rights issues, the independent forces in Taiwan and separatist forces in Buddhist Tibet and Muslim Xinjiang.

## THE SCIENTIFIC REVOLUTIONS

Chapter 13, devoted to scientific development in the twentieth century, shows us that the number of discoveries made after 1940 is ten times greater than all those previously brought to light by humankind. Not only were hundreds of postulates revised or even discarded, rational approaches were undermined by the concepts of relativity and indeterminism. Modest laboratories with two or three researchers were replaced by large-scale institutions with state-of-the-art instruments. 'Big science' required costly and cumbersome equipment, using the most advanced technology. This was particularly true of sub-atomic physics and astrophysics.

In physics, Albert Einstein's theory of relativity and Max Planck's quantum theory had revolutionized concepts of time, space and radiation. Subsequently, Rutherford, de Broglie, Lawrence, the Joliot-Curies, Hahn, Strassmann, Meitner and Kurchatov laid down the foundations for nuclear physics, whose military applications – including nuclear weaponry in the context of the Cold War arms race – went hand in hand with peaceful uses (e.g. the development of nuclear reactors and power stations). It henceforth became possible to produce energy by nuclear fission as well as by thermonuclear fusion, the basis for the hydrogen bomb. If the process of fusion could only be controlled, it could become a practically inexhaustible source of energy.

The laser (an acronym for 'light amplification by stimulated emission of radiation'), an intense beam of light capable of being directed with extreme precision, became operational in 1968 thanks largely to the pioneering work of 1964 Nobel Prize winners Basov and Prokhorov (USSR) and Charles Townes (US). Laser technology led to important innovations both in quantum optics and in solid-state physics (Plate 18). Its many applications included boring though solids, excising tumours, disintegrating kidney stones and measuring distances. A laser beam focused on the Moon illuminates an area less than 2 km in diameter.

Progress in the field of radio astronomy enabled astrophysicists to obtain more detailed knowledge of the properties of stars, and, during the 1960s, to identify radiogalaxies (discovered in 1953) with quasars and pulsars.

The late twentieth century witnessed the construction of large land telescopes, such as the one atop the Mauna Kea volcano in Hawaii that scans the sky of the northern hemisphere, and the European Southern Observatory (ESO) in the Chilean Andes. The Hubble Space Telescope has increased our knowledge of distant galaxies and of extrasolar planets. Today, the field of cosmology, based on theories of general relativity and on astronomical observations, focuses on the structure and evolution of the entire universe. Detailed study of the Earth's structure and dynamics drew renewed attention to the previously rejected theories of continental drift and plate tectonics postulated by Alfred Wegener in 1912. Fifty years later these same theories revolutionized our image of the world.

The natural sciences devoted to the study of man – palaeoanthropology, anthropology, ethnography and prehistory – combined with techniques used in chemistry and physics and with excavations, pushed the emergence of our human ancestors further back in time. The *Australopithecus* skeleton found in Ethiopia, and nicknamed Lucy, is considered to be some 3.5 million years old.

In the twentieth century, biology caught up with physics. Indeed, the history of molecular biology and genetics is something of a saga. Both fields were condemned as bourgeois sciences in the USSR, and met with opposition in the United States, France and Germany. Nevertheless, between 1940 and 1965, scientists working in those disciplines identified the fundamental mechanisms governing the functioning and reproduction of living organisms. In 1944, it was shown that genes were made of DNA, the complete structure of which was described in 1953. Researchers expect to unveil the complete structure of the human genome in the early twenty-first century.

The astounding advances made in genetics and the resulting medical applications raise ethical questions, as they appear to pose a threat to the freedom of the individual. Less spectacular than the above-mentioned breakthroughs, yet equally important, new magnetic resonance imaging (MRI) techniques make it possible to watch the brain at work, and electronic microscopes enable cell biologists to appreciate the complexity of living cells.

As Professor Morange points out in Chapter 13, one of the aims of biology in the twenty-first century will probably be the combination of theories of evolution with developmental biology, molecular biology and cell biology.

Just like the natural sciences, the so-called human sciences made considerable progress in the twentieth century, involving philosophy, psychology, ethics, sociology, pedagogy, the different theologies, and problems affecting the status of women, young people, the elderly and the disabled. Specialists give an account of the progress made in these disciplines in Chapters 8 to 11 and 21 to 24.

## THE CONQUEST OF SPACE

Earth's first artificial satellite was launched on 4 October 1957. The short 'beep beep' sent back by the Soviet Union's *Sputnik I* was soon replaced by the much more complicated signals put out by other Russian and American satellites: *Lunik* 3, launched on 4 October 1959, which photographed the side of the Moon that we never see, and *Tiros*, the forerunner of the meteorological satellites. As the list grew longer, the general public lost interest, leaving specialists to follow new developments in the field.

Indeed, people appeared more fascinated by the exploits of the astronauts: Yuri Gagarin, Guerman Titov, Gordon Cooper and Valery Bykovski, who were joined in orbit by Valentina Tereshkova, the Komarov-Feoktistov-Yegorov trio, and Leonov and White floating in space. The world was waiting for the moment when a human being would set foot on the Moon, and the historic event finally occurred at 10.56 p.m. EST on 20 July 1969, when the two astronauts of *Apollo 11* landed on the Moon. Television viewers around the world could see Armstrong and Aldrin walking on the Moon and planting the Stars and Stripes on its barren surface (Plate 19).

In 1976, *Viking 1* and *Viking 2* explored Mars, apparently completely devoid of life, and found Venus equally inhospitable. The space probe *Voyager 2* set its sights on Uranus after photographing the rings of Saturn.

Despite occasional fatal accidents, astronautics continued, becoming increasingly international in terms of the sponsoring countries and crew members. The construction of the international inhabited space station was a thoroughly

joint undertaking, the different parts being taken into space by a succession of American and Russian vessels.

Meanwhile, hundreds of satellites were being launched for espionage, weather forecasting, radio, television and telecommunications (Plate 20). No sooner had space been conquered than it was threatened with congestion!

## THE INDIVIDUAL BECOMES THE FOCUS OF LITERATURE

As we have pointed out, several avant-garde movements emerged in literature and the arts after the First World War, but this was not the case in the aftermath of the Second World War. It was as if the horrors of the latter conflict, the institutionalization of genocide and the threat of atomic catastrophe called for a different perspective on life and the world. In their introduction to sub-chapter 26.1, Marc Bensimon and Astrid Guillaume point out that after the Second World War, writers were more focused on the individual and relations between individuals than ever before. This was true at the national and regional level and in the context of efforts to eradicate colonialism, racism and all other forms of oppression. These shared aspirations led to an international interplay of influences, and Russian writers such as Ilya Ehrenburg, Joseph Brodsky and Boris Pasternak were accordingly accused by the ruling regime of 'cosmopolitanism'.

Among the abundance of literature produced after the Second World War, works by women on all continents were particularly numerous and noteworthy, owing partly to the emergence and affirmation of women's rights, or, more precisely, to ongoing efforts to achieve equality of the sexes (*see* Chapter 8). Suffice it to cite the following examples: Rina Lasnier and Marie-Claire Blais (Canada), Aïssa Khelladi (Algeria), Emma Bel Haj Yahia (Tunisia), Nadine Gordimer (South Africa), Anita Desai (India) and Yamada Eimi (Japan). Alongside Alain Robbe-Grillet, two women, Nathalie Sarraute and Marguerite Duras, were the leading exponents of the *nouveau roman* in France. When that literary movement ran out of steam, many authors, notably Marguerite Yourcenar, turned to more classical forms of novel and theatre.

Observation of life and the behaviour of the individual led to the philosophical attitude illustrated in the novels and plays of Jean-Paul Sartre, which suggested an existential approach and defined hell as 'other people'. Albert Camus, less pessimistic, believed that humanity was not necessarily a lost cause.

During this period a large number of authors published autobiographies in a more or less disguised form. They included Günther Grass in Germany, Taha Husayn in Egypt and Nirad Chaudhury in India. Another distinctive feature was the impact of colonization and decolonization as found in the works of such gifted writers as Tahar Ben Jelloun (Morocco), Albert Memmi (Tunisia), Léopold S. Senghor and Sembene Ousmane (Senegal).

Sexual liberation advanced hand in hand with the feminist movement, and writers such as Henry Miller, Vladimir Nabokov and Yukio Mishima extended the boundaries of morally acceptable subject matter. An influential twentieth-century voice was English author George Orwell, who warned us of the invasion of the individual's private life by 'Big Brother' – the all-powerful State.

## THE INTERNATIONALIZATION OF CULTURE

One of the most striking features of the development of culture after the Second World War was the move away from the traditional centres of elite culture. In painting, the Paris School that held sway between the two world wars yielded its pre-eminence to the New York abstract expressionists. 'It is not surprising', observes Eric J. Hobsbawm in *Age of Extremes – The Short Twentieth Century* 1914–1991,

> 'that in the 1950s, in the heartland of consumer democracy the leading school of painters abdicated before image-makers so much more powerful than old-fashioned art. Pop artists (Warhol, Lichtenstein, Rauschenberg, Oldenburg) reproduced with as much accuracy and insensitivity as possible, the visual trappings of American commercialism: soup cans, flags, Coca-Cola bottles and Marilyn Monroe'.

In 1957, under the direction of modernist architect Oscar Niemeyer, work was begun on the construction of the city of Brasilia, which would replace Rio de Janeiro as the capital of Brazil. Beginning in the early 1970s, many artists experimented with post-modernism, which was not strictly speaking a movement, but a rejection of the dogmas of international modernism. In architecture, skyscrapers were cheerfully topped with 'Chippendale' pediments and other traditional decorative elements.

The outstanding characteristics of culture in the second half of the twentieth century, under the influence of old and new forms of media – records, tapes, radio, television (Plate 21), video, cable, etc. – were its internationalization and transformation into a mass phenomenon. One can, indeed, speak of the 'cultural industry' when decisions regarding the production, reproduction, storage and distribution of cultural goods and services are made on the basis of industrial or commercial criteria. Thus mass production is based on a marketing strategy that takes precedence over cultural development. However, such a strategy does not necessarily hinder cultural development and, in certain cases, it may even promote it.

In fact, one must marvel at the transformation of the cultural life of the great majority of those living in the West. Less than a century ago, even a very mobile music-lover would not have had the opportunity to hear Beethoven's Ninth Symphony or Bach's Third Brandenburg Concerto more than once or twice in a lifetime in concert halls seating no more than a few hundred. Today, thanks to modern communication technology any work in the concert repertoire can be enjoyed by 250 million people on a single evening. Moreover, each person can listen to the works again simply by recording the performance, purchasing a tape or CD, or by borrowing it from a library.

However, cultural industries do not necessarily have cultural objectives. In fact, the multinationals that have chosen this niche will create a product solely on the basis of global market research. Their initial approach is based on the same marketing techniques as those practiced by manufacturers of washing machines or motorcycles. Inevitably, their production is designed to appeal to average tastes at the national or international level.

As advertising increases and diversifies demand, cultural industries have recourse to symbols, images, ideas, myths and materials that become increasingly standardized, until we end up with what is called 'world culture'. This implies a 'star system' that focuses demand on a single performer and 'prototypes' that form the basis for a series of similar cultural products. This is particularly noticeable in the film and recording industries.

Star systems, prototypes and standardization call for abundant supplies of capital. Only on the international market can one hope to obtain a satisfactory return on the many kinds of investment required by cultural industries. Hence the world-wide distribution of American television serials such as *Dallas*, which premiered in 1978.

It need hardly be pointed out that the more limited a market, the less its aspirations are taken into account, and the 'smaller' the cultural identity, the more vulnerable it is.

## YOUTH, PROTEST AND COUNTER-CULTURE

Youth did not become a field of sociological research until the 1960s. In Chapter 9, François Dubet reminds us that the emergence of new behaviour patterns among young people as a category was one of the social changes characteristic of the twentieth century. Paradoxically, this change occurred essentially in the Western world, where young people were less numerous, more independent and better educated than in other regions.

The first carefully organized revolt broke out at the University of Berkeley, in the United States, in 1964. This time it was no longer the basically passive protest of beatniks dreaming of a lost paradise that could be rediscovered thanks to the heady delights of alcohol and ephemeral love affairs, or of hippies throwing off bourgeois taboos in a drug-induced state. It was a veritable movement.

Massive hippy gatherings such as Woodstock were not, of course, devoid of political content. Through their protest songs, Bob Dylan, Pete Seeger, Joan Baez and other stars had unambiguously opposed the Vietnam War, but they did not directly challenge the established social order, which was not unduly disturbed by their long hair, Indian-inspired clothes and blue jeans. In fact, blue jeans eventually became a mainstream fashion item suitable for both sexes, and particularly lucrative for America's cotton industry.

The Berkeley protesters, not content with deploring the absence of political freedom within the university, attributed it to a conspiracy between academic research, on the one hand, and the government and private industry on the other. Whether they knew it or not, they were propounding the theories of the philosopher Herbert Marcuse (*One-Dimensional Man*), who saw bureaucratic and state-dominated capitalism leading to a technocratic society that would take control of all forms of expression.

In 1966, student unrest crossed the Atlantic, creating disturbances at the Free University of West Berlin. Rudi Dutschke, the life and soul of the movement, was a refugee from East Germany who was dissatisfied with the regime in West Germany. In heaping scorn on liberal capitalism and Stalinist communism in equal measure, he was a typical leftist. The rebels soon diversified by denouncing the family as well as the university. All were now disciples of Wilhelm Reich, who wrote in his book *The Sexual Revolution*:

'The political function of the family is two-fold: (1) it reproduces itself by crippling people sexually. By perpetuating itself, the patriarchal family also perpetuates sexual repression with all its results: sexual disturbances, neuroses, psychoses, perversions and sex crimes; (2) it creates the individual who is forever afraid of life and of authority and thus creates again and again the possibility that masses of people can be governed by a handful of powerful individuals'.

In France, the protest movement led by Daniel Cohn-Bendit was launched at Nanterre University in 1968. Hoping to improve on Berkeley and West Berlin, the French protesters adopted a political stance and considered themselves a French revolutionary avant-garde movement, ready to instigate the overthrow of Gaullist power. After occupying university lecture halls as well as theatres and cultural centres, whose artistic staff willingly joined in, the protesters went on to set up barricades and resort to urban guerrilla tactics. On 13 May 1968, the Confédération Générale du Travail (CGT), a left-wing labour union, called for a 24-hour general strike. Was this the start of the revolution? The authorities were clearly at a loss: government ministers did not even know where to find President De Gaulle. The working class, which had initially participated in the protest by occupying factories, began to dissociate itself from the bourgeois youths and progressively to opt out. The Communist Party and the CGT were wary of leftism, and workers denied Daniel Cohn-Bendit and his friends access to the factories. The adventure had ended in failure, and de Gaulle took advantage of the May '68 'scare' to strengthen the powers of the Fifth Republic.

The period of violent protest in the 1960s coincided with the prosperity of an untrammelled consumer society. The recession of the 1970s was a different matter. Hardest hit by unemployment, young people had doors shut in their faces. Feeling rejected, many of them took refuge in sub-cultures, characterized by reggae or rap music, and sometimes in the violence of the skinheads and the temptations of the extreme right-wing ideologies.

Typically American phenomena included the 'Jesus Revolution' (*Jesus Christ Superstar*) and adaptations of Zen Buddhism. The Women's Liberation Movement and the Gay Liberation Movement soon took root in Europe where they eventually flourished.

The most influential and powerful of all the contemporary leftist movements is environmentalism, although similar ideas were sometimes expressed, albeit less forcefully, on the right of the political spectrum. Leftists have always regarded humanity's arrogant determination to subject nature to its arbitrary and unlimited power and to give economic considerations precedence over respect for the environment as a crime. Be that as it may, the American ecology movement, which was closely linked with Green parties in Europe, gained wide support in the industrialized countries. No longer the preserve of leftists, it became a worldwide movement, bringing about a timely and general awareness of humanity's responsibility towards nature, animals, plants, in short, towards life.

This seventh and final volume of the monumental *History of the Scientific and Cultural Development of Humanity*, like the six preceding volumes, is divided into two sections. In the first, dealing with specific themes, eminent scholars who responded to the call of the International Commission outline

the development and significance of achievements in their respective fields. In the second section, contributors focus on data collected on clearly delimited regions of the world and address issues specific to each region. The volume is completed by a chronological table, an index and selected illustrations.

The twentieth century, which has only recently ended, and in particular the post-1945 period, belongs to what is referred to as the 'immediate past'. The members of the Editorial Board of Volume VII are aware of the risks that this lack of perspective implies for historians and accept the criticism and discussion that the late Professor Charles Morazé foresaw with serenity in his foreword as further contributions to the cultural and scientific knowledge and interdependence of humanity.

# I

# THE WORLD AT THE BEGINNING OF THE TWENTIETH CENTURY CRISIS WITHIN IMPERIALISM

*Charles S. Maier*

## ORIGINS AND CHARACTERISTICS OF THE IMPERIALIST ERA

The history of world societies in the twentieth century presents some extraordinary general features, many of them continuations – in intensified form – of nineteenth-century trends. Among those that must strike even the casual observer would be the continuing revolutionary progress of technology – above all the use of non-human energy sources for production, transport and communication but also the great gap between those who benefited from such advances and those vast numbers still performing their agricultural work and manufacturing in traditional ways. In terms of world political organization, the striking characteristic of the beginning of the twentieth century was the extraordinary control that the relatively few technologically advanced societies came to exert on peoples elsewhere (what we commonly term 'imperialism'), and at least until mid-century, the bitter rivalry and destructive warfare between the imperialist powers.

Nor was imperialism the only pervasive inequality. The progress of technology also transformed social relations within states, establishing a particular sort of stratification in industrial societies based on access to scientific knowledge and on control of financial and industrial resources as well as the more traditional ownership of land or high governmental rank. Thus technological advance, the spread of political control over the less economically developed societies by the more advanced, social inequality, and world war were characteristics of an era that is often designated as the age of imperialism. This does not mean that imperialism alone established global inequality or that it made the world wars inevitable. However, these basic features of the era arrived as a historical constellation of forces and relationships. It is difficult to specify their causal interaction and to imagine that they did not impinge on each other in profound ways. In the chapters to follow, we examine their interrelatedness and their evolution.

## THE RESTRUCTURING OF TERRITORIAL STATES AFTER 1850

By 1900, the partition by the imperial powers of Africa and much of Asia as well as the major archipelagos of the Indian Ocean and the South Pacific had just about been completed. After the First World War, the territory of the Ottoman Empire in Asia and the German colonies overseas would be redistributed to other great powers. Increasingly during the interwar years, protest movements in some of the long-standing French and British domains would contest this colonial order. Nonetheless, only after the Second World War did most of the West's colonies achieve independence.

Still, to understand this imperialist world, one cannot simply begin in 1880 or 1890. It is necessary to take account of the great transition in developed state structures that had taken place a generation or two earlier, from the 1850s through the 1870s. The United States – once it overcame the Confederacy's military effort at secession (1861–65) – the states of Central Europe grouped in the German Confederation (1864–71), the states of the Italian peninsula (1859–70), emerging Meiji Japan (1853–68), the British in India after the Mutiny (1856–57), and to some degree, the Mexicans after defeating the French imperial expedition (1862–67), the reorganized Dominion of Canada (1867), and many other societies unified or reunified their state structures in this period. This transition involved transforming, often by force, confederally organized territories into more centralized federations.

The reorganized states applied the new technologies of railroad and telegraph to permeate the national space and establish a greater degree of hierarchic control from the centre. The process involved the social classes that were the agents of technological change, including bankers, industrialists, ambitious civil servants and engineers, who compelled the old governing elites, drawn largely from the landed classes, to share power and office.

The intellectual and governing elites of these cohesive nation-states rapidly adopted the new doctrines of Social Darwinism that inculcated notions of unremitting struggle for survival, not only among animal species, but so-called races and nations, and they embarked on a new period of rivalry and expansion. Once the Crimean War and the wars of Italian and German unification had yielded a new European order, they were soon followed by encompassing alliance systems within Europe and strategic competition to claim territorial possessions abroad. Equally striking was the rapid ascent of the non-European powers that had also undergone modernization. Less than thirty years after the Meiji restoration, Japan defeated the Chinese rapidly in 1895 and fought the Russians to a stalemate after spectacularly destroying their fleet. Three decades after its own long and costly civil war, the United States humiliated the Spanish by its rapid victories of 1898 and divested that long-standing empire of its last colonies, except its Moroccan enclaves.

The European powers (Spain, Portugal, the Netherlands, Britain, and France) possessed colonies since the era following Renaissance exploration. France had already annexed Algeria in 1830. Although for a few decades in the mid-nineteenth century doctrines of free trade had led to relative disinterest in territorial control overseas, by the 1870s and 1880s, the disparity between the power of the technologically advanced states and the more traditionalist and fragmented structures in Asia and Africa invited expansion. The Russians pushed into the multiple jurisdictions in the Caucasus and Central Asia in the 1860s and 1870s. Then, shortly after 1882, Britain asserted

financial control and political influence over Egypt. Bismarck was persuaded to support German colonies in present-day Namibia, Tanzania, and Cameroon by the mid-1880s. Pressed into *faits accomplis* by such ambitious imperialists as Carl Peters in East Africa, Cecil Rhodes in South Africa, and George Goldie in what would become Nigeria in the 1880s, the politicians of the metropoles worked to settle their potential rivalries at the Conference of Berlin in 1884, where King Leopold of Belgium won recognition of the settlements he sponsored as the Congo Free State. An Anglo-French treaty and Anglo-German agreement in 1890 cleared the way for British visions of more extensive settlement and development in the Lakes area (Uganda). British-French rivalry in the upper Niger area and all the way across to Chad led to another convention in 1898, whereupon London found itself consolidating British rule in Nigeria and the French hold on Chad. West Africa was no sooner settled than conflict loomed on the upper Nile and in southern Africa between Rhodes and the Boer Republics. The French gave up claims in the Nile region, acquiring, in return, recognition of their primacy in Tunisia and, in effect, Britain's acquiescence in their right to penetrate Morocco – and ultimately the quasi-alliance of the Entente Cordiale, which quickly developed into a mutual strategic tool for limiting German ambitions in Europe. The ambitious governor of the Cape Colony, Alfred Milner, who supported Rhodes and expansion into the Transvaal embroiled Britain in the costly Boer War. The Dutch-descended settlers were eventually forced to concede defeat but in effect won guarantees for the racialist policies within the emerging Union of South Africa. The process

reveals the underlying historical dynamic of world politics in the forty years before the First World War. While the enhanced power of Western nation-states led to policies of expansion, rivalry, and annexation in Asia and Africa, the conflicts over influence in these regions profoundly heightened the sense of confrontation among European nation-states.

During the same years, the British extended their acquisitions further in Burma, while the French expanded their control over Indochina. The Dutch consolidated their hold over Java, then moved onto northern Sumatra and Bali and the outer islands of 'the Indies'. Although China was too huge and venerable a state to colonize, the European powers forced the weakened Qing dynasty to cede extraterritorial jurisdictions along the coast and in Shandong. Japan would wrest Taiwan (Formosa) and extraterritorial enclaves in Manchuria from China in 1895, and establish the colony of Chosen (Korea) in 1910. The international force sent to subdue the Boxer Rebellion in 1900 served implicitly to demonstrate to China's rulers and citizens the strength of the Western powers and to mutually restrain the Europeans and Americans from unilateral acquisitions. The United States announced its stake in preserving China from partition (the 'Open Door' policy), even as this emerging world player took over Spanish possessions in the Philippines, finally defeating an indigenous resistance movement after several years of struggle. During the same period, the Americans also established a virtual protectorate over Cuba. By 1910, the only scope for expansion was for imperial powers to trade possessions, as in the second Moroccan Crisis, or to take them outright from each other. The Ottoman Empire, losing territory in Europe and lagging economically, seemed the candidate ripest for ultimate partition.[1]

## 'EXPLAINING' IMPERIALISM

Historians have long wrestled with large questions raised by this creation of the imperialist order. What motivated the sudden surge of colonial takeovers? How could such acts be accomplished and then maintained with such small commitments of men and arms? We can rephrase the issues as 'why imperialism?' and 'how did imperialism prevail?' The third question is perhaps even more difficult to assess and to answer: what effects did the experience have on the colonized, and the colonizers? But we shall address the first two questions here and postpone that of imperialism's legacy.

### Why imperialism?

Traditional historians from the imperialist communities have often interpreted this as a question of motivation, and have thus examined the stories and reasons given by the adventurers who set up colonies, the Roman Catholic and Protestant Church representatives who sought to evangelize, the soldiers who sought an opportunity for advancement after the period of warfare ended in Europe, the policy-makers who felt their countries must compete or accept a shameful decline. Justifications, however, are not motivations. One of the major justifications by colonialist enthusiasts was that the colonies provided an outlet for excess population, but these territories were often

inhospitable regions, and few Europeans chose to go, preferring the open societies of North and South America.

The more interesting approach to this question involves examining pressures on policy-makers that transcend individual motivation. We can distinguish two or three major interpretations, each with at least two sub-interpretations. Political historians of international relations, such as American scholar William Langer, argued that in effect the European powers looked to colonial acquisition as part of the continuing rivalry between states after 1870s. Since European space was crowded and divided and even the smallest claims involved warfare, it was natural to project rivalry into the non-European regions that seemed weaker. Since the European struggle was a Hobbesian one, states pressed into new territory – as Robinson and Gallagher later argued (1970) – to protect previous strategic commitments or because they were effectively 'sucked in' by continuing challenges at the latest frontier they had reached.[2] Thus an anti-imperialist prime minister, William Gladstone, found himself persuaded to intervene in Egypt lest the French do so and because control of Suez seemed necessary in light of prior imperialist commitments in India. Once in Cairo, expansion up the Nile allegedly followed because of the resistance that always came from beyond the frontier or the weakness that compelled further intervention. Such an explanatory approach had the virtue of allowing for step-by-step reconstruction of policy-making in the European capitals, but even when it discounted allegedly altruistic claims about teaching indigenous peoples self-government or bestowing Christianity or human rights, it also tended to be apologetic in its denial of any real imperialist agenda. Imperialist actions somehow always arose in response to conditions from the periphery that presented unpalatable alternatives: America took over the Philippines lest the Japanese seize them.

The second set of explanations has focused pre-eminently on the economic disparity between what would later be called the First World and the Third World. Non-socialist radicals Henry Wilshire, John Hobson and later Marxist-inspired theorists suggested that the advanced economies sought raw materials, cheap labour and new markets in the colonies. When it was realized that in fact the colonies – with the possible exception of the huge Indian domain – were unlikely to yield markets, another strand of neo-Marxian explanation was introduced by Rosa Luxemburg and others: namely that the process of capitalism involved a long-term tendency for the rate of profit on investment to fall (since surplus was provided by labour not capital, and as employers had to compete through investment in ore efficient production, they also condemned themselves to declining rates of profit).[3] In this perspective, the colonies might offer higher rates of profit. This insight was elaborated in different ways. John Hobson suggested that the search for profitable investment led to colonial expansion and was ultimately a result of the vast inequalities of wealth inside Britain. Rosa Luxemburg argued that the tendency for the rate of profit to fall under capitalist production necessitated a search for newer and more profitable investment arenas to be sought abroad.

Rudolph Hilferding, trained as a physician in Austria but taking up politics in Berlin, proposed that a unique structural fusion of banks and industries (so-called 'finance capital') made this search for higher rates of profit so imperative in the early twentieth century. Lenin borrowed

from Luxemburg and Hilferding but, writing in the midst of the First World War, examined primarily the investment rivalry in Eastern Europe and suggested that imperialism must be understood as a general stage of economic development inevitably leading to territorial conflict and, therefore, so he predicted, to the chance for revolution.[4]

A later variant on Marxist notions of class conflict – but advanced by analysts who would claim to be influenced by, but not adherents of simple Marxism[5] – suggested that the process of industrialization had unleashed such a sharp degree of class-conflict that manipulative governments chose foreign adventures to take the minds of the masses off domestic claims.

In all these views imperialism had a certain logic or rationality within the terms of the capitalist system. This meant that imperialism might end only with the final transformation of capitalism. Only Schumpeter (1915) claimed that imperialism in fact represented a non-rationalistic or 'atavistic' hold over pre-capitalist aspirations (which the existence of protective tariffs in Central Europe helped to preserve) and that ultimately capitalism would destroy imperialism, a theory similar to that proposed by the Norwegian-American economist Thorstein Veblen.[6] Historians have repeatedly sought to test these theories, finding in general that imperialism did not really 'pay' national societies in aggregate, but that, as Hobson or Schumpeter recognized, it did pay key elites who made policy at home.[7]

Most recently, non-Marxist authors have proposed that the long history of British imperialism is best explained as a result of 'gentlemanly capitalism', which refers to an effort by men of property and culture, less involved with industrial management than with banking and services, to sponsor overseas empire that established them as a patrician elite in a conservative social order.[8] Nonetheless, to this author the political motivations – the fear of international political rivalry marked by arms races, alliances, as well as overseas expansion – seem to have provided the more urgent agenda.

**How did imperialism prevail?**

Why and where did Europeans prevail? How could such small expeditions of Europeans conquer such vast regions and then administer them at such little financial expense? Theories here are less developed. Of course, the European states enjoyed decisive technological advances: gunboats and ships, the latest weaponry. Nonetheless, defenders of autonomy could also acquire at least small arms, and Europeans did meet defeat at the hands of indigenous defenders: the British by the Zulus in the Battle of the Spears (1879), the Italians at Denali (1887) and Avowal (1896). But, in fact, the Europeans also possessed a different sort of resource, which in a broad perspective can also be construed as a technology: that is, the modern state equipped with functionally developed bureaucratic organization, permanent armed forces and obsessed with the notion of frontier and territorial control that the more fluid or even nomadic states had not chosen to develop.

It is too simple to divide states and tribes (which often was a pejorative concept).[9] Africans, of course, had political structures, some very extensive and highly organized, but the states that sent their soldiers and agents into the periphery were of a different order. State structures were unwieldy and sometimes inefficient in modernizing Ottoman Europe or Qing China, in the interior of the Maghreb or 'black' Africa. Often, the states that Europeans encountered (as was the case of the Aztec and Inca empires in the sixteenth century, or the American Indian confederations, Iroquois, Creek, Cherokee, etc., in the eighteenth and nineteenth centuries) were themselves recent creations and, in any case, agglomerations where some tribal units aspired to recover independence in league with Europeans. The Europeans had centralized in the 1860s and drawn on new technological resources for territorial domination, whereas the states they encountered had not made this transition. Where Asians or Africans did undertake similar reforms, they did not succumb. Japan was the pre-eminent example, itself becoming an imperial power. The mid-nineteenth century monarchs imposed a programme of state building on Thailand, which had the good fortune to remain a buffer between British and French colonial territory, as Persia (Iran) did between Russian and British. Elsewhere the very ancientness of dynasties and states sometimes gave them the legitimacy to stand up to invaders, as in Ethiopia until 1935–36 and, of course, China.

## GLOBAL INEQUALITIES AROUND 1900

All in all, however, the imperialist world reflected a high point of hierarchical distribution of resources: political and economic. If we envisage the imperialist world as a phase of world history, as seems proper, then both in terms of economic resources and political power and both within states and between them, the imperialist world of 1900 incorporated a high if not the highest degree of unequal distribution of resources that the world had seen to date.

The historian cannot claim that such differences would not have existed without imperialism. In a Leninist theory, it is precisely the differences of development that give rise to imperialism (which includes economic penetration and foreign investment). The real role of imperialism was to help perpetuate this differential development. By and large, two theoretical stances have contended in trying to explain the outcomes. The heirs to older theories of imperialism – especially the 'dependency theorists' active thirty years ago – proposed, in effect, that Western enrichment depended upon Third World poverty, that some mechanism existed where the poor nations were poor because the rich were rich and vice versa. It was structurally logical for high-wage societies to maintain the poverty of low-wage societies.[10] Such a view found an echo in the United Nations Conference on Trade and Development (UNCTAD), although it was always sharply contested.

Since 1980, with the general disillusion with Marxist theories, more culturally oriented notions have become dominant. Such thinking, perhaps represented most succinctly by the work of such specialists as David Landes and Francis Fukuyama, proposes that a commitment to education, thrift and accumulation, the rule of law and honouring of contracts, and networks of trust, have been crucial for economic development.[11] Obviously, the representatives of poor ex-colonial countries can be consoled by the first view, while those proud of First World achievement enjoy the second. The original notion of dependency theorists that wealthy countries had a stake in

Third World poverty seems unsustainable. However, colonial rulers and investors from wealthy countries often tended to freeze levels of development or encourage activity that autonomous elites might have shaped differently. While the proportion of economically active people engaged in agriculture fell by 1910 to about 5 per cent in Britain and Belgium, about 25 per cent in countries that industrialized but kept significant agricultural sectors active, such as the United States and Germany, and remained from 40 to 60 per cent in the less developed European lands, such as Spain and Italy and in Eastern Europe, the countries of Africa and Asia remained overwhelmingly peasant societies (c. 65–75 per cent).[12] Still, analytically we cannot know what the hypothetical alternative in the absence of imperialism might have yielded: autonomous national development as in Japan, or no development? What percentage of rent from mineral resources might be considered justifiable for the European owners of mines – that prevailing in developed countries or a higher one, if these resources had otherwise lain undeveloped? Ultimately moral criteria and not historical research must be applied to answer these questions.

The inequality between nations was matched by the inequality within nations. Europe was richer than it had ever been, but income, and even more so, wealth was highly concentrated. In many societies and regions – the southern states of the United States, Romania and the Balkans, southern Italy or Andalusia – agriculture remained backward and landlords controlled a labour force of poor peasants, who themselves had often lost their land, remained in almost perpetual heavy debt, or lived as day labourers on the great estates. Political conditions reflected these quasi-peonage societies: landlords could control the votes of the peasantry and trade these electoral supporters for patronage and favour from the capital. Great landowners received enormous revenues from their tenants and often from the rights to coal and other minerals on their territory. In some societies, these distinctions of wealth did not matter in assuring political representation; but in Germany and its states, political representation was skewed according to tax payments, favouring the wealthy. In Britain, where no revolution had redistributed property, the inequalities were the highest in Europe, although America was on its way towards equivalent stratification. Such inequality was perfectly compatible with economic development, advance, and often growing welfare.

Indeed the European societies were initiating the first stages toward what later became known as the welfare state. Bismarck introduced social insurance for illness and old age in Germany in the mid-1880s; he was motivated by conservative calculations and a concern to weaken the advance of the Social Democrats among the growing industrial working classes. The British Liberal government of 1906 enacted similar measures. In France and Catholic countries, more paternalist schemes of social insurance tied to the employer were launched. While the federal government of the United States would not intervene until the administration of Franklin D. Roosevelt during the world economic crisis, some of the states under progressive control introduced regulations for minimal wages and maximum hours. In fact, throughout the European and American world, women's work, as well as hazardous occupations such as mining, were increasingly regulated. Child labour was being eliminated in most sectors.

However, the non-Western world operated by different rules. Whether in the Congo up to the 1880s or in Latin American mining ventures (the Putumayo scandal broke in 1910), Europeans felt little restraint in imposing the harshest of labour conditions. Joseph Conrad captured the 'otherness' of the imperial experience: the fact that almost every abuse of power might be undertaken because it remained invisible (except for the occasional horrifying scandal, such as that of Leopold's Congo, or the atrocities of the German war to suppress the Herrero) and European military adventurers were effectively uncontrolled. Nonetheless, the more pervasive and widespread effects of imperialism were probably subtler than the horror stories depicted in *Heart of Darkness*. Distinctions were made between those supposedly fit to rule and those destined to serve: the presumption was that colonial subjects were childlike and capable of only certain stages of intellectual or administrative attainment, and that colonial development was designed to serve the purposes and wealth and the ego satisfactions of master races far away.[13] To be sure, thousands of missionaries were motivated to found educational and medical institutions. Still, they pursued their work symbiotically with the traders and the politicians. Essentially imperialist apologists claimed that vast areas and populations must wait indefinitely to enjoy the collective autonomy Europeans had come to take for granted since the Enlightenment and French Revolution. In an era that seemed to prize national independence as a supreme human value, the defenders of imperialism maintained that many of the world's peoples were not yet mature enough to claim it.

## CRISES OF THE IMPERIALIST POWERS, 1900–1918

### Two types of empire

From antiquity to the twentieth century, empires have played an ambiguous role in international relations. By subjugating fractious ethnic rivals, they can help ensure regional peace within their borders, but their frontiers remain sites of recurrent skirmishes, and as they decay, conflict becomes endemic. International structures at the beginning of the century included two sorts of imperial systems, and each type was becoming more a source of potential conflict than a guarantor of regional order.

The first and older set of empires comprised the extensive land-based monarchies based on a dominant ethnic group that had subjugated peoples on its peripheries. Nineteenth-century nation building in Western Europe had left the ethnic peoples remaining in the multinational empires restive and ambitious. The Austro-Hungarian Empire included about ten recognized ethnic or linguistic groups, governed in two sub-units: the Kingdom of Hungary and the Austrian half of the monarchy. Within the Austrian half, Czechs, Poles, and Italians contested the Germans' hegemony, and the dynasty sought to represent all the peoples. Within the Hungarian half, South Slavs (Croats, Serbs) and Romanians aspired to more rights, and the national groupings outside the border ambitiously looked to influence their *irridente* within the Habsburg realm. By the late nineteenth century, periodic crises over language and school rights paralyzed parliamentary life.

The decomposition of the Ottoman Empire was even more advanced. During the course of the nineteenth century, Greeks, Serbs, Romanians, and Bulgarians had progressively won their independence. The Ottomans attempted periodic reform in the nineteenth century, introducing some parliamentary institutions, but the reformers, who pressed for more parliamentary government, usually supported a stricter imposition of Turkish national policies as well, provoking ethnic discontent.

The Russian Empire, based on the expansion of Muscovy, included: Poles, Ukrainians, Finns and other Baltic peoples in its western areas; Georgians, Armenians and diverse peoples of the Caucasus; the states and former khanates of Central Asia; Buryats in the east; as well as diverse ethnic groups within Russia proper, such as Germans and Tatars, Bashkirs, Udmurts, Kalmyks among others. As of 1900, Russia was less subject to centrifugal decomposition but was caught up in the rivalries over Korea at its eastern limit and the Balkans on its south-western periphery. China, strictly speaking, was less of a multinational or multicultural empire; although its inner-Asian frontiers included Turkish, Uighur, Mongol and other non-Chinese regions, it faced more serious disintegrative threats along its coastal regions, which Europeans were taking over as their own enclaves – by outright cession, long-term lease, or extraterritorial concession.[14]

The other type of empire was precisely the overseas colonial domains and protectorates cited above. As of the early twentieth century, the problem they presented for international relations was less the restiveness of unwilling subject peoples (although major conflicts took place, especially the United States' campaign to subdue a Philippine independence movement after 1898 and the German campaigns in South-West Africa against the Herrera rebellion) than the competition among the Europeans themselves. The rivalry for overseas empires was one of the considerations that led the Germans to attempt a naval armaments challenge to the British between 1898 and 1910. Colonialism and 'navalism' – now justified by the tracts of the American Admiral Mahan[15] – went hand in hand. Colonial expansion was a stake in the larger strategic competition among the European powers, but it also threatened to make that competition far more dangerous, as the domains available outside Europe for partitioning were successively appropriated. By 1900, most had been carved up, although the Japanese annexed Korea in 1910 and Manchuria in 1931, while the Italians seized Libya in 1912 and Ethiopia in 1936.

Crises over respective colonial domains or conflicting ambitions for potential colonies became more preoccupying. As mentioned above, imperial rivalries shaped European alignments. The French and British confrontation at Fashoda near the headwaters of the Nile in 1898 helped to prompt a rethinking of their relationship. Both powers, after all, were preoccupied by German ambitions, and Britain also watched uneasily as Russia (allied to France) and Japan (its own new ally in the Pacific) moved closer to war over their conflicting ambitions to control Korea. These motives prompted London and Paris to work toward the Anglo-French Entente Cordiale of 1904, designed to forestall any undesired tangles and also to coordinate defensive planning against Germany. The Americans took the Philippines from Spain in 1900; the Germans threatened the French paramount position in Morocco (not formally a colony) in 1905, and again in 1910–11, and the latter confrontation resulted in a frontier adjustment between German and French possessions in Cameroon.

## Alliances, armaments, and origins of the First World War

A distinctive feature of the evolution of international relations after the unification of Germany and Italy was the formation of fixed military alliances in peacetime: the Dual Alliance between Germany and Austria-Hungary of 1879 (enlarged a few years later into the Triple Alliance with Italy, which was less likely to function successfully) and the Franco-Russian alliance (1894), which was a response to the former. Through the 1890s, the ruling British conservatives believed that their maritime supremacy allowed it a policy of 'splendid isolation', but the Fashoda crisis, the German naval challenge and the fact that every other power aspired to the colonial position Britain had acquired made it look for support to Russia in 1902 and to France in 1904. In 1907, the British further interacted with the Russians, their long-standing rival in Central Asia, in order to protect against a conflict over Persia or India and Afghanistan. Effectively, although they tended to deny it to themselves, Britain had been locked into the bipolar competition.

Not only alliances but also significant arms races were involved. Conscription levels were raised in Germany in 1893 and 1913 (bringing the peacetime army to 864,000); the French switched from two to three years of mandatory military service in 1912. Given the fact that young men faced reserve requirements for many years after active service, as well as the perfected logistics of railroads (in the French mobilization of 1914, only 20 out of some 4,300 trains were late), the major powers on the Continent could have approximately two million men at battle stations within a few weeks. Their war plans provided for about half to be deployed rapidly and, in the case of Germany, pre-emptively.[16]

Such military alliances and arms increases might have been accommodated without war (after all the Warsaw Pact and NATO confronted each other with high levels of arms from the 1950s through the 1980s). The problem was that the Ottoman and Austro-Hungarian empires were subject to disintegrative pressures, and the conflicts these created involved links to the new colonial powers. Russia and Japan went to war over their rivalry in Korea, itself a stake for their respective aspirations because China had shown itself so feeble vis-à-vis Japan in 1895. Germany attempted to demonstrate the weakness of the Entente Cordiale shortly after its announcement by an ostentatious demonstration challenging the French predominance in Morocco. The Reich, however, emerged isolated, except for its Habsburg ally, thereby guaranteeing closer Anglo-French cooperation. The European situation became even more unsettled when the Austro-Hungarians, concerned by their own failure to share in colonial acquisitions, decided to annex neighbouring Bosnia, the former Ottoman dependency that the Congress of Berlin had awarded Vienna as a form of trusteeship thirty years earlier. Russia was angered at this unilateral expansion, as were nationalist Serbian circles that aspired to unify the ethnic Serbs of the province. Austria's ally, Germany, compelled Russia to

accept the *fait accompli*. The Italian government, preoccupied by Austria's annexation of Bosnia and anxious to win nationalist public opinion at home, took advantage of Turkey's new difficulties to seize Libya as a colony in 1911. Continuing Turkish weakness led the Balkan states of Serbia, Bulgaria, Greece and Montenegro to conquer the territory of Macedonia, and they soon fought a second war among themselves over the division of territorial spoils. Concerned with the growth of Serbian strength, Austria, in collaboration with Britain, forced a settlement that established the new state of Albania, designed to keep Serbia from acquiring an Adriatic outlet. Consequently, by 1914 the international system was very brittle.

Particularly disturbing were the mutual suspicions of Russia and Germany; each believed itself increasingly vulnerable. Berlin military planners were convinced that the modernization of Petrograd's railroad system around 1917 would facilitate rapid mobilization of Russia's massive army and thus undercut their strategy for dealing with the danger of a two-front war. Influential members of the General Staff contemplated pre-emptive war in 1912 and 1914. Russia was certain that Germany was bent on penetrating the Balkans in league with Austria and propping up the Ottoman Empire. French policy-makers actively reassured their Russian allies that Paris was a reliable partner in case of a showdown.

When the Austrian heir apparent, Franz Ferdinand, was assassinated by Serbian-assisted terrorists in Sarajevo on 28 June 1914, it took some time to understand just how critical the crisis might become (Plate 22). The chief of the Habsburg General Staff was determined to thwart Serbian aspirations, and the more cautious heir apparent was no longer around to argue against the chief's reckless policies. In early July, the German ministers believed that they must show support for their Austrian allies, while German military leaders persuaded themselves that this might be the last chance to take on a huge, modernizing Russian army. Russia, with France's implicit support, was determined that it would not accept further *faits accomplis*. The French president and government felt they had to show full support for their allies' firm stance. By the end of the month, when British leaders had become truly alarmed and sought a joint mediation with Germany, Berlin refused to rein in its Austrian ally. By the first days of August, the continental powers were at war, and to Germany's dismay, the British Liberal coalition decided it could not ignore the obligations it had incrementally negotiated with France. With Britain came the 'White' dominions: Canada, Australia, New Zealand, and even the new Union of South Africa despite some Boer hesitations. India and other colonies had little choice. The Ottomans joined Germany by the end of 1914; Italy attacked Austria the following spring; Bulgaria sided with the Central Powers, Romania joined the Entente and the United States finally intervened on the side of the Entente as an associated power in April 1917. Other countries, notably Portugal, Brazil, Japan, and China, soon aligned themselves with the Allies to maintain goodwill.

## The war's impact on imperialism

What was the relationship of the war to the imperialist international order? Did the overseas empires exacerbate or displace conflict? For a generation after 1870, the nations of Europe had carried out their rivalries by conquests and competition in the 'periphery', i.e., Asia and Africa, but that competition, of course, magnified the overarching sense of Darwinian struggle at home. The war finally resulted from rivalries among European powers largely over European issues. The nationalist aspirations of the peoples of Eastern Europe, many of whom were still included within the land-based European empires, and the limited capacity for institutional reform on the part of the Ottomans, Austro-Hungarians, and Russians, led to continuing conflicts. The old empires ignited the war as they resisted ethno-national pressures, and the war eventually destroyed them.

The war required an unprecedented mobilization of resources: what General Ludendorff called 'total war', such that by 1918 Germany, Britain, and France were perhaps devoting 40 to 50 per cent of their GNP to military uses. On the western front, the Germans' rapidly invaded Belgium and France with devastating casualties, but after failing to reach Paris, the two sides dug into trenches that remained largely stable (although heavily and disastrously contested) until the great German offensive and subsequent retreat of 1918. Almost one man in four between the ages of 18 and 40 would be killed among the French military. The toll on Germans was slightly lower, but a higher number of men were killed (1.3 and 1.8 million respectively). In Eastern Europe (outside Serbia), the percentages might be lower, but this resulted from the fact that the armies were not frozen into fixed entrenchments and huge numbers of troops were captured en masse.

The Russian Empire collapsed first. Its massive armies enjoyed a few weeks of initial success in East Prussia, then committed some disastrous strategic errors and suffered a major defeat at Tannenberg. German and Austrian victories forced withdrawals in Galicia (a region in present-day Poland and Ukraine) in 1915, and the military recovery under General Brusilov in 1916 could not be sustained. Troops fought stolidly but with inferior equipment. While improved in 1916, industrial support was deficient. Motivation flagged as retreat continued, and with surprisingly little resistance, the prospect of mass mutiny led to the tsar's abdication and the declaration of a republic in the 1917 revolution. In the confused conditions of wartime Petrograd and the sudden political competition, the provisional government lost almost all authority. Its decision to continue the war effort along with its allies cost it major support. Returning from exile, the Bolshevik leadership established its authority in the factory councils ('soviets') as well as in the workers and soldiers councils, while the reformist socialists (Mensheviks), the professorial Liberals, with limited support in middle class and professional circles, and even the would-be representatives of the peasantry, the Social Revolutionaries of Alexander Kerensky, could not establish effective political control. Having maintained the most radical anti-war position, the Bolsheviks knew what they wanted, and seized power in a *coup d'état* in the so-called October Revolution, in which a party with hitherto a weak position took precarious control of the Russian State. Dissolving the recently elected Constituent Assembly in which they had only about a quarter of the delegates, the Bolshevik leaders skilfully announced a new International to win support abroad for an attractive programme of immediate land redistribution to the peasants, and peace without annexations. The new regime accepted huge cessions of the former tsarist realm in Eastern Europe to make peace with Germany, and mobilized

supporters in what became a brutal civil war on multiple fronts. Despite Western support for their adversaries, the Bolsheviks prevailed by 1921. Hand in hand with the most exalted promises of world proletarian revolution came the organization of an effective secret police, the Cheka. Opposition parties and eventually the competing factions of the revolutionary front were successively suppressed. Lenin was ruthless toward opposition, but also understood that in a period when violence had become a worldwide phenomenon, the rhetoric of liberal politicians was limited. To win the civil war, he announced war communism, resorted to class warfare in the countryside, requisitioned property. He ostensibly promised self-determination to the diverse ethno-national components of the empire, which for several years became arenas of struggle on their own before being safely centralized again within the reorganized Union of Soviet Socialist Republics.

The Ottoman and Habsburg empires also collapsed under the massive strains of war and economic hardship. The Habsburg armies held up surprisingly well, if assisted by German cadres, but as the Central Powers went into retreat, the empire finally decomposed and the various national leaderships declared independent republics. In Turkey, the Sultanate was left isolated in Constantinople, while Mustafa Kemal's Turkish nationalists seized control in Anatolia, replacing the old regime by 1922. While the German Empire was more of a nation-state, it too collapsed with defeat. The land empires in effect disintegrated.

However, the First World War did not achieve the formal independence of colonial regions overseas. Decolonization was to be achieved only after the Second World War. The situation of the extensive and populous areas of the world still held in colonial dependency was fraught with contradictions after 1918. The ideology of the victors centred on the concept of self-determination – for Serbs, Poles, Czechs and Belgians, but not for colonial peoples. According to British and French imperialist doctrines, colonial subjects would be ready for self-rule only after an indefinitely long period of 'preparation', either through indirect rule by cooperative Christian-educated university-trained indigenous elites, or through inculcation with the French republican values that Paris propagated. But that time was still far off.

No matter how devoted American policy-makers were to Wilsonian ideals, they were hardly prepared to recognize their relevance for the Caribbean and Central America. And the Japanese leaders, who had pursued an imperial agenda since taking Formosa (Taiwan) in 1895 and Korea in 1910, sought to exploit their country's intervention on the Allied side in the First World War to establish their country as the dominant power in Manchuria and the Shandong peninsula at a time when northern China succumbed to fragmenting successor battles after the collapse of the Qing Dynasty. Although Western objections helped China resist Japan's Twenty-one Demands for a protectorate, and the Chinese claimed a place at the Paris Peace Conference by joining the coalition against Germany, the 'Big Four' negotiators still awarded Japan control of the former German possessions in Shandong. Angered by this dismissal of their own country's national rights, Chinese students and protesters organized a huge protest – the 'May Fourth Movement' – against foreigners and the weakness of the fragmented Chinese regime. Still, Western recognition of Japan as a major Pacific naval power helped Tokyo

pragmatists maintain decisive power at home through the 1920s and postponed a war for hegemony in the Western Pacific.[17]

The First World War had clearly shaken the premises of colonial rule. The British and the French had brought the indigenous peoples of their African and Asian domains to assist in the Great War: Senegalese troops served in the French occupation forces in Germany; Indian army units had fought in the Mesopotamian campaign against the Turks. The Indian Army was expanded to two million men, and the country was taxed and subject to war loans to pay for their upkeep. Labour battalions recruited from Egypt and the West Indies, or hired on a contract basis from China, built railways, supply depots and unloading ports in France. Colonial subjects who travelled to the theatres of war (or fought themselves in the African and Ottoman campaigns) were plunged into a world where whites no longer presented a united front, as they had during the Boxer Rebellion, but were visibly bleeding each other to death. They were sometimes introduced to Marxist ideologies of pacifism and other underground ideas of anti-war protest. Even when they remained resistant to unrest, they then had to return to their galling subaltern roles in the colonies.[18]

Moreover, Woodrow Wilson and America's role briefly crystallized an almost messianic sense of expectation among many spokesmen for the working classes and for independence worldwide. The Paris Peace Conference was fraught with the sense of a transformed world order, and the representatives of Korea, China, Egypt and many other hitherto colonized nations expected the situation to be redressed.[19] The colonial economies, meanwhile, had been infused with new vigour as the belligerents called for raw materials and manufacturing. Colonial areas were not immune to the waves of working-class and revolutionary unrest that surged throughout the world from 1917 to 1921. In India, above all, the Congress Party had already put self-government on its agenda, and a vigorous labour movement had emerged. Protest movements and strikes were renewed. Nonetheless, colonial authorities were determined to maintain 'order', and the movement ran its course, with several incidents, the bloodiest of which occurred in April 1919 in the Punjabi city of Amritsar, where the heavily armed British commander killed nearly 400 and wounded 1,200 Indian protesters who had rallied in a local stadium.

The victors in Europe, in short, were not prepared to relinquish their domains. The key to the peacemaking process outside Europe was not imperial divestiture, but sufficient agreement on joint approaches by the colonial powers and appropriate redistribution of German or Ottoman possessions to make future conflict unnecessary. By 1916, the French and British had agreed that they would divide Ottoman possessions in the Middle East after an Allied victory. The French, who had long-standing commercial and religious interests in the Christian and Druse settlements of Lebanon and the north-western part of Mesopotamia, were awarded territories south of Turkey, which they divided into the two 'mandatory' republics of Lebanon and Syria. Further to the south along the Mediterranean and extending eastward across the Jordan River, the British took over Palestine and the newly established Kingdom of Trans-Jordan. They also received the long sweep of 'Mesopotamia' from the Persian Gulf to

Syria (to be reorganized as Iraq), making sure to retain the oil-rich area around Mosul.

To reconcile abstract Wilsonian ideals with the colonial appetites that the war had enhanced, the new League of Nations was empowered ostensibly to assign the redistributed German colonies as 'mandates' to the existing imperial powers: France and Britain in Africa, Japan and the United States in the case of Micronesian island possessions. Called on to ratify partition agreements made among the major powers, the very organization that promised a peaceful world order could thus be exploited to sanction a new lease on life for European colonialism.

Organizing political authority in these regions remained a somewhat improvisational task. The British recognized the independence of the Bedouins of the Hejaz, who under Sharif Husayn had thrown in their lot with Britain against their nominal Turkish overlords. Although Husayn's ambition to be caliph of the Arabs did not long survive the war, one of his sons was installed as leader of Iraq, while the other was awarded Trans-Jordan. London retained direct administration of the remaining western area of Palestine, where they had somehow to reconcile the interests of Zionists – who had been promised a Jewish homeland by the Balfour Declaration of 1917 – and resident Arabs. In the Arabian Peninsula, where an eighteenth-century revivalist movement had brought the house of Saud to power, the hereditary leader Ibn Saud consolidated the interior territories, conquered the Hejaz by 1925–26, and in 1932 proclaimed his domains the Kingdom of Saudi Arabia.[20] Egypt continued as a kingdom under British protection; like India, it had become an important economic component of the imperial textile industry. Thus London had acquired a vast domain of semi-autonomous protectorates, theoretically ruled by the newly inserted institution of monarchy, but in fact governed by a fitful alliance of influential families and London resident authorities. The Dutch retained their rich possessions in 'the Indies'; the Union of South Africa took over German South-West Africa (Namibia) as a mandate. The French set out to consolidate their influence in Morocco, Lebanon, and Syria and to win over the Syrian elites. For both France and Britain, the training of indigenous military units was a key task.

The demands of the First World War revealed how useful a role loyal colonial forces might play. Indian forces had been critical in the Mesopotamian campaigns; Senegalese formed part of the post-1918 French occupying force in Germany. The armies also offered a channel for training key elites and inculcating a sense of belonging to an overall colonial mission, but positions of command remained reserved for the Europeans. Could the loyalties engendered among the colonial elites overcome the enhanced ideologies of self-determination? After indulging in four years of unprecedented organized violence against each other, could Europeans truly reconstruct a united front to rule so many non-Europeans, especially when their rivalries had contributed to their sanguinary conflict? And after expending so many of the resources offered by the colonial world for that cause? Far-sighted statesmen in Europe as well as nationalist leaders understood that the system had to evolve, but the wager for the colonial powers was that some new form of association that would preserve their cultural and economic ascendancy might painlessly emerge. Had they not been so embroiled among themselves in the wake of the First World War, they might have had a better

chance. Once the upheavals of 1919 were suppressed or dissipated, however, the imperial order seemed to have acquired renewed lustre. Empires existed on borrowed time, but even that would eventually seem intolerable to those who were asked to wait.

## STABILIZATION, CRISIS, AND THE SECOND WORLD WAR

*Charles S. Maier*

### PROLONGING COLONIAL RULE

As before the First World War, events in Europe had a direct influence on the colonies. Imperial control was more extensive but also more precarious. The inter-war phase of European domination involved a race between reform and rebellion. Progressive Europeans hoped for gradualist co-optation of local elites in an effort to forestall real independence, but by the inter-war era, they had to deal with the growing impatience and skills of a new generation of politicized and educated indigenous leaders. Right-wing European critics of colonial reforms correctly predicted that continued concessions would only lead to increasing pressure for independence. But their only alternative was the recourse to force. Ultimately the British would recoil before the violence that would have been required, while the French accepted it (after the Second World War), only to find that their own society was brought to the edge of civil war.

As the threat of aggression from Germany, Italy, and Japan grew far more menacing by the mid-1930s, London's military resources – the ultimate coin of empire, even if rarely spent – were stretched very thin. Troops were required for security in Europe, initially in Ireland, in Palestine and the Middle East, and eventually South Asia. The duration and demands of the First World War had already made London dependent on the reserves of wealth and manpower contributed by the self-governing dominions and also on the financial support of the United States. In Britain's major possession, the Indian subcontinent, further cessions of authority to the nationalist movement were virtually inevitable. British reforms announced in 1917 and formalized in the 1919 Government of India Act began a partial movement toward self-government within the Raj. Under a notion of diarchy, education, agriculture, and health were to be devolved upon provincial legislatures elected by Indian constituencies. Revenue, law, and order were to be reserved for the vice-regal government.[1]

The British were not prepared to relinquish India between the wars, and the movement for self-government in India (the National Congress) still believed caution was required. In the wake of the Amritsar massacre, Mohandas Karamchand Gandhi, the remarkable ascetic 50-year-old leader of resistance, moved in late 1920 to transform the Congress Party into a more effective mass organization and initiate a campaign of civil disobedience – non-cooperation – for the sake of self-rule and ultimately independence (Plate 23). Social pressures added to nationalist grievances. Wartime provisioning requirements for the large Indian army had stimulated Indian textile and other industries in Bombay, Madras, Bengal and elsewhere. Overarching potential urban and rural class conflicts were the fundamental fissures of the huge articulated set of communities that constituted India: the gap between the untouchables, whom Gandhi insisted must be included in the Congress to the instinctive repugnance of upper-caste leaders, and the division between Hindus and Muslims, led in the Congress by Mohammed Ali Jinnah. The more urgent the demands for national independence, the more fissured the subcontinent appeared. British resistance to further reform after the dominion proposals of the abortive Simon Commission led to a five-year campaign of civil disobedience from 1930 to 1931, including a dramatic march to the sea to protest the salt tax, and again after 1932.

An Indian nation had to emerge, but when, and what cohesion might it possess? The final pre-war British answer was the Government of India Act of 1935, the upshot of initial Round Table Discussions with Indians in 1931–32. It envisaged a federal dominion when half of the princes (subject to the Raj but ruling a quarter of the population) might agree and, in fact, served as the basis for the post-war constitution. But until ratification by the princes, power would remain with the Viceroy. Meanwhile the British governed the congeries of princely states, crosscutting sects, occupational units, communities, and held on to decisive power.[2]

India was the largest of Britain's imperial possessions, but the others gave just as much trouble. The inability to reconcile Ulster Protestants to Irish autonomy led to continued violence between the uprising of 1916 and the partition treaty of 1922. Egypt saw nationalist rioting in 1930 and 1935 although Egypt was nominally an independent kingdom and received League of Nations membership. Iraq achieved independence in 1932, and the Kurd-Sunni-Shiite

divisions that have dominated headlines since 2002 took their toll in the early 1930s as well. In mandatory Palestine, Arabs revolted against Jewish migration in 1936, and only appeasement policies in Europe allowed London to deploy the needed troops to quell the uprising, although Britain acquiesced to Arab pressure to limit Jewish immigration at a time when brutal Nazi policies had made the situation of German Jews pure torment.[3]

Given the military and administrative expenses, was maintaining a colonial empire still worth the effort? Of course, a few left-wing protesters aside, Europeans still believed it essential and on several grounds. It testified to strategic supremacy for the metropole despite the armed forces that had to be garrisoned abroad if not actually engaged in endemic fighting. It rewarded a powerful network of elites at home. It promised safe control of vital resources, including petroleum for the British and rubber for the French. The Dutch continued to develop the oil and mineral wealth of their vast Indonesian archipelago. Secured at bargain prices, the bounty of the Third World – oil and rubber and cotton, tobacco, copper and precious metals – compensated for the wartime squandering of wealth in the First. Colonialism also reaffirmed the cultural or 'civilizing mission' of Europeans after the terrible lapse of the First World War. European administrators trained native civil servants, organized education, and selectively interpreted the social and cultural worlds that they sought less to penetrate than to keep under control. The transactions of everyday rule in the empire profoundly influenced the colonized country, but also the colonizers. Young men of the metropole found themselves possessors of an unsettling power that offset the dull daily tasks of rural administration; servants abounded without real cost; and youthful idealists could construct a humanitarian and ethical vocation among their subjects abroad.

It is an open question whether capitalism reinforced or finally weakened the structures of colonial domination. International economic exchange built on and helped to perpetuate the unequal relationships of metropole and colony, the latter as source of commodities or relatively cheap labour. But industrial unrest was a prevalent feature of inter-war colonialism, as indigenous labour, uprooted from a crumbling village structure (as it had been in Europe the previous century), continued to migrate to the mines of Katanga or Witwatersrand, the port of Mombasa (Kenya), the textile factories of Cairo or Bombay.[4]

Since the cause of the working class had also become a major ideological theme of European political activists, these developments created an opposition to colonialism at home. The Second International had condemned colonialism before the First World War. The communist parties took up the issue after the First World War, and it remained one of their fundamental themes until the 1980s, when Soviet armies were mired in Afghanistan. Moscow's own control over its Central Asian, Ukrainian, or Baltic peoples never seemed to involve any of the same issues. The more overseas colonies were integrated into a world economy, the more their fate was caught up in the divisions of domestic politics.

Colonial domination could not have been preserved forever. The French, the British and the Dutch were divided among themselves as to how much self-governance they could encourage. For every far-sighted and cultivated colonial administrator who advocated expansion of

'indigenous' autonomy, there were conservatives whose policy, in the words of one French governor general in Viet Nam, was 'surveillance, punishment, repression'.[5] Still, the system broke down when it did because the colonial powers could not stabilize their own peaceful order after the First World War, and descended toward renewed and even more destructive warfare. The whole structure of inter-war European political reconstruction depended upon a fragile prosperity. Once it fell apart, and once, too, nationalist and fascist regimes came to power in Europe (and in Japan), renewed large-scale warfare would have been hard to avoid. The First World War had already created the conditions for nationalist movements to advance in the colonial world. The Second World War made their rapid success far more likely.

## THE WORLD ECONOMIC CRISIS AND THE VULNERABILITY OF DEMOCRACY

Even before the Great Depression, the more fragile democratic regimes in Europe had already collapsed. The Hungarian revolution of 1919 was suppressed by a military counter-revolution that installed an authoritarian (if nominally parliamentary) regime in that country, so reduced in size by the Treaty of Trianon. Spain and Italy abandoned liberal-democratic institutions in the 1920s; Poland's military began to curb parliamentary power.

But the world economic crisis of the 1930s made democratic prospects far worse. The prosperity of the late 1920s, promising as it appeared, rested on a very fragile foundation and was vulnerable to key policy failures. For it was based on an effort to restore what was an oversimplified interpretation of how the international economy ran before the war. Before 1914, the major world economies had adopted the so-called gold standard, which seemed a prerequisite for membership in the civilized world. The gold standard provided that the subscribing countries' central banks promised to redeem their national paper currency in gold. This meant in effect that no participating country could accumulate significant deficits on current account or pile up import surpluses beyond the values of what it exported or borrowed from foreign investors. If it continually spent more than it earned from abroad, holders of the country's currency and bonds would supposedly worry about the real value of the paper assets they held and would run down the spendthrift nation's gold reserves, supposedly forcing a hike in its interest rates and an offsetting contraction of foreign purchases. The beauty of the system was that it supposedly kept an international equilibrium automatically. In effect the Bank of England was the linch-pin of much international exchange (although the French franc and German mark played large roles in Eastern Europe), and despite vast foreign expenditures, the Bank of England kept the pound sterling at its pre-announced gold value.

The income that Britain received from foreign investment and its positive balance of trade with its colonial possessions, above all India, offset its negative balance of trade with Europe. Returns from outside Britain minimized the deflationary adjustments at home that might be required to maintain the country's extensive foreign investments and confidence in the pound more generally. What is more, London actually could shift the real costs of monetary adjustment onto the countries that held sterling. The

First World War, however, shattered this world, which seemed to guarantee international financial equilibrium so painlessly and automatically, but which in fact was already finding it more difficult to operate without central bank intervention even in the last years of peace before 1914.[6]

The post-war years saw no easy restoration of world trade. Russia, which had been a major purchaser of Central European goods and a provider of grains, timber, and other materials, plunged into the economic misery of civil war, hyperinflation, and isolation. The successor states to the Austro-Hungarian Empire also became a depressed area; the former internal trade of the Habsburg Empire was now fragmented by new frontiers and hostilities. Stagnation meant that urban areas no longer could absorb the excess labour of the countryside. And whereas hard-pressed peasants of Eastern and Central Europe and southern Italy had also migrated to the Americas in record numbers from 1890 to 1914, they could no longer do so after war broke out. In 1924 the United States, caught up in a cycle of xenophobic reaction to its earlier openness, passed the Johnson Act, which virtually shut its borders to Eastern Europeans.

As wartime demand slackened, most economies underwent a short but very sharp recession in mid-1920 and 1921, triggered in some cases by a rapid cut in expenses as states sought to return to normal financial conditions. In 1922, in the United States prosperity returned and the Americans entered a vigorous seven-year expansion. But all industrial economies remained subject to business cycles: vigorous investments and demand usually declined after seven years of expansion.

The problem was even deeper, in fact, because of the war's wastage of savings and capital. During the war, countries had not renewed industrial infrastructures and had indirectly taxed national savings by cumulative price increases through two- or three-fold ablative inflation. Nations had also gone heavily into debt; some of this debt was internal and owed by one citizen or bank to another and thus would be settled by internal redistribution of wealth usually at the cost of those on pensions or rents or other fixed income. But, in addition, Britain, France, and Italy owed significant war debt payments to the United States, while Germany owed reparations to Britain, France and Belgium. Moreover, each country had lost significant foreign assets whose earnings had helped offset the cost of imports: Britain had sold off about 25 per cent of its foreign portfolio. The relatively easy burden of international exchange and debt before 1914 became far more oppressive in the 1920s.

When Britain and other countries 'returned to gold' between 1925 and 1930 (or more precisely adopted a gold-exchange standard where dollars could also serve as a reserve), most felt the need to raise prevailing interest rates in order not to lose reserves. However, the tight money policies of the late 1920s inhibited investment in Britain and exacerbated labour relations in Germany. Britain had revalued the pound at a rate that meant its products were relatively more expensive than those available in or from America, thereby producing an extra burden on its balance of payments. With the United States now a net creditor nation, any American failure to 'recycle' dollars to Europe would add to the deflationary pressures. Americans poured their savings abroad into all sorts of European loans, some for productive investments, others for public amenities. Many of these loans were short-term and had to be frequently renewed. In addition, once the stock market began to climb rapidly at the end of the 1920s, American investors tended to borrow to buy Wall Street securities, not Central European bond issues. Once the American stock market plummeted in 1929–30, with its huge contraction of American wealth (since so many individuals and banks had tied up their credit in the market), American savings were no longer available.[7]

Democratic politics in the new countries of Central Europe was linked to prosperity, which was rapidly vanishing. Over the next three years, unemployment would rise to catastrophic proportions: perhaps over 25 per cent of the work force in the United States and Germany. The national output of countries slumped badly. In Germany and the United States – the hardest hit industrialized countries with reliable statistics – GNP descended to about 60 per cent of 1929 levels by late 1932, at which time the statistics were bottoming out in Britain and Germany. But hard times were spreading to France and Spain.

Although we think of the Depression in terms of industrial unemployment, it brought great suffering as well to rural communities. Vigorous demand and rising prices for agricultural products brought vast expansion of output and then a collapse of prices from 1920s to 1930s. Bumper years sent grain prices skidding in 1927 and 1928; they did not recover in 1929 and as grain suppliers sought to dump their stocks, prices fell to three-fifths of the 1913 level by 1932. Only by the thirties did interventionist governments, whether of the left or nationalistic, introduce national marketing boards that could control sales and pay farmers to curtail output.

The fate of agricultural producers was thus as harsh as those of industrial workers. Since the family farm could not 'fire' its old parents and numerous children, or export its excess young working adults to cities without jobs, it left them to stagnate without shoes, clothes, schooling, medicine, housing, urban manufactures, and even clean water or an adequate diet. Outside Britain and Belgium, industrial countries still retained large rural populations – up to 50 per cent living in areas defined as rural in the United States, about 25 per cent on farms in Germany. In addition, most of the rural population outside Europe, the northern United States and Canada, or coastal and Great Lakes North America was overwhelmingly composed of peasant producers, usually dependent upon costly loans from seedtime to harvest. Hard-pressed farmers switched their political allegiances – many voting Democratic instead of Republican in the United States by 1932, but in Germany defecting en masse to the National Socialists by 1930. The Democrats seemed to promise cheap money and credit, and the Nazis promised security of farm tenure and even higher tariffs and protection than already existed. They also handily blamed Jewish creditors for the woes of farmers.

Other commodities underwent the same passage from boom to bust, and as peasants suffered, political turbulence grew. Coffee bean prices declined by 75 per cent from 1927 to 1931, helping to open the way to the Brazilian dictator, Getulio Vargas. The rubber plantations that had boomed in South-East Asia (as increasing numbers of automobiles spurred the need for tires) saw prices collapse, helping to provoke nationalist resistance movements. The collapse of sugar prices brought misery to Indonesia and hardship to the Caribbean. The collapse of silk prices meant greater

poverty for two-fifths of Japan's farmers, and aggravated the discontent of many Chinese peasants, who would undermine the precarious control of the Chinese nationalist government. The prices of some crops fell dramatically even though demand remained relatively stable: the price of cotton decreased by two-thirds. The response varied: silent suffering or acceptance of wage labour, flight and migration, occasionally open rebellion. American tenant farmers in the southern states, i.e. sharecroppers, dependent for yearly credit on landlords who controlled the payback of 'settle' they finally received, remained in misery and increasingly compelled to switch their peonage into wage labour.[8] African-Americans would eventually accelerate their migration to the industrial cities of the North once urban factories began to revive. Egyptian peasants, also dependent on a cotton monoculture, cut back their consumption of food grains by a quarter.

In South-East and East Asia, the price of rice fell 50 per cent even though consumption hardly fell. The results were rural immoderation in Japan, the rise of prostitution, a new resentment of the city and of recent trends toward liberalization, and a symbiosis of distressed peasants and a belief in the saving role of the military. If German peasants looked to the National Socialists, the Japanese put their trust in militarist values. Where white colonial authorities reinforced local landlords, peasant rebellions were a possibility. Vietnamese peasants revolted unsuccessfully as the authorities sought to collect taxes in the face of collapsing rubber prices. By the end of the 1930s, South Vietnamese landlords had largely supervised a switch from tenancy to wage labour (a trend also underway in the cotton South of the United States), whereas peasant tenancy remained more resilient and resistant in the North. In Burma, continued collection of poll tax payments as rice prices collapsed triggered a rebellion through 1931–1932, which British rulers put down only with difficulty. Whether in South-East Asia, West Africa, the Dutch Indies or the Middle East, the mid-1930s were to prove the point of inflection for European colonial rule. That is, mobilization of labour and peasants and intellectuals that achieved decolonization after the Second World War really 'took off' in terms of organization and protest during the 1930s.[9]

## CONTENDING POLITICAL RESPONSES AND IDEOLOGIES

Such an economic disaster had profound effects on politics. It essentially undercut the progress toward a restoration of liberalism and in many countries undermined the coalitions needed to support democratic government. The United States was an exception. Since the Republicans were in power and persisted in deflation, the voters turned toward Franklin Delano Roosevelt, who did not campaign for radical measures, but whose New Deal still turned toward major social and economic experimentation. The Roosevelt administration profoundly altered government in the United States by enlarging the role of the federal government, which stepped in to provide emergency relief, to organize public works (the Public Works Administration and Works Progress Administration) and to prop up farm prices by instituting limits on crop planting (the Agricultural Adjustment Act). It also put young people to work in public conservation jobs, began huge new natural resource planning and hydroelectric construction (the Tennessee Valley Association), passed a national system of old-age pensions based on compulsory business and employee contributions (Social Security) and eventually gave labour unions the right to organize workers if they won a majority in factory or plant (the Wagner Act). Roosevelt's remedies were often inconsistent, and the Congress remained more conservative. Nonetheless, despite his inconsistency and initial unilateralism, Roosevelt's buoyant politics and oratory shattered the passive helplessness that seemed to afflict the previous Hoover administration. By 1936, the Democrats became the majority party, holding the support of the southern states they had had since the Civil War, and gaining for the first time the votes of urban blacks, many farmers, labour unions, small businessmen and a critical number of patrician bankers and industrialists – a combination that kept the presidency in the hands of the Democrats for twenty years and made Roosevelt the first president to win a third and then a fourth term. Other coalitions, in Sweden or later the so-called Popular Front in France, pursued similar policies. But Roosevelt became a symbol par excellence of a popular and democratic response first to economic hardship and then to the rise of Fascism and Nazism.[10]

The stakes seemed very high. For in fact, the dominant trend did not seem to be that of the left, but the illiberal right. The appeal of fascism emerged out of the First World War, or even before. Nationalists stressed that military conflict was a fundamental condition of modern society; countries were locked in perpetual rivalry; politicians talked and talked, but soldiers solved problems. The notion of military saviours was not far away in the 1920s, and hard-pressed monarchs might appoint military dictators. Faced with growing civil strife between left and right and a move toward republicanism, the Spanish monarch appointed a military strongman, Primo De Rivera, in 1923, who governed for eight years by a sort of implicit social bargaining before being discredited by corruption, the continuing war in Spanish Morocco, and encroaching economic stagnation. Until his popularity ebbed, Primo was one of the first military saviours of the inter-war although they had appeared frequently in nineteenth-century Spain and Latin America. However, it was in Italy, Germany, and Austria where the most spectacular transformations occurred.

Mussolini organized his Fascio di Combattimento in 1919, on the basis of soldiers' camaraderie and their yearning for radicalism. The movement prospered in the Po Valley between 1920 and 1922, as it teamed up with landlords to smash the newly militant rural labour unions. As the parliament became paralysed between old and new parties, the King named Mussolini prime minister in late October 1922 (Plate 24). For two years, he ran an administration that hovered between dictatorship and a sort of manipulated party clientelism. By 1925–1926, however, he had opted for single-party rule and was transforming the ideology of fascism into a glorification of the all-powerful state and party, which must organize unions and businesses into government-sponsored 'corporations'. The opposition was driven into exile, sometimes imprisoned, or sentenced to a sort of village confinement in remote areas. A secret police, political tribunal, press censorship, glorification of the party, subjection of parliament, and claims to educate a new Fascist man made the Italian experiment a qualitatively new sort of

regime – one the Fascists themselves liked to call 'totalitarian'.[11]

By totalitarian, Mussolini meant originally that Fascism claimed the totality of political power – no other party was to exist, although in fact the other parties continued a harassed and minority existence until they were pressured to dissolve in the mid-1920s. As the regime stabilized and the term was also later applied by many European and American scholars to Hitler's Third Reich and Stalin's Soviet Union, it became even more encompassing, and suggested that the single party and the leader it glorified organized not just politics but society as a whole. The ruling party was intended to reshape the economy, education, and sports, to control the media, theatre and culture – in brief, not just suppress outright opposition and democratic institutions, but organize an all-controlling regime and society in which individuals found fulfilment through a regimented public sphere. It was this claim that was the real novelty of the inter-war period, and perhaps of twentieth-century politics in general. It was a fundamental rejection of the belief in the individual as the basis for government; henceforth it was to be the nation or the racial community, or the proletariat (and its agent the party). Liberalism was allegedly weak, talky, outmoded. The economic crisis supposedly confirmed that it had failed.

Mussolini's regime was hardly totalitarian at all in comparison to Hitler's, who required only a year to consolidate the dictatorial control that Mussolini had needed five years to build. The stability of the German Republic (known as the Weimar Republic) founded after the defeat in the First World War remained hostage to prosperity. The new regime was widely, if unfairly, blamed for the terms of the Treaty of Versailles, and it also seemed totally dependent on the deals among the political parties. When adverse economic conditions made it impossible for the Social Democratic Party that represented much of the organized working class to find a common ground with the representatives of the industrial community, the parliament was paralysed, and Reichspresident Paul von Hindenburg had to resort to rule by decree. Voters defected to Hitler's National Socialist Party, which had seemed doomed to extinction in the mid-1920s but secured 20 per cent of the vote in the September 1930 Reichstag elections. Continuing parliamentary paralysis made the party increasingly popular, and by the summer of 1932 it collected almost 40 per cent of the electorate. After growing violence in the streets and some unsuccessful efforts to find a chancellor who could alleviate unemployment and win back votes, Hindenburg was prevailed on by short-sighted conservatives and civil servants to call on Hitler as the head of a coalition cabinet on 30 January 1933. Within two months Hitler had built the first concentration camps (Plate 25), exploited the arson of the Reichstag building (probably an independent action) to arrest the Communist Party deputies and limit freedom of the press, allowed his Storm Troopers to boycott Jewish shops, introduced legislation to 'restore' the civil service – i.e. to fire Jews from government office including the educational system (Plate 26) – and finally to browbeat the Reichstag deputies to pass a constitutional amendment, the so-called Enabling Act, that gave him virtually absolute power for five years. Within a year, he would abolish the state legislatures, abolish all parties but the National Socialists, pull Germany out of the long drawn-out disarmament conference in Geneva, and win a resounding

plebiscitary approval for his policies. When President Hindenburg died at the end of August 1934, the army allowed Hitler to accumulate the power of chancellor and president as the self-proclaimed Führer.

The Italian Fascist regime and the German National Socialists shared much in common, but also had significant differences. Both movements stressed the role of the party in running the state. Both leaders had been spiritually reborn by war; Mussolini had broken with the Socialist Party in which he had made his pre-1915 career as a radical editor to take up the notion of the war as revolution and then to organize would-be radical soldiers into a *fascio*, or militant movement whose name suggested the unity of determined individuals bound together. Hitler had realized that war would give him his vocation. A young Austrian who saw his aspirations to be a great artist frustrated, Hitler was fulfilled, indeed exalted, by his military service in the German army. When he was gassed near the end of the war and then internalized the humiliating defeat, he understood that he must now live for politics directed against the flabby civilian governments and the socialists and Jews that had allegedly betrayed the country. Here was a key difference from his Italian counterpart. Nazism had anti-Semitism at its core even if over the next years Hitler might also scorn alternative parties, castigate the feckless republic, its parliamentary system and the craven compromises on reparations. Both leaders remained convinced that nations could remain vital only by virtue of war, that they were locked into a Darwinian struggle for survival, that politics must ultimately be based on unremitting conflict (a notion that tempted many theorists in the inter-war period), and that as leaders they had the personal mission to inspire and organize the masses. Mussolini, however, found his allies among the nationalist intelligentsia that emphasized the role of law, not liberal law, but the state. He retained his title as 'head of government', that is, an appointee of the monarch, and he restored the prerogatives of the Catholic Church. Hitler stressed (and found the allies to agree) that the German People, were more fluid and more encompassing than the state and its officers and that they spoke through him, so that ultimately the Führer was the source of law.[12]

## SOVIET POLICIES AND POPULIST MOBILIZATION OUTSIDE EUROPE

It is little wonder that many Western intellectuals – horrified by watching a cultivated Western nation wilfully turn its back on human rights, do away with a liberal republic, and turn toward savage values – felt that liberal democracy was impotent, politically as well as economically. Some political activists and intellectuals believed that only communism could solve the crisis of liberalism and stand up to fascism by nationalizing economic resources and embarking on a thoroughgoing state planning. While many on the left remained within the parties of democratic socialism – from whom the communists had split after Lenin came to power in Russia and whom the communists denounced in the late 1920s and early 1930s as 'objectively' helping the fascists – others believed that only the hard discipline of the Communist Party could bring about transformation. The politics of toughness and sometimes secrecy was allegedly necessary on the left, if it was not to prevail from the right. The Communist Party had

consolidated power in Russia by progressively stifling other parties and then independent voices. Even under Lenin, the party had moved to exert total control; but the system became far more repressive by the 1930s.

Stalin managed to emerge at the top of the party by adroit alliances, first by taking sides against the Bolsheviks he denounced as too radical and impatient, then by turning against the earlier allies that he now claimed were too gradualist and complacent, even condemning Leon Trotsky – the outstanding leader along with Lenin of the revolutionary period – as a traitor to the Bolshevik project because he did not accept the idea of subordinating the project of international revolution to constructing a socialist order 'in one country'. In the mid-1920s, Stalin had warned against over-ambitious nationalization of village lands; now in 1928, he decreed moving beyond the NEP (the New Economic Policy was a retreat from war communism that allowed the resumption of small private enterprise, foreign investment and the retention of private peasant lands) and forcing the peasants into collective farms. Peasants resisted but, over the course of a year and a half, local communists applied pressure so that they would faithfully troop to the local authorities and place their land either in the nationalized plot (the Sovkhoz or state farms) or the local cooperatives (Kolkhoz, or collective farms). Their animals were also taken, as were tractors and other implements. To orchestrate this vast renunciation of individual holdings the party started a campaign against allegedly wealthier peasants, the Kulaks, who could employ farm labourers and were supposedly dedicated to bitter counter-revolutionary resistance. The rallying calls of the hour became 'dekulakization', 'the Kulak as the bitter adversary and rapacious rural creditor'. Above all in the Ukraine, where resistance to the Moscow regime remained strong, the party moved into high gear, cutting off supplies and contributing to widespread famine. Bukharin would incur Stalin's later revenge by suggesting that peasants would produce more in response to market incentives, but the party leadership would then have remained subject to the resistance of this huge social group.[13]

No sooner was the collectivization campaign underway than Stalin introduced the first of several Five Year Plans; an ambitious and rapid effort to increase industrialization. The NEP vanished in the cities; property was taken over, vast numbers of rural workers were forced off their land and into the cities, where they laboured intensively to build factories, the Moscow subways, hydroelectric plants, the iron and steel industry of the Don Basin, new Siberian centres of industry. Gigantic projects became the order of the day. Much of this, too, was inefficient, and a great deal rested on semi-coerced labour especially of the youth organization or Komsomol.[14] But at a time when Western economic output was falling sharply, and the misery of unemployment raged, the Soviet Union underwent an industrial transformation of unprecedented rapidity. Communists and left-wing intellectuals in the West could boast that while capitalism was finished, Soviet communism was transforming Russia, unemployment was unknown and the economy was leaping ahead.

Any real achievements, however, came at the cost of political freedom. The party embodied the wisdom of history, and it, in turn, depended upon the wisdom of the leader, its First Secretary, Comrade Stalin, increasingly the recipient of adulation, who guided a worldwide movement,

resisted fascism and redefined political theory and culture. And into this world of total control – so appealing to many Western intellectuals, so devoted to history and higher purpose, and potentially the only force to stop Nazism – came a fantastic series of political upheavals in which, orchestrated by Stalin, the party turned on its own vast membership, discovered and denounced plot after alleged plot, and through a series of show trials, first of alleged plotters against the Leningrad Party, then supposed wreckers from the factional fights of the 1920s (Bukharin and Trotsky), and finally against half the army command (accused of being in league with the Germans abroad). No one knows how many party members were expelled, arrested and ultimately shot. Millions were sent to the forced labour camps, the gulags, where the toll taken by cold and disease remained very high.

Faced with this phenomenon, Western interpreters took the concept that the Italians had themselves coined – totalitarianism – and applied it to those aspects of the dictatorial experience of the 1930s that Fascism, National Socialism and Stalinist Communism had in common: the role of the party, glorification of the leader, the use of terror and arbitrary arrest to destroy solidarities and 'atomize' the population, and planning for war. Like all typologies, 'totalitarianism' subordinated specific differences among the experiences to which it was applied: the extermination of the European Jews found no parallel in the Soviet Union, nor did the latter regime ever indulge in the plans for widespread conquest that motivated Hitler. Later historians, perhaps reacting against the Cold War era idea of totalitarianism – made famous in Hannah Arendt's volume *The Origins of Totalitarianism* – would suggest that totalitarianism was less total than originally depicted, that interstices of private life, inner opposition and culture might exist, that rule was fragmented and often inefficient. These observations are correct, probably more correct for Germany than Russia, and most correct for Italy. Nonetheless, the totalitarian experience of the 1930s was one of the defining moments of the twentieth century – a moral extreme that (along perhaps with the later Cultural Revolution in China) seemed a nightmarish culmination of history.

Outside Europe, the Fascist and Soviet experiences found admirers who thought they could borrow selected elements from the new European movements. Chinese politics remained in disarray, eight years after the declaration of a republic and displacement of the Manchu Dynasty in 1911. Revolutionary authority quickly passed from the ideological leader of the revolution, Sun Yat-sen, to General Yuan Shikai, who manipulated the last vestiges of imperial authority in Beijing, as well as claiming the mandate of the new revolutionary parliament; but Yuan died in 1916. When outraged students in Beijing marched against the feebleness of their regime on 4 May 1919, the country they sought to mobilize was fragmenting under their feet. The north of China soon disintegrated into competing warlord jurisdictions, while Japanese forces retained footholds in the former German colonies in Shandong as well as railroad centres of Manchuria, and even for a while in the coastal region of a disintegrating Russia. Back in China and based in Canton (Guangzhou) in the south, Sun Yat-sen turned to Soviet advisers and reorganized the Guomindang (Chinese Nationalist Party, KMT) along lines deeply influenced by Soviet party practice. But the KMT included diverse factions and interests. After Sun's death, his successor, the organizer

of the new Whampoa military academy, Chiang Kai-shek, initially continued the communist collaboration and reaffirmed Sun's venerable 'Three People's Principles' that stressed nationalism, democracy and socialism. Between 1925 and 1928, Chiang Kai-shek came the closest he would ever be to transforming the KMT into a national revolutionary force, winning control in the south and central coastal China, establishing his capital at Nanjing, and finally turning on his own unprepared communist collaborators (Plate 27). By 1928, the KMT ejected the Beijing warlords and completed their takeover. The remnants of the erstwhile Chinese Communist Party (CCP), who had, as Stalin consistently urged, collaborated with Chiang until the end, remained in disarray, until finally in the mid-1930s, they migrated to a new regional stronghold in Yenan and reoriented their strategy around Mao Zedong's concept of peasant revolution.[15]

Nationalist and populist political mobilization was thus a far broader experience in the 1930s than just its German or Italian manifestation might suggest. Not all of it was totalitarian; even in Japan the encroachment on civil liberties and dissenters depended less on a well-formed ideology of state or party power than intimidation by zealots and the slow stifling of opposition. Nationalist strongmen embarked on heroic modernization as in Turkey. Populists, often from the military, attacked the entrenched elites of wealth and privilege in the name of the people in Latin America. Lazaro Cardenas, president of Mexico, restored the lustre of the institutionalized revolution and its party (the PRI) by listening to country folk at the grass roots and then nationalizing the British and American oil companies. In Brazil, where the federal states retained a good deal of authority, the state governor Getulio Vargas seized power in 1930, as the precarious power sharing of state magnates broke down under the impact of the disastrous fall in coffee prices. By 1938, supported by Brazilian fascist 'Integralistas', Vargas dissolved the congress and declared a 'New State', a title that the Portuguese military leader Salazar had shortly before invented to describe his own authoritarian coup. Vargas's new constitution, while never fully implemented, nonetheless entrusted him with total power as President of the Republic.

In Argentina, the developing middle classes managed to secure a decade of liberal (radical) rule through the 1920s, only to have the earlier oligarchic elements – generals, ranchers, bankers and clergy – seize power in 1930. The military took over in 1943, and the most talented of their number, Juan Peron, built a new populist movement in symbiosis with the labour unions of Buenos Aires.[16] These populist leaders mobilized working classes and the poor (the *descamisados*, or shirtless ones, in Argentina), threatening liberal newspapers and the parliaments and parties traditionally controlled by entrenched and privileged elites. The Latin Americans sometimes claimed to emulate the Fascists, and they sought to distance themselves from the United States. Indeed, a similar movement led by Governor Huey Long emerged in Louisiana in the 1930s, only to be cut short by his assassination. Wherever they arose, such movements testified to the discrepancy between parliamentary forms, which remained under the control of wealthy and powerful elites, and the reality of vast social and economic deprivation. Authoritarianism allegedly on behalf of the people thus remained (and remains) a recurrent political temptation for ambitious and demagogic leaders.

## ORIGINS OF ANOTHER WORLD WAR

By the late 1930s, therefore, all the bright hopes of the League of Nations, of internationalism, of tolerance and liberalism, were sputtering to an end. Only a decade and a half separated the last military echoes of the First World War in the eastern Mediterranean (1922) from the Marco Polo Bridge clash between Japan and China (1937), which opened the East-Asian theatre of the Second World War. An even briefer six years separated the treaties of Locarno (1925), which seemed to ensure peace in Europe, from the Manchurian takeover by Japan that defied the principles of the League of Nations (1931). This period (shorter than the wars in the ex-Yugoslavia) marked the brief moment, in which it appeared that 'collective security', as embodied in the League of Nations, might be feasible.

Collective security in the inter-war years did not have the same connotation as the concept later adopted from 1949 to 1989, when it referred to the NATO alliance against and the Warsaw Pact and a perceived Soviet threat. Inter-war collective security meant that all nations in the League should come together if one of their number or a country outside demonstrated aggressive behaviour. It was more fluid and ad-hoc, yet this beautiful dream also proved hard to put into practice. By the 1930s, it was clear that some countries, pre-eminently Japan, Italy, and eventually, Nazi Germany, had expansionist designs. The first breach of collective security took place in Asia, where the Japanese military, still aspiring to a hegemonic role in northern China, became alarmed by Chiang Kai-Shek's advance toward Beijing. Japanese units had established their 'dominant' power in Manchuria by 1910, and they remained involved in warlord politics after 1911, and during the 1920s. As renewed claimants to power in Beijing and North China challenged Chiang Kai-Shek's claims to authority, the Japanese occupiers across the wall continually intervened, finally seizing the excuse of intervening to prevent local clashes that threatened the railroads to seize control of the Manchurian provinces in 1931 and then to reorganize the vast industrialized areas into a Japanese protectorate, named Manchukuo. The Chinese Government had little choice but to accept the *fait accompli*, and while the League sent a mission to investigate and deplored the action, it took no concrete counter-measures. Japan responded to the sanction by simply withdrawing from the international organization.

The intervention had decisive influence within Tokyo as well. The Japanese Government was divided between liberal and nationalist leaders. While the liberals included cautious military officers and admirals, and there were civilians among the nationalists, increasingly it was the military establishment that formed the backbone of the nationalists. The death of the Taisho Emperor (1912–26) and elevation of the young Hirohito (known by his official name as the Showa emperor, 1926–89) marked a difficult period for Japanese liberalism (Plate 28). The second half of the decade saw a series of rival party cabinets and leaders, who were unable to effectively organize the new potential for mass democracy, which seemed primarily to generate corruption and inside deals. The collapse of rice and silk prices (perhaps two-fifths of peasant families grew cocoons) during the Depression was disastrous for the rural economy. Rural impoverishment and the rise of prostitution as a recourse for hard-pressed peasant families, many of whom also had

menfolk in the military, meant a reaction to the liberalism and democratization of the previous decade and a call for patriotic virtues. The Manchurian adventure gave the rising militarists at home a stronghold outside the jurisdiction of Tokyo, and there was always the danger of a coup at the periphery should civilians try to limit the army's role. Tension increased and right-wing officers felt justified in taking up the weapon of assassination, following the example of young Samurai officers in the turbulent transition of the 1850s and 1860s, and by the fanatic who attacked Hara in 1921. In attempted coups of May 1932 and February 1936, the prime ministers were assassinated.[17]

The programme of expansion was renewed in 1937, as Japanese troops exploited a clash with Chinese soldiers at the Marco Polo Bridge near the border of Manchuria to launch a rapid invasion southward. Japanese forces moved swiftly, but were only partially successful. They rapidly took the coastal strip of China, indulged in a brutal occupation, and when they arrived at Chiang Kai-Shek's southern capital of Nanjing carried out an orgy of brutal killing of Chinese prisoners and civilians – perhaps up to 300,000, while the delegates of Western powers, who as a legacy of their own special status, observed from their extra-territorial enclave. However, Chiang Kai-Shek's government retreated into the interior with a capital at Chunking and some provisioning via the 'Burma' road into British held territory. A stalemate prevailed, and the Japanese had to contemplate a more extensive war than originally conceived.

Such a war would probably entail a collision with the West. To justify expansion, the Japanese leaders recommended uniting Asians against colonialism in a Greater East Asia in a co-prosperity sphere, although the blessings of liberation they were bringing to the Chinese invalidated the concept. It was clear that the United States, with bases in the Philippines for at least another decade, sympathized with China and would resist accepting Japanese hegemony in the western Pacific. With its colonies of Hong Kong and Singapore and its role in Burma (Myanmar) and India, Great Britain was also a potential foe even if London feared a war in Asia at a time when the German menace was growing in Europe. Another possible enemy was the Soviet Union, with its long Manchurian frontier, as well as memories of Japanese occupation of its far eastern territories during the Russian civil war, and the war they had fought over Korea during 1904–05.

Faced with Chinese resistance and the hostility of the Western powers, the Japanese had to make difficult choices. At this point, international rivalries became crucially important. For the Japanese army, a collision with the Russians seemed the greater danger or the greater opportunity. Did it not make sense to take advantage of the apparent turmoil that the vast purges suggested might be underway in the Soviet Union to strike pre-emptively? Japanese probing actions against the Soviet and Mongolian border region, however, were badly pummelled in 1939 by the Russians at the large clash at Nomonhan, which suggested a large attack would not be easy. Moreover, the German-Soviet non-aggression pact of August 1939 meant that the Japanese could not count on the Soviet's having to fight a two-front war. After Hitler's attack on Russia on 22 June 1941, that situation drastically changed, but by that time the Tokyo government was also reorienting its objectives. The Tokyo government secured its own neutrality pact with Moscow in April 1941, and advocates of continued

expansion to the south urged their case. The Imperial Navy especially looked to a wider war in the south; Japan lacked the oil for its expanded fleet. It was imported from the United States and the Dutch East Indies, but if these sources were cut off, then conquest of the Indies might be the only recourse. Such a manoeuvre would involve war with the British, the Dutch and probably with the Americans as well. As of 1938–39, these alternatives were unresolved and indeed still somewhat theoretical. Americans were still far from involvement, committed largely to neutrality, enraged by the atrocities in China, but with a relative handful of primitively armed troops in the Philippines or Hawaii hardly prepared to constitute a serious threat. But the time for decision was approaching. The German-Soviet non-aggression pact, the subsequent outbreak of war in Europe and the adverse fortunes of the Allies – with the conquest of the Netherlands and France, and the siege of Britain – American rearmament and fleet expansion and its control of steel and oil supplies, were soon to make Japanese choices all the more acute. The one option that might have spared Japan an expansion of conflict – a retreat from China and return to the regional pacts of the 1920s – was, however, precisely the choice that military control of policy-making precluded.

Manchuria and the visible ineffectiveness of the League would have important ramifications in Europe. Collective security was a weak reed. Hitler decided that he would not be bound by its constraints. In *Mein Kampf*, the book he dictated during his brief imprisonment after the unsuccessful Munich coup of November 1923, Hitler had outlined a vision of a vast 'living space' (*Lebensraum*) in east-central Europe, where German settlers would rule a population of Slavic peasant subjects. Only a few non-Germans believed that a German Chancellor would actually cling to such a brutal and megalomaniac vision. Hitler's advent did not seem to radically escalate German ambitions, but in December 1933, he demonstratively withdrew from the long-standing disarmament parleys at Geneva on the pretence that the French would not agree to equality of arms. By March 1935, he announced that Germany no longer considered itself bound by the military clauses of the Treaty of Versailles; the country would activate a conscript army (to fill out the cadres that had already been planned) and build a military air force.

How should the West react? The underlying dilemmas of the new order resulting from the Versailles Treaty, based as it was on keeping Germany safely disarmed, emerged with painful clarity from 1934 to 1936. To go to war over an announcement of restored German military sovereignty seemed excessive. The European left still believed in disarmament, the new generation of youth seemed deeply pacifist, still disillusioned by what seemed the pointless sacrifice of those now in their thirties and forties. If France would not disarm, why should Germany not be allowed to restore its own forces? France, Italy, and Britain convened at Stresa to declare that they would cooperate to resist any German aggression, but their response amounted to little. For a few years after 1935, the French and British would still retain a preponderance of force. Hitler had vast ambitions, but he was not mad; he understood what was feasible and what was not. If there had been a firm Anglo-French policy of deterrence, it might have restrained his behaviour or – so Germans secretly reported over the next years – led the generals to remove their Führer rather than

be forced prematurely into a disastrous war. But in fact, neither London nor Paris was willing to sustain a policy of firmness.

The precariousness of the Versailles Treaty became even more apparent, therefore, when Hitler announced in March 1936 that he would no longer observe the strictures against garrisoning the demilitarized zone that extended from 50 km (30 miles) east of the Rhine to the French border (Plate 29). Hitler assured his nervous generals that Paris and London would not act, and he was right. The British opponents of resistance argued that the territory, after all, was German, and French policy-makers, desperate to avoid war, were happy to defer to London. Each appeaser drew support from the other.[18]

Diplomacy and possible deterrence of Hitler became additionally hostage to paralysing conflicts between ideological systems. On 6 February 1934, right-wing squads and pro-fascists marched on the French Parliamentary Palace across from the Place de la Concorde and had to be dispersed by gunfire. Their mobilization was followed the next day by a massive demonstration of the left-wing supporters. Just six days later, the Austrian Christian Social Party – increasingly authoritarian in orientation and seeking to hold its own against the competition of a pro-fascist Fatherland Front – forcibly suppressed the Social Democrats, shelling the apartment complexes that housed the Viennese working class and imposing a quasi-dictatorial regime.

The new Spanish Republic, voted into power in 1931 with high hopes, was also torn between left and right. After a Republican victory in municipal elections, Alfonso XIII, discredited by his long reliance on the military dictator, Primo de Rivera, departed into exile. The left-wing coalition – including the Republicans, led by the newly chosen president, Manuel Azana, the socialists, and the delegates from the Catalan and Basque regions in quest of decentralization – introduced a new constitution providing for autonomy statutes for the Catalans and the Basques, and a secularized school system, which aroused the hostility of the Catholic Church. However, the coalition was unable to agree on a land reform programme. Agrarian radicalism, organized by the powerful anarcho-syndicalist trade unions (CNT), which refused political cooperation, continued to seethe. Facing mounting problems, and dissolving from within, the left-wing coalition was voted out of power in 1934. The new centre-conservative government delayed the reforms in progress and tried to undercut the concessions to the autonomous regions, helping to provoke what proved a very ill-advised revolt by the populist leader of the socialists, the northern mine workers, and Basques and Catalans who feared they would lose their newly promised autonomy. The government flew in troops from Spanish Morocco, suppressed the revolts, arrested thousands and seemed prepared to execute harsh reprisals – a policy that in turn galvanized a new left-wing re-emergence around the issue of amnesty and organized to halt what they depicted as a slide toward fascism. This new left-wing coalition – the so-called Popular Front – emerging in both Spain and France with Stalin's blessing from afar, now included, alongside socialists and the liberal left, the communists. The Popular Front thus responded to fears of fascist advance at home and (as discussed below) to the Soviets' calibration of the Nazi threat of war.

The ideological confrontation taking place in Spain was also helping to transform European international politics,

as were issues of imperialist politics. During 1934 and early 1935, Mussolini in fact still appeared to offer London and Paris a potential ally against Germany, especially since he originally feared Nazi designs on neighbouring Austria. But this divergence of the dictators was not to last. Mussolini coveted empire, and by autumn he was exploiting a border conflict between the Italian colony of Eritrea and the Ethiopian monarchy as a pretext for possible conquest. Haile Selassie, the young emperor, appealed to the League. The British and French cabinets sought to arrange a partition scheme but it aroused popular rejection at home when its details leaked out. When the Italian invasion of Ethiopia finally began, London and Paris reluctantly had to agree to the sanctions that the League voted. These remained ineffective; oil was not on the list of products prohibited to Italy, and Mussolini moved quickly with bombs and poison gas against the Ethiopians, who fought bravely but were soon subjugated. Mussolini learned that Hitler would support his aspirations, and in the autumn of 1936, the two dictators announced the Rome-Berlin Axis. In return, Mussolini accepted Germany's annexation of Austria a year and a half later.

France, Britain, and Italy might have formed a plausible counterweight to Germany until 1935. Even France and Britain alone might still have counted on their joint deterrent capacity until after the occupation of the Rhineland. Hitler had already startled his possible adversaries by removing the danger of Poland's inclusion in an anti-German alliance by signing a non-aggression pact with Warsaw in 1934. For the realistic French foreign minister, Louis Barthou (unfortunately assassinated with the King of Yugoslavia in 1934), only an alliance with Russia could effectively contain Hitler. The Soviet regime was distasteful, but so had been the Tsarist regime before 1914. Stalin, too, became preoccupied by the rise of a German regime ideologically dedicated to eradicating Bolshevism. His foreign minister, Maxim Litvinov, became the most eloquent spokesman for collective security at the League of Nations at a moment when the West was abandoning the concept.

In 1935, at the Seventh Congress of the International Communist, the Soviets announced an important change of policy: henceforth communist parties throughout the world would be encouraged to cooperate with 'progressive' elements of the bourgeoisie and the Social Democrats they had hitherto condemned as lackeys of fascism. For the elections coming up in France and Spain, a broad Popular Front coalition promised to oust the right-wing and potentially pro-fascist regimes.

Although the left as a whole did not substantially increase its vote in the two divided polities, the new coalition allowed the Popular Front to triumph in the Spanish parliamentary election of February 1936, and in the French vote in June. In both countries, the political situation seemed particularly tense and violence could easily erupt. The rallies and strikes in France following the June elections convinced many right-wing voters that the country was on the verge of revolution.

In Spain, extremists on both sides of the political spectrum were resorting to political assassination. After increasing violence in the streets between rightist and anarchist political squads, four leading Spanish generals and their confederates in numerous Spanish cities staged uprisings on 18 July, not all of which succeeded. Burgos and northern Castilla, outside the Basque Country and the

Asturian coal region, passed to the insurgents or Nationalists. In Madrid and Barcelona, Andalusia and Aragon, Loyalists initially prevailed, although a rapid ferrying of troops from Morocco quickly secured Nationalist control of Seville and southern Andalusia. In the areas controlled by the leftists, a wave of revolution broke out after the Nationalist uprising. Throughout the summer and autumn, revolutionary committees carried out rural collectivization and wildcat takeovers of factories, but the exuberance of anarchist collectives lasted for no more than a year. The communists were zealous in suppressing their would-be rivals as Trotskyites, and together with centrist Republicans and moderate socialists took over for the long task of defending republican territory. The government's appeal for international aid was largely rebuffed, except by Mexico and the Soviet Union. Russia provided assistance and helped organize the International Brigades, a major force of sympathetic volunteers, many communists in exile from Germany and Italy, others from the United States, who were sent to augment the Republic's army and fought until late 1938. The new Popular Front French Prime Minister, Léon Blum, contemplated sending assistance, but he was unwilling to act unilaterally as the British refused to intervene arguing that they did not want the war to spread. Instead, Britain took the lead of patching together a non-intervention agreement supposedly designed to preclude all outside intervention or aid. Nonetheless, Italy and Germany were willing to supply the insurgents with air power and trained pilots. Madrid became the first city to experience sustained air bombardment, in November 1936, and German squadrons destroyed the Basque town of Guernica in the following year. The civil war lasted almost three years and cost the lives of half a million (of the 25 million) Spaniards. Over the long run, the Nationalists prevailed, slowly conquering more territory, ultimately splitting Barcelona from Madrid, and forcing hundreds of thousands over the Pyrenees in early 1939. Franco took power in the name of the Falange (itself a mixture of would-be fascists and Catholic traditionalists) and the Navarre Carlists, a far-right political party and militia (Plate 30). Spain slipped into two decades of repression and stagnation, its regime surviving the defeat of the fascist powers in 1945 because Franco kept the country out of the Second World War despite Hitler's insistence.

The Spanish Popular Front perished in civil war, while in France, the movement petered out from its own contradictions. A triumphant left-wing majority came to power in June, bringing to office a Jewish Socialist prime minister, Léon Blum, who admired Roosevelt and sought to institute a programme of wage hikes, paid vacations, and reformist measures. The right-wing opposition hated the coalition, and some of Paris's fashionable young intellectuals began to dream of Fascism and Nazi activists. The ruling coalition soon succumbed to disagreements. The moderate Radical Socialist Party of the provincial middle classes had joined the coalition to win the elections, but they hardly warmed to socialist causes, and when the communists unfurled the red flag or sang the International they had second thoughts.

As the new government took office, a massive wave of sit-down strikes shook the country. Blum summoned industrialists and union officials to sign a collective-bargaining agreement that raised wages, recognized the unions and mandated a forty-hour week and paid vacations.

The government nationalized the Banque de France and indulged in a rhetorical fusillade against 'financial feudalism'. Although Blum inherited a milder version of the European depression, joblessness was nonetheless preoccupying, and he sought a Keynesian reflationary solution involving public spending. But the government – still committed long after the British and Americans had ceased to maintain the gold value of the franc – faced capital flight. Blum finally did have to devalue; he also declared a 'pause' in his legislative programme and finally sought exchange controls to halt the export of capital. Rebuffed by the upper house of the parliament, he resigned in 1937. A new cabinet, now led by a Radical Socialist politician devoid of reformist inspiration, led the majority. Blum would return briefly in the spring of 1938 as Hitler annexed Austria. Henceforth his task was to try and rally a less partisan government for the sake of rearmament. Indeed he had nationalized the fragmented aircraft industry and his energetic aviation minister encouraged new production, but conservatives refused to cooperate until the remnants of the Popular Front were dismantled. The consequences went far beyond France, as possible projects for colonial reform in Algeria and above all Indochina were placed on hold. In the metropole, another Radical Socialist, Georges Daladier, now prepared to distance his party from their earlier cooperation with the parties and unions of the working class.

By 1938, the governing coalitions in the Western democracies had in effect long abandoned the concept of collective security and were unwilling to entertain any alternative but trying to satisfy Hitler's demands and hoping that he would be satisfied by reuniting the German peoples of Central Europe into his Reich. The French would not act without the British, and under Neville Chamberlain, the British Conservative majority was committed to settling German grievances by the policy they defined as appeasement. In March of 1938 when the leader of the Austrian Christian Socialists tried to organize a plebiscite to demonstrate that his country wanted to remain independent, Hitler marched into the neighbouring nation to great acclaim and organized a vote that showed overwhelming enthusiasm for forced integration into Greater Germany (so-called Anschluss). Hitler himself was clear that at some point war would come with the Western powers and continued his 'four year plan' of military build-up. By late spring of 1938, he turned his attention to Czechoslovakia, where the country's three million German speakers (originally from the Austrian Empire) were being stirred up by local Nazi supporters who claimed that Prague was imposing intolerable restrictions on their ethnic identity. Hitler seemed to be threatening to go to war. British emissaries and the press suggested separating the ethnic German Sudetenland from Czechoslovakia and allowing it to unite with Germany. The Czech Government headed by Eduard Benes could have forced France at least to honour treaty commitments and go to war with Germany if it had insisted on taking up arms, but fearful of being abandoned, the Czechs finally consented to the deal that Chamberlain insisted on negotiating with Hitler in late September and October 1938 at the conferences held in Bad Godesberg, Berchtesgaden, and Munich. Stalin himself sensed that Britain and France were deeply reluctant to confront Hitler as he withdrew the International Brigades from Spain and in the next year would consider his own arrangement with Germany.

Chamberlain presented the Munich Agreement as a great triumph. He had preserved the peace, and Hitler had assured him that he had no further claims in Europe. The Labour opposition and, just as important, the opponents of appeasement in his own party were less sure. In any case, Hitler – taking advantage now of Polish and Hungarian designs on those portions of Czechoslovakia inhabited by their irridenta as well as of Slovak demands for autonomy – moved into Prague in mid-March 1939. He annexed Bohemia and Moravia as a 'protectorate' within the 'Great German Reich' and allowed the Slovaks their own dependent state. Chamberlain reluctantly concluded that Hitler could not to be trusted to keep his word, and the British extended guarantees to Poland and Romania. Chamberlain's apologists claimed that appeasement had won the West a year to rearm, and indeed both Paris and London accelerated their rearmament. But Hitler was also arming further, and the resources of Czechoslovakia were now lost to any Western coalition.

The major question was the stance of the Soviet Union, and on this issue scholarly debate still continues. Stalin had clearly lost interest in Popular Front collective security by late 1938. Stalin could justifiably conclude that the French and British had no serious interest in an effective military alliance with Moscow. Deep into the summer of 1939, they showed no urgency in part because they discounted the efficacy of the Soviet military forces after the purge trials and probably in part because of ideological blinkers. By the spring of 1939, Stalin dropped his foreign minister Litvinov (who as a Jew was offensive to Berlin) and was exploring negotiations with Germany. He continued to pursue them even as, by the summer of 1939, the British and French – who consistently underestimated the Soviets' military capacity – desultorily began to approach the Russians. Hitler could offer more than the Western Allies, however: one-third of Poland and perhaps a free hand elsewhere in Eastern Europe; and on that basis the Non-Aggression (Ribbentrop-Molotov) Pact of 23 August 1939 was concluded, permitting Hitler to attack Poland a week later (Plate 31). Ostensibly the friction arose over the issue of Warsaw's ill-treatment of Germans in the Polish Corridor, but the immediate goals were the recovery of Danzig (present-day Gdansk) and the conquest of Poland. The Germans staged a border incident to justify their invasion of Poland on 1 September, and Britain and France responded with a declaration of war on 3 September.

## THE SECOND WORLD WAR

The Second World War dwarfed the First in its extent and its destructiveness. The line between civilians and soldiers, which had still been largely observed in the First World War, was virtually erased. The Nazis used the SS as well as units of the army to pursue genocidal policies in their areas of conquest, attempting to annihilate all the Jews of Europe (they managed to kill about 6 million of Europe's 11 million Jews, several hundred thousand Roma and Sinti, large numbers of homosexuals and people with disabilities, and many Russian and Polish civilians, as well as thousands of reprisal victims in the West). The air war increased in destructiveness: German bombers had been used with increasing devastation against Madrid and Guernica in the Spanish Civil War in 1936, against Warsaw in 1939, against Rotterdam in 1940, and then with great destruction against London, Coventry and other targets in the Battle of Britain in 1940. By the time the Anglo-American forces began their bombing offensive, they used hundreds of four-engined bombers on city targets and killed tens of thousands in Berlin and Hamburg and other German cities, culminating in 35,000 dead in Dresden (February 1945), and, in Japan, with perhaps 100,000 dead in the great Tokyo incendiary bombing. Approximately 150,000 lost their lives when the atomic bombs were dropped on Hiroshima and Nagasaki. Since the war effort depended on civilian production facilities, it was believed that such civilian casualties could be justified. Wartime famine conditions killed millions in China and even in British-held Bengal.

By the time the war ended, some 60 million people had perished from war-related causes. Populous urban centres were devastated, food production was curtailed, and millions of refugees displaced to wander across Europe. The Russians paid the heaviest toll and lost perhaps 25 million soldiers and civilians. The Jewish communities of east-central Europe had been liquidated. And in a final chapter about 12–15 million Germans were driven from the recovered Czech Sudeten land and the formerly German territories of East Prussia, Pomerania and Silesia (awarded to the Poles, who had lost the eastern borderlands they had disputed with the Soviet Union since the First World War). Perhaps 3 million ethnic Germans died in these 1945 upheavals, along with about 600,000 killed in air raids on German cities, 4 million soldiers and another 2.5 million who never returned from military captivity, a heavy price for their earlier enthusiastic support for Nazi policies. In Asia, up to 15 million Chinese may have died in famine and flooding and military-related operations; the Japanese sacrificed about 2 million of their soldiers and perhaps 400,000 of their civilians to bombing, against which they had no adequate defences. Perhaps a million Indians died in the wave of refugees who poured back from conquered Burma, and at least another million in the Bengal famine. Half a million Vietnamese perished in the famine of 1944. Even when famine did not kill millions outright, the misery of cold and hunger (as in the Netherlands in the winter of 1944–45, or besieged Leningrad) carried off infants and the elderly and imposed mass misery. Major cities of Germany, Japan and western Russia, along with Warsaw, Budapest, Manila and dozens of other urban centres, lay in ruins. The railroads, bridges, ports, and factories of Italy and northern France were devastated.

The war can best be understood as four interlocking conflicts. The first was the Anglo-French war to resist German hegemony in Eastern Europe, the war that was triggered by Hitler's invasion of Poland and, in effect, was a resumption of the conflict of 1914–18. This war ended with Hitler's conquests of Norway, Denmark, the Low Countries (the Netherlands, Belgium and Luxembourg) in April and May 1940, and then the capitulation and occupation of France, and the removal of all British forces from the continent a month later. This was what has been described as 'the last European war'[19]. Britain was left to carry on the anti-Hitler battle on the North African front and at sea on the North Atlantic.

The second conflict was the major ideological war of the Soviet Union (in coalition with the Americans and the British) against Hitler. This war was started when, after a period of uneasy neutrality in Eastern Europe, Hitler

reverted to his long-held hostility to Soviet Communism and to his old aspirations for *Lebensraum* and invaded Russia on 22 June 1941. In the number of troops engaged, the savagery of the fighting, the German disregard of traditional restraints on violence and killing, the heroic intensity of the Soviet armies and industrial effort, this struggle was unprecedented. The turning points were the Russian defence of besieged Leningrad for almost three years, the halting of the Germans before Moscow in December 1941, and the German defeat at the end of the six-month combat for Stalingrad (from July 1942 to February 1943). This was the war that saw the largest land battles along a front almost 2,000 miles long, and vast civilian casualties, including the large-scale Jewish liquidations. Until the Anglo-American forces invaded Italy in summer 1943 and then, with larger forces, occupied France in June 1944, almost all the fighting took place on the Eastern Front, although the United States provided increasing amounts of materiel to both Britain and Russia through its Lend Lease Programme.[20]

The third conflict was the East Asian war, starting with the Japanese invasion of China in 1931 (if not Manchuria six years earlier), but expanding in scope with the Japanese decision to invade South-East Asia – including Burma, Siam, Indochina, the Dutch East Indies, and the Philippines – in a series of lightning attacks in December 1941 and early 1942. It was the Japanese attack on the US naval base in Hawaii (Pearl Harbor) on 7 December that finally incited President Roosevelt to overcome the divisions of American public opinion and to bring the country into war. Although American positions in the Far East were overrun and lost, in the long run the economic potential of the country and its capacity to rebuild its navy as well as a vast air force meant that the Japanese wager on a rapid conquest was fruitless.

Tokyo's calculations still remain puzzling in some respects, for the balance of material resources doomed their enterprise. Japanese policy-makers decided that American demands to withdraw from China were unacceptable, and they hoped that if they conquered the oil resources they needed and established a defensive perimeter, the United States would seek a settlement.[21] Although they rapidly overran much of the region, the British and Americans continued to hold southern New Guinea and fought over the next few years to reconquer the islands of Micronesia and eventually the Philippines and island bases that enabled them to launch massive air bombardments of the Japanese home islands. Japan might well have surrendered without use of the atomic bomb in August 1945, but there was strong bureaucratic momentum to use this new weapon once it had been developed, and the Tokyo leadership tried to negotiate for a less drastic outcome. Moreover, the Americans were impatient for surrender; the American General Staff clung to its predictions that an invasion of the home islands would be necessary and would be very costly if Honshu and Tokyo had to be taken by ground forces. The

Japanese were divided about surrendering until the very end and responded to the final ultimatums with enough reservations to let the impatient Americans go ahead with their programme. By this time, area bombing by massed bomber fleets with great civilian casualties had long become a matter of course.[22]

The fourth conflict involved what might be called 'the war of succession' in the areas occupied by Germany and Japan, that is the war of resistance movements against the occupying forces and the collaborationist governments or pro-Axis elements that collaborated with them in France, Norway, Greece, Yugoslavia, Poland and the occupied portions of the Soviet Union. Similar struggles took place in Japanese-occupied South-East Asia. This fourth conflict was thus a war of partisan armies and savage reprisals, which tended to rage in 1944–45 as it became clear that the Germans and Japanese would lose the struggle underway. Essentially it was a war to decide which elements would rule once the Germans and Japanese were forced to surrender. In France and Italy the diverse political forces within the Resistance – communists, Catholics, non-communist socialists, leftist democrats, and even traditionalist and Catholic nationalists – largely cooperated. However, in Greece, Yugoslavia, and Poland, communists and non-communists divided (and most momentously, perhaps, in China) and often ended up in a civil war within the civil war that divided both resistance coalitions from the collaborators and occupation forces.

Stalin and Churchill conferred in November 1944 and informally agreed that the West would have pre-eminent control (90 per cent) in Greece, while Russia might determine events in Romania, with Poland and Yugoslavia being split 50-50. Whether on this basis or not, Churchill helped the pro-Royalist resistance forces disarm the communist guerrillas, while in most of Eastern Europe, the pro-Soviet groups were supported in their rise to power. Thus in Eastern Europe and China and Viet Nam the last stages of the Second World War merged into the opening phases of the Cold War and national anticolonial struggles.[23] Even as millions of soldiers and the populations of the occupied and combatant countries experienced immense relief at the end of the immense war, new political and military struggles emerged in the colonial world and Eastern Europe.

It was remarkable that dreams of national reprisal and vengeance, which had so poisoned democratic politics and international relations after the First World War, played no significant role after the Second World War. In that sense, the old exaggerated aspirations of nationalism and domination among the European powers and Japan had burnt themselves out. It was now the turn, however, for long-nurtured ambitions to nationhood to emerge among the colonial peoples. So, too, the victory allowed aspirations for ideologically motivated regional hegemony to manifest themselves among the largest post-war powers: the Soviet Union, China, and the United States. Struggles over empire had not yet ended.

# THE END OF EMPIRE AND THE TRANSFORMATIONS OF THE INTERNATIONAL SYSTEM

*Charles S. Maier*

## DECOLONIZATION

The end of the Second World War completed the transformation of the imperial systems. Although nationalist political leaders, among them Charles de Gaulle and Winston Churchill, aspired to keep control of their country's empires, this was to be a vain dream, and the efforts to renew or prolong colonial domination proved costly and often bitterly divisive at home. In Africa, the French did crush one major uprising with great bloodshed in the Aurès Mountains, and they reclaimed authority in North Africa and South-East Asia. But the colonial peoples, who had seen the Japanese overrun European possessions in South-East Asia, understood that their rulers were not invincible.

In post-war struggles those who remained loyal to the colonial powers felt abandoned to the local revolutionary forces when their former rulers finally yielded independence. 'Betrayal' of those who had remained loyal to their rulers remained a poignant theme that Westerners defending their role in Asia and Africa would evoke from 1941 until the American helicopters left Saigon in 1975. The Japanese had themselves posed as liberators of the territories they occupied from colonial rule and had found collaborators in the Philippines, Burma, and within the Indian National Army. But instances of cruelty and heavy-handed rule soon provoked resistance movements. National movements, however, such as the Vietminh, who emerged to fight the Japanese, were hardly willing to acquiesce to colonial rule once again. Moreover, the United States stood in theory behind the decolonization movements, or at least did so while Franklin D. Roosevelt was alive before the development of the Cold War.[1]

Although Prime Minister Churchill was an inveterate believer in Britain's imperial role, the permanent officials in London and the new Labour Party government (elected in July 1945) believed that Britain should seek to exercise its post-war role through indirect means. The country was financially depleted by the war as many of its remaining post-war assets had to be liquidated to pay for the struggle. It had granted its colonies in the Middle East and India extensive credits in London (the so-called sterling balances,

which in theory remained as liabilities that might be withdrawn) as it drew on their resources to fight the Pacific War. Lend Lease shipments ceased with the end of the war, and a $3.75 billion line of credit for the post-war era from the United States was negotiated conditional upon London's promise to make sterling freely convertible and to dismantle the protectionist agreements negotiated between the wars with other members of the British Commonwealth. Britain had to exercise influence rather than power, and the structure of colonial rule was thus to be transformed into a more associative arrangement.[2]

Britain, however, ruled many areas of mixed ethnicity and religion that threatened to descend into intercommunal violence when granted autonomy. Rioting and mob violence in the 1930s had already provided a foretaste of possible future events. The Arab uprisings of 1936 had led London to try to limit Jewish migration at a period in which Jews were being harassed in Europe. In India, the leader of the Muslims in the Congress, Ali Jinnah, insisted on a separate state for Muslims, and although Gandhi resisted, Nehru accepted the bitter medicine. With a self-imposed deadline of 1 January 1947, a frontier was hastily drawn – but in fact members of each community lived on both sides of the line, and the days of independence brought mob mayhem and killing as Hindus and Muslims tried to flee to their respective countries.[3]

The British, caught in the intractable conflict between Zionist aspirations and Arab interests handed the future of the mandate in Palestine back to the United Nations, which after President Truman finally resolved to support the scheme, voted for a partition into two states in the fall of 1947. The Jewish communal authorities accepted the plan. Arabs and Palestinians were determined to resist, and war between Palestinians and Jews on the territory of the mandate began and climaxed with the initial victory of the Jewish armies over the Palestinians between March and May 1948. When in mid-May the British mandate over Palestine formally ended and the Israelis declared the independence of the Jewish State of Israel, the neighbouring Arab states invaded the new country. After coming close to military catastrophe, Israel successfully defended the territory, and following truces in late spring and summer,

expanded the originally envisaged frontiers by the 1949 armistices. The successive phases of the war proved humiliating and catastrophic for the half or more of the 1.4 million Palestinian inhabitants of the territory, who fled their homes under instructions from Arab propagandists or were expelled by Israeli forces – the reasons are contested – during the course of the fighting.[4]

At the same, Britain relinquished its formal residual hold on Egypt, Iraq, and Transjordan even while military and financial advisers helped maintain a shadow influence. London was not yet ready to quit Malaya, where it faced a dogged communist independence movement during the so-called Emergency. For another fifteen years, it would not have the resolution to divest itself of the middle African countries where white 'settler' minorities still counted on Britain to prolong their control (Kenya, Nigeria, Rhodesia). And finally, it would have to prepare to leave the countries of West Africa, the Gold Coast and Nigeria, where it also left a legacy of hostile ethnic groups – the Hausa North and the Yoruba and Ibo South – confined within borders that the dominant groups wanted to preserve.

For all the vexation of imperial divestiture, the British withdrawal still seemed easy compared to the French situation.[5] Between the wars, the French Right had envisioned the 'valorization' of the empire as a way to retain a threatened great-power status, and the Vichy regime of 1940 carried on this aspiration. On the other side, Charles de Gaulle, as leader of the Free French challengers and, by 1944–45, provisional president of the new Fourth Republic, also wanted to preserve as great an overseas French role as possible. Meeting in Brazzaville in late January 1944, he and pro-Free French officials envisaged the formation of the French Union, which the reformers planned would federate the colonies and embark on their industrial development, while the traditionalist administrators insisted it would assimilate their populations without independence and preserve the political and cultural primacy of the metropole. Félix Eboué, a socialist of West Indian origin and governor of Guadeloupe, and Henri Laurentie, who advanced a sophisticated scheme for a federal assembly in which all members of the French Union were to be represented, were the major advocates of the new ideas, which collided with the conviction of most administrators and military that France's 'civilizing mission' and goal of 'assimilation' meant firm control. Shifting politics in Paris and the resistance of military officials and some colonial administrators precluded application of the more liberal interpretations, although it is unlikely that in the long run these would have satisfied nationalists. The transition in the states of French West Africa remained perhaps the happiest exception due in part to the stature and intellect of African leaders who could merge ideals of 'negritude' with the universalist aspirations that the French republican tradition offered. But the long-term evolution of all the African states would face grave difficulties, and the responsibility of the colonial state for economic setbacks and authoritarian outcomes in the decades after independence will be long debated.[6]

In the states of Indochina, the Japanese ended the formerly residual French administration in March 1945, after the Vichy regime had collapsed at home, and encouraged supposedly independent regimes. Gaullist forces resolved to reassert sovereignty, envisaged again a French Union that would cede 'appropriate' (*propre*) internal autonomy but maintain control of external relations in the hands of Paris

and its Governor General. Roosevelt did not support this goal, but he disappeared from the scene a month later. In August and September as Japanese authority collapsed, the Vietminh took control in the North during 1945, but France reoccupied the area around Saigon. French-Vietminh negotiations began in 1946. Ho Chi Minh was willing to readmit French troops in order to oust Chinese forces that might otherwise never leave. While a Vietminh delegation went to Paris to negotiate, fierce clashes, provoked certainly in part by the local French military forces, broke out in Haiphong in November and Hanoi in December. The ensuing struggle lasted eight years.[7]

The situation in Indochina introduced the French, and later the Americans who took over the struggle, to a new type of warfare that military theorists on both sides analysed as revolutionary or guerrilla war, in which the enemy were absorbed into the local population in the presence of French soldiers, but returned to reassert control of the population when the foreigners departed.[8] Such a war – as in Greece or Yugoslavia during the German occupation – was a struggle to control the local population. In Indochina, and later in Algeria, the French officers believed that the majority of the local population did not support the liberation movement, but had to be protected. The Vietminh, later the FLN (Front de Libération Nationale) in the south, were supposedly extremist, their analysis went, and famous for their ruthless violence. Instead the French proposed to set up a government under Bao Dai that would opt for union with France, but they vastly overestimated the legitimacy it might possess. Increasingly the French Right suggested that all these movements were part of a communist conspiracy to undermine the West. Indeed Ho Chi Minh was a Marxist as well as a nationalist, and committed to a communist victory. The arrival of the Chinese communists at the Viet Nam border in 1949 reinforced this sense of a life and death struggle against international communism. However, the trouble was that in fact the countermeasures taken drove more and more of the youth into the camp of the nationalist forces. The French in fact lost finally in a major conventional siege and battle in north-east Viet Nam when their troops were besieged at Dien Bien Phu. A new premier, Pierre Mendès-France, promised peace in forty days or vowed to send in a mass of conscripts and not just smaller forces of professional soldiers, and a deal struck at Geneva in 1954 divided the country at the 17th parallel. But already both sides were preparing for the next stage. The peace provided for elections in the South; Northern Vietnamese communists were seeking to infiltrate and control the elections, and the Americans supported postponement. The scale of the fighting increased in the South until the Americans had committed half a million troops. Only in 1973 would a peace agreement be negotiated.[9]

Paris had long since extricated itself from Indochina and its other colonies. Mendès-France had acceded to Tunisian self-government and the transfer of power to the long-standing nationalist movement, the Neo Destour of Habib Bourguiba. Demands for Algerian independence were another matter, however. Neither Premier Guy Mollet, a socialist, nor other centrist forces, who held power after the next parliamentary elections, were prepared to capitulate in Algeria, which the French defined as an integral part of the French Republic and included a million French settlers, who had made the cities of the coast their home. But even as

the end of the war was being celebrated on 8 May 1945, in Europe and Algeria, nationalist demonstrations provoked a massive repression by the French military in Sétif and the Constantine region, which left between 15,000 and 40,000 Muslim casualties and hampered any future gradualist settlement. By the early 1950s the Resident General was determined to meet uprisings with forceful counter-measures including the destruction of villages harbouring rebels. As in Indochina, the French were convinced that the National Liberation Front (FLN, a term that would be used in Algeria and then by the insurgents in South Viet Nam after 1954) was unrepresentative of the native population they considered loyal. The FLN began to strike with bombs at European gathering places in the city of Algiers, and civilians became the true hostages of the struggle. The French applied counter-terrorist doctrines, destroying the rebel cells in Algiers, regaining apparent control of the Kasbah by using torture to interrogate captured FLN soldiers. They won 'the battle of Algiers' by 1957, but could not win 'the battle of the frontiers'. Supported by the Egyptian government of Gamal Abdel Nasser and lodged across the border in Tunisian 'sanctuaries' the FLN could be pursued only by indiscriminate air strikes,

such as the bombing of the hospital at Sakiet Sidi Yousef in February 1958, which threatened in turn to trigger a UN debate, where the Americans might have felt compelled to join in a condemnation of Paris policies.[10]

Without American support, the colonial powers just could not persevere in resisting anti-colonial uprisings. When Washington believed that nationalist forces were communist agents of Moscow, they usually lent assistance but not at the cost of a possible direct military confrontation with Russia or China. As late as 1954, President Eisenhower and his chief of staff contemplated using a nuclear weapon to help the French avert defeat in Indochina. Although he accepted the Central Intelligence Agency's plans to help overthrow the communist strongman of Guatemala, Eisenhower had the good sense to decide against Paris's desperate request.

Moreover, by 1955, the emerging ex-colonial nations, sponsored by a China now seeking to distance itself from Moscow, and likewise by India and Indonesia, and including oil-rich Arab lands, gathered at Bandung to coordinate their policies as a cohesive bloc of 'non-aligned' powers. Washington did not appreciate their neutralist stance, but the State Department did not wish to seem aligned with a

retrograde policy of defending colonial positions. In the autumn of 1956, Guy Mollet, who was angered at Egyptian assistance to the FLN, and Prime Minister Anthony Eden, who was determined to reverse Nasser's recent nationalization of the Suez Canal, colluded with Israeli leaders to plan an invasion of the Sinai Peninsula, supposedly rescue the Canal from Egyptian mismanagement, and overthrow the ambitious Egyptian leader. But the American Government decided that this policy could not be allowed to stand. It disavowed its NATO allies, and at the very moment the Soviets threatened to use missiles if necessary against Britain and France, Washington decisively applied pressure, including a threat to the British pound sterling, and compelled London and Paris to back down. The Suez reversal completely undercut Eden's domestic position and caused a deep moral crisis in London, where defenders of residual British power felt humiliated and betrayed by their major ally. It also suggested to Paris that if America turned hostile, they could not prolong their struggle in Algeria even if they seemed to be winning.[11]

These difficulties caused the uneasy coalition governments in Paris to fall apart. The conservatives and Catholics would not accept yielding control of Algeria to the FLN while increasing numbers of the centre left and the socialists were unwilling to escalate the pursuit of the rebels. In an effort to retain a majority, the government sought to offer partial reforms and autonomy, which proved too grave a concession for the right wing and insufficient to satisfy the rebels. Settlers and generals, who feared Paris would capitulate in May 1958, seized power in Algiers, formed a committee of public safety, dropped paratroopers on Corsica, threatened to land in Paris and prompted even socialist deputies to accept the return to power of General de Gaulle, who had retired from public service twelve years earlier (Plate 32).

De Gaulle won massive support for a new constitution that sharply curtailed the power of the legislature to overthrow cabinets and endowed the president of the Fifth Republic with far greater authority over international affairs and legislative initiatives. As new president, however, de Gaulle quickly came to realize that France could not win the Algerian war. From the settlers' adulation, he incurred their wrath, had to face down a new attempted *coup d'état* in 1961, and subsequent assassination attempts by irreconcilable conspirators, and finally, by 1962, signed the Evian Accords that allowed the FLN to govern Algeria.

The Dutch, who had hoped to recover 'the Indies' and overthrow the Republic of Indonesia that nationalist leaders A. Sukarno and M. Hatta had declared upon the surrender of the Japanese, abandoned their ambitions slowly. At first, they relied on the British and Anglo-Indian forces in the theatre, and then re-established themselves on the eastern islands. An armistice painfully ratified by March 1947 envisaged a United States of Indonesia under the Netherlands crown, which would federate the nationalists' republic based on Java and Sumatra with an East Indonesian State to remain controlled by the Dutch. The armistice, which faced opposition in both camps, unravelled a few months later as the Dutch decided they should exploit their 100,000 soldiers stationed so far from home and embarked on a police action that reconquered much of Java. A further agreement signed in January 1948 on the USS *Renville* also failed to hold. Events moved toward a chaotic climax as Islamic and communist challenges to the Sukarno-Hatta leadership emerged within the republic,

while Dutch forces sought to organize a federal state throughout the archipelago. Sukarno gained American support by suppressing the communists. When the Dutch embarked on a second police action at the end of 1948, occupied the republic's capital and arrested the Sukarno government, the Americans lost patience and threatened to suspend Marshall Plan aid. It was easier to put pressure on Amsterdam than on Paris, and Sukarno's nationalist movement – in contrast to the Vietminh – had proved itself staunchly anti-communist at a time when the Cold War was becoming disturbing. Unable to prevail outside the major cities in any case, the embittered Dutch ceded control of all but West New Guinea, which was yielded as West Irian only in 1962.[12]

With the early 1960s, one might end the history of the overseas colonial empires. The Indians annexed the small Portuguese enclave of Goa in 1961. The Belgians precipitously abandoned the Congo Republic in the face of nationalist resistance in 1960, although not without attempting (with CIA aid) to support a secessionist movement in the province of Katanga with its important copper mines still controlled by the Union Minière. Britain had granted the Gold Coast independence as Ghana in 1957, and Nigeria followed in 1960. London's plans to federate the departing colonies, whether in the federated states of Malaysia, the West Indies, the Central Africa Federation or Southern Arabia, lasted only a few years: each dissolved into national states upon or shortly after gaining independence. Nigeria, a federated unit since 1914, underwent a long and cruel civil war, but remained a conglomerate nation. Only a few Portuguese redoubts remained in Africa, and the Portuguese army, tired of the fruitless battles in Angola and Mozambique, revolted in 1974, to end the authoritarian regime at home and terminate a senseless war.[13]

For the former colonial powers, the end of empire brought often-immense political recrimination at home, although only in France and in Portugal did the conflicts bring down a regime. Nationalist Europeans felt their sense of national mission and historical status diminished. Soldiers who had tried to win the hearts and minds of loyal collaborators felt they were being forced into betraying them. Liberal colonialists were grieved that their lofty projects for economic development and political education were now to be interrupted. In the context of the Cold War, many feared the advance of communism. Yet, the conditions were hardly catastrophic for the metropolitan societies. The money invested in colonial enterprises did better in fact than domestic investments. Advocates of decolonization understood that their own 'civil war' – that is, the Second World War – bore a major responsibility, and that control over such distant peoples could not be perpetuated. In fact, they often learned to keep influence by indirect means; agreements with the new Algerian Government allowed Sahara oil to be exploited by France; the Union Minière kept its properties in the Congo. The British continued to train the armies of the Middle East; the promising students of West Africa came to Paris, while those from South Asia went to London and Oxford. Families seeking work gravitated from the former colonies to the cities whose language they had learned and adopted, eventually, in effect, to transplant their communities, cuisines, and cultures of the so-called 'Third World' into the cities of the former colonial powers. Europe was

prospering, more consistently than in any other period of its history, and in that post-war economic growth and the ideological exertions of the Cold War, and in the new ideas of integration – through the Marshall Plan, the Coal and Steel Community, the European Community – a new sense of Europe was born. But only reluctantly and slowly would its citizens recognize that they had to integrate as their neighbours those who had once been their subjects.

As for the former colonies, they gained the independence which almost every citizen believed was the prerequisite for their society's advancement. Westerners told them that it profited not to gain national independence if their new native rulers suppressed human rights that were better guaranteed under the colonial powers. Even Washington statesmen argued that the rule of the Communist Party over the citizens of Russia was far more oppressive than governance by colonial officials. For the indigenous peoples of the Maghreb or Central Africa or Asia, such a calculation was usually beside the point. Wisely or not, intellectuals and simple tribesmen alike believed that collective self-determination was the foundation for all other rights. They moved from being subjects to citizens. The measures for local representation, which Paris or London schemes had offered from the Government of India Act in 1935 to the Algerian Loi-Cadre Deferre of 1956, always resisted that basic grant of national self-determination. On the other hand, the indigenous governments that took over after independence often succumbed to bitter internal rivalry, military dictatorship, and ethnic strife. The institution the colonial powers had trained most effectively was the military, whose leaders often emerged with the sense that they alone might speak for the national interests of their new country, or that they alone would be free from corruption and clientelism. The era of colonial rule had left arbitrary national borders that did not coincide with tribal lines, but leaders resisted any changes lest all frontiers be thrown into contention. Nigeria's vast expanse, for example, included at least three different basic cultural areas and rivalry enough to provoke a tragic civil war. Even where partition accompanied independence, as in South Asia, inter-communal violence remained high. High expectations of economic development were often frustrated as governments sought to institute prestigious building projects, implant industries that lacked a market infrastructure, and control food prices to still urban protest. The models of state socialism attracted many intellectuals in Africa and India throughout the 1960s, even as they resisted adaptation to the world market. Foreign companies still controlled mineral wealth or petroleum resources. *L'Afrique noire est mal partie* (Black Africa in Trouble) was the title of one apt study of the 1960s.[14] Politics disappointed many intellectuals. Arab leaders yearned for unity but generally could not institute pluralist governments at home. Vast and voluble India divided into cross-cutting communities of faith, class, and region, preserved government by discussion but remained ransom to vast reservoirs of poverty and village under-development. The British had re-infused its many jurisdictions with the notion that a common state could provide the possibility for letting its fragmented people preserve political identity.

Historians and political leaders debated the so-called legacy of colonialism. Was it an unmitigated evil like Conrad's *Heart of Darkness* on a huge scale, in which arbitrary power necessarily blighted any initiative taken?

Were those who led struggles for liberation all revolutionary heroes, as students in Paris or Berlin claimed in their 'tiers-mondisme' of the 1960s and 1970s, even if they then surrendered to self-aggrandisement, grandiose and impoverishing developmental schemes, and arbitrary power? Colonial rule had withheld decisive political responsibility: it had not allowed local assemblies to educate a new parliamentary class; it allowed the native best and the brightest to study philosophy in the metropole, but not to practice politics. It trained officers, intellectuals, and civil servants at best, but not party leaders. Defenders of the system had always argued that some day the colonial world would be ready for self-government, but that day was always in the future – and then one day, it was at hand. The rise and fall of overseas colonialism were one of the most important, if not the most essential, developments of world history in the century from approximately 1870 to 1970, and it is hardly an unblemished story.

## The Cold War and a divided world

Decolonization played out against the growing polarization and tension of the Cold War. The United States and Britain on the one side, the Soviet Union on the other shared the objective of defeating the Axis, but had different visions for the future, even if both sides invoked the term democracy. Critical divisions began to emerge already before the end of the Second World War. The Russians grew suspicious at the West's waiting so long to open a Second Front in north-west Europe. Americans and British grew fearful that Moscow wished primarily to impose one-party rule on the areas of Europe its armies swept into.

Still, the months of impending and accomplished victory in 1945 brought hope for a new post-war order that culminated in the founding conference of the new United Nations organization at San Francisco from April through June 1945. Arduous allied negotiations had produced a plan for a General Assembly that was to include all fifty participating countries and a Security Council to address urgent questions of war and peace and would comprise five permanent members, the USA and USSR, France, Britain, and China, each with a veto right, plus a rotating representation of other states without vetoes. Collective security was a major strand of Franklin Roosevelt's hopes for the post-war world; the emerging UN was, in effect, his monument, and the spirit it incorporated marked the work of its major agencies (including UNESCO) and the ongoing discussions that led to the Declaration of Human Rights by 1947. For all the disappointments and divisions that would follow, the idea of an international civil society based on political and social rights remained a normative summons to global hopes for peace and freedom.

But difficult post-war issues had already emerged. Faced with potential discord after military victory, Roosevelt attempted to secure the basis for post-war cooperation at the Yalta Conference in February 1945 (Plate 33); the Russians won strategic concessions in the north-eastern provinces of China (Manchuria) bordering the Soviet Union as a price for promising their entry into the Pacific War three months after the end of the European war, a commitment they met to the day (which turned out to be two days following the destruction of Hiroshima). A compromise was patched together to overcome the rival

governments that both sides had sponsored in liberated Poland. The reinstated Warsaw government would be based mostly on the Russian-sponsored Polish committee of national liberation, although one quarter of its members would be drawn from the Polish government in exile that had so antagonized Stalin by refusing to accept his frontier demands and accusing the Soviets of executing thousands of Polish officers in the Katyn forest, a charge that was indignantly denied but turned out to be accurate. The new government in Poland, as elsewhere in Eastern Europe, was to be subject to free elections. Eastern Europeans would later complain that Yalta amounted to a condominium in which Washington abandoned the liberty of their region to Moscow in return for a free hand in the West. In fact, Roosevelt and Churchill felt that they could wrest no more satisfactory a settlement given the presence of Russian soldiers up to the Elbe River.

Washington and London grew alarmed when throughout 1945 and 1946 communist elements resorted to intimidation and violence against the pro-Westerners in Romania and Poland. The agreement reached at the Potsdam Conference of July 1945, which provided for occupying Germany as a united country and drawing reparations from its industrial plan, also broke down such that inter-allied cooperation became virtually inexistent. The British and Americans feared Russian subversion of any new all-German institutions; they were frightened by the evident conformity the Russians were imposing over their own zone through a new Socialist Unity party. The Russians and Anglo-Americans also quarrelled over Iran – both sides were scheduled to leave that country, which they had jointly occupied during the war – but the Russians were supporting communist secessionists in Azerbaijan province and withdrew only after Truman threatened a major crisis. The Russians also distrusted American control of the atomic weapon. The American offer for internationalization of nuclear production (the Acheson-Lilienthal Plan) proposed US atomic disarmament but only at the end of a long process in which other countries placed their production facilities under international control. As presented to the UN by American negotiator Bernard Baruch, the plan further demanded that the Security Council veto be set aside in enforcement issues. Soviet nuclear research was well enough underway not to have to accept what Moscow considered an asymmetric US proposal. And, on the other hand, it was probably utopian to expect that American authorities would surrender what they considered the ultimate resource of their nation's post-war power.[15]

Tension grew also in East Asia. The occupation of Japan did not give rise to the same conflict between the former coalition partners since Washington had rejected the last-minute Soviet request for a zone of post-war administration. Japan's future as a non-military, but crucial, American security partner with a unique fusion of liberal parliamentary and bureaucratic politics emerged out of General MacArthur's proconsular role in helping to shape post-war institutions. After a resurgence of left-wing and labour protest in 1947, MacArthur reined in economic restructuring. Organized labour would negotiate extensive employee security provisions, but only at the firm, not the national level. A Marxist intellectual culture would remain strong, and student protests against the close ties with Washington would shake the political scene in 1960, but

this opposition in effect remained only perpetual opposition.[16]

The future of China was troubling, but neither Moscow nor Washington could shape the outcome of that massive struggle. The conflict between nationalists and communists, barely adjourned to meet the Japanese threat, was bound to resume. As the Japanese moved toward surrender, Stalin signed a treaty with Chiang's government in return for strategic and railroad concessions in Manchuria and a Chinese guarantee that Mongolia could subsist as an independent state. A strong state run by Mao Zedong (whose peasant-oriented revolutionary mission had already clashed with the disastrous Soviet wager on collaboration with Chiang in the mid 1920s) was not likely to grant the same concessions, and the Soviet leader placed first priority on establishing a clear-cut sphere of territorial security. Moscow would consistently urge restraint on Mao even as the Civil War resumed and the Communists enlarged their areas of control. Meanwhile, the United States, which had unsuccessfully urged a mediated solution in the Marshall mission of 1946, watched as Chiang's control of China disintegrated under his miscalculated efforts to seize immediate military control in Manchuria and the North, endemic corruption, and advancing hyperinflation with its destruction of a money economy. By 1948, the Communist forces moved to open battles and won a striking series of military successes in central and then southern China.

As the Nationalists fled to Taiwan, and Mao announced the establishment of the People's Republic on 1 October 1949 in Beijing's Tiananmen Square, the Truman administration seemed initially inclined to accept history's verdict and to leave 'Formosa' to its own defence. But the commitment of the Republican Right to 'free China', the intensity of Cold War politics, and the intervention of the PRC in the Korean War precluded a simple policy of disinterest. Instead the 'loss of China' became a domestic issue, and the 'old China hands' in the State Department were scapegoated by Senator Joseph McCarthy and other Republicans, even as General MacArthur called for enlarging the Korean War to China itself, using atomic weapons, if appropriate.

As for the new Chinese regime, isolation and the devastation of the country he inherited led Mao to solicit a thirty-year treaty of friendship and aid with Moscow in February 1950 even at the cost of renouncing claims to Mongolia. The Chinese secured an aid package and the help of Soviet technical advisers. The treaty could hardly be the last word, however. If a smaller Yugoslavia (albeit aided by the United States) could defy the Soviets, a huge China could not be a predictable ally. But for the next years with the Cold War at its height and an open war in Korea from June 1950 until July 1953, the latent tensions between Moscow and Beijing remained subordinate to a sense of ideological common cause.[17]

If Washington moved hesitantly toward an anticommunist stance in East Asia, it had already become deeply committed to the policy of 'containment' in Europe. While Stalin and his advisers found the Truman administration less committed to conciliation and cooperation than Roosevelt seemed to have been, the British and Americans perceived a Soviet threat to impose unchecked Communist Party control in what Moscow described as the peoples' democracies of Eastern Europe and to drive pro-Western leaders from any influence in that

region. The behaviour of each side confirmed the other's fears. At his famous speech on receiving an honorary degree at Westminster College in Fulton, Missouri, in March 1946, Churchill declared that an 'iron curtain' was descending over Europe. It became the West's metaphor for the next four decades.

The ambiguous political agendas of 1945–46 – when in France and Italy in the West, and Poland, Hungary and Czechoslovakia in Eastern Europe, communist and non-communist power sharing still seemed possible – ended by mid-1947. Communists and their affiliated trade unions were either rebuffed or decided on a resolute opposition in the West. In Central and Eastern Europe, members of agrarian and popular parties were tried, imprisoned, sometimes executed, and the significant socialist parties painfully split over the issue of collaboration in so-called peoples' fronts that their communist allies would dominate.

In Greece, outright civil war began, provoked in part by a dubious 1946 plebiscite confirming the monarchy, then encouraged, not really by Stalin, but the Yugoslav communist leader Josep Brodz Tito, whose resistance to Moscow's discipline would make him a hated heretic in Kremlin eyes by 1948 and an ally of opportunity for Washington. When in February 1947, the British told Washington they could no longer subsidize the Government of Greece's struggle against communist guerrillas, the US president enunciated the so-called Truman Doctrine, which provided for assisting countries under attack by armed subversion. However, Germany was the major issue. With lack of unity, uncertainty about reparations, and inability to agree on a monetary reform, the economy continued to languish. After a frustrating Council of Foreign Ministers session in Moscow, the US president announced that Washington was prepared to help any regime fighting armed subversive groups. In June 1947, American Secretary of State Marshall proposed that the United States would provide cooperative European regimes access to what would amount to about $13 billion worth of imports over the next four years. As important as the aid itself (over 2 per cent of American GNP and initially a sizable percentage of what Europeans could devote to reconstruction) was the incentive it provided for further Western European cooperation – and the clear line it ended up drawing against the communist regimes in the East and the communist parties in the West.[18]

With the fall of 1947, and events of 1948, Europe, at least, became effectively divided. The Russians felt that participation in the Marshall Plan required too much control and withdrew from the conference, forcing their East European governments to follow their lead (Plate 34). They summoned Communist Party leaders to Poland in September and instructed them that there would now be a period, no longer of cooperation, but of long conflict with the West. In February 1948, the local communists forced a coup in Prague, but two months later elections in Italy confirmed the defeat of the communists. Europe was moving toward division. The Western Allies finally did carry through a monetary reform in the zones of Germany under their control and summoned a constitutional convention to create a founding document. The emerging West German State was matched by an East German one in 1949.[19]

The temperature of the conflict grew dangerously high. When the Yugoslav communists rejected Russian leadership, the schism provoked a massive reaction as all the

countries now engaged in political trials against Titoists. Indeed, under the new ideological reaction, political trials became a depressingly familiar feature in all the Eastern European countries, and non-communists, or by 1950–52 loyal communists targeted as Titoists, were forced into abject confessions, imprisoned, and sometimes executed. The wave of persecutions crested in 1952, as Stalin seemed on the verge of a major persecution of alleged Jewish conspirators, including intellectuals and even his physicians, with only the Soviet leader's death in March 1953 interrupting the ominous preparations. The United States meanwhile was caught up in its own rites of political purification, known as 'McCarthyism', as espionage revelations and the climate of the Cold War allowed the demagogic senator from Wisconsin (and other exploiters of anti-communist reaction) to try to impose a climate of political conformity.[20]

Both sides rushed to arm, and the United States helped to organize the NATO alliance in the West and proposed to its allies to accept German rearmament, finally approved by 1955. The Soviets responded with the Warsaw Pact. Fearing the massive land strength of the Soviets, the Allies responded with nuclear deterrence. When the Russians exploded a nuclear device in 1949, Washington pressed ahead with a crash programme to develop hydrogen weapons.

From 1950 to 1953, military confrontation seemed imminent. Indeed Stalin accepted the proposals of Kim Il Sung to try to reunify Korea by force, as it was believed that the United States would not intervene. But in fact the Americans did enter Korea with the agreement of the United Nations' Security Council and fought a devastating war to an inconclusive armistice in 1953. Underestimating how important China considered the stakes, Washington's policy-makers and generals were shocked when the Chinese entered the war in November 1950, but US-led troops managed to stabilize the front by the next spring.[21]

In such a context, it was hardly surprising that American views of decolonization struggles changed. The United States initially encouraged decolonization, urging the British to leave India, then Palestine, pressing the Dutch to give up their rearguard action to hold Indonesia, and ultimately aligning against the British and French during the Suez conflict. Originally the United States wanted the French out of Indochina, but once communist Chinese troops reached the southern border of China, it seemed more important to prop up the French position against the Vietminh than encourage home rule. Still, when Israel, France, and Britain conspired to re-seize the Suez Canal from Nasser, after he nationalized it forcibly, President Eisenhower ostentatiously worked to compel British withdrawal. American objectives were ambiguous. In theory pro-Third World, the US Government was reluctant to accept the fact that national movements were also effective and very loyal communists.

The emerging Third World powers tried to escape falling under the patronage of the United States or the ideology of the Soviets. Their self-proclaimed non-alignment vexed John Foster Dulles, Eisenhower's secretary of state, who tended to see the Cold War as a Manichaean moral confrontation. Still, between 1953 and 1955, there were hopes for a 'thaw' in communist policies after the death of Stalin and the advent of an uneasy 'collective leadership'. The new rulers relaxed the iron grip of the secret police and

executed their colleague, Lavrenti Beria, who controlled this feared agency; they stopped the anti-Semitic purge being prepared, and relaxed the pace of forced industrialization and collectivization in the satellites. By 1956, Khrushchev denounced the crimes and errors of Stalin to the Twentieth Congress of the Soviet Communist Party, a speech that helped to undermine ideas of party infallibility throughout communist ranks. The armistice ending the Korean War was concluded in the summer of 1953, the Indochina conflict was apparently resolved a year later; in 1955, the Russians agreed to an Austrian State Treaty that ended the occupation and provided for a neutral but clearly non-communist regime. After a flurry of notes about German reunification (probably the result of rival policies within the Kremlin), each side fully accredited its respective German ally and stabilized its respective military alliance.

Was there a chance at détente? Eisenhower met Khrushchev and Bulganin, and journalists celebrated 'the spirit of Geneva'. The Soviet leader, who finally consolidated his supremacy by 1956, gave renewed signs of flexibility, but he was not independent enough or at least not inclined to dismantle the Soviet grip on the states already in the Soviet orbit. When in October 1956, reformist Hungarian communists giddily yielded to their citizens' desire to secede from the Warsaw Pact and liberalize the regime, the Soviets invaded to suppress what became a full-scale uprising. The post-Stalin 'thaw' was brought to a halt throughout the socialist world. Instead Khrushchev decided to reinforce the status of Russia's most industrialized but vulnerable protectorate, the East German regime, and opened what became a protracted crisis over the status of East and West Berlin by threatening in 1958 to give the GDR the right to control traffic to Berlin, still officially under four-power control.

The new threat over Berlin reflected what we can now see was a period of confused departures in the history of the Cold War and indeed of world politics – initiatives that were contradictory, might have led to détente, but were still too easily reversed. For the first time since the Second World War, the United States had to face a potential adverse balance of payments situation from the end of the 1950s, which it attributed to the cost of maintaining its troops abroad. Eisenhower's effort to advance personal diplomacy at a new summit conference in 1960 was marred by the Soviet Union's capture and display of a U-2 pilot who was shot down on a covert intelligence-gathering mission high over Russian air space. The American president had to finish his term in 1961 with no real agreements but a vague warning against the role of 'the military-industrial complex' in American politics. His successor, John F. Kennedy, seemed young and innovative but fully committed to continuing an even more effective Cold War struggle, which would soon lead to his supporting the disastrous invasion of American-based Cuban exiles at the Bay of Pigs in Cuba.

On his side, Khrushchev was preoccupied about Mao's ill-conceived 'Great Leap Forward', forced collectivization (and the massive famine that accompanied it), and he recalled Soviet advisors in 1960. The ensuing polemics and rift between the two great Communist powers became a long-term feature of the socialist world. Mao's unleashing of the Great Proletarian Cultural Revolution in 1966, which convulsed China for a decade and seemed to aim at destroying all political and remaining social and cultural

hierarchies, was a frightening spectacle, not only in the West but in the European communist world.

Khrushchev's direction of Soviet and world communist politics was hardly consistent, however (which his colleagues would recognize when they peacefully removed him from power in late 1964). He under-estimated the learning capacity of President Kennedy when they met at Vienna in spring 1961 (Plate 35), although he correctly gambled that NATO would accept the new status quo when he allowed the East Germans, who faced a growing desertion of productive citizens to the West across the still-open inner-Berlin frontier, to erect the Berlin Wall. And after the American debacle at the Bay of Pigs, Khrushchev was emboldened to change the overall strategic balance and place missiles in Cuba, a wager on a windfall gain that led the world to the brink of nuclear confrontation in the fall of 1962.

Both sides were given pause by the brush with catastrophe, and by mid-decade it seemed finally that détente might resume. Foreign policy in the German Federal Republic was moving from the grip of Adenauer's Christian Democratic Union to the now reformist Social Democrats, who under Willy Brandt were preparing the concepts of Ostpolitik or negotiated coexistence with the East German regime. Throughout the Soviet bloc, ideas of mild economic decentralization and market-oriented reforms were gaining favour. Social theorists suggested that both sides might 'converge' toward mixed economies and welfare states. Nonetheless, the growing momentum for reform proved too risky for the cautious Soviet bureaucracy. When, in spring 1968, Czechoslovak party reformers sought democratic reforms and, buoyed by public enthusiasm, ultimately hinted at independence from the Warsaw Pact, Khrushchev's successor, Leonid Brezhnev, decided the movement must be quashed lest it begin spreading (Plate 36). The 'Brezhnev Doctrine' justified Warsaw Pact intervention if socialism was endangered by counter-revolution. As had happened with the suppression of the Hungarian revolt twelve years earlier, the Warsaw Pact intervention and the removal of the Prague reformers disillusioned many communists who had set their hopes on the spreading momentum of liberalization. While in 1956 defections largely involved Western communists, after 1968, the intellectuals and party members throughout Eastern Europe began losing their faith.

## The end of an era

From the late 1960s to the late 1980s, the premises of world politics were transformed in a way that historians have only begun to analyse. At the level of international politics, the changes were logical enough and might well have been predicted. Secretary of State Henry Kissinger and President Nixon spectacularly reversed America's long boycott of China and established relations in 1971. Although the new rapprochement had little immediate effect on Hanoi's policy, the United States extricated itself from Viet Nam, abandoning the South to takeover by the communist North in 1975. Mao himself called a pause to the Cultural Revolution and his successors, above all Deng Xiaoping, moved cautiously but decisively toward economic policies that combined planning and market incentives. Foreign investment and Chinese entrepreneurship unleashed a

process of growth that has transformed the country in the succeeding decades. Party control was challenged by the great manifestations at Tiananmen Square in July 1989, but successfully repressed, and the party managed to keep a growing sphere of political debate and fundamental economic upheaval under its own continuous tutelage.

Britain's return of Hong Kong to Chinese sovereignty was an emblematic step in this remarkable ascent. But it also symbolized how profoundly the relationship between former world masters and subjects had been changed as the twentieth century closed. Formal colonialism ended with the Portuguese military's renunciation of the country's remaining possessions in the mid-1970s. The remaining specimen of the older variant of land-based empire ended with the collapse of the Soviet Union from 1989 to 1991. The communist system had prolonged the possibilities for empire beyond 1917, but for reasons discussed below, could not do so after the 1980s. What critics called neo-colonialism – the domination of Third World economies by the West – did not disappear, but the balance of economic power between the industrialized West and the other world regions changed fundamentally.

'Third World' critics and theorists from Latin America had elaborated a so-called dependency theory (see Chapter 1), which argued that the prosperity of the industrial countries resulted from prolonging the relative backwardness of the non-industrialized countries in order to benefit from cheap labour and under-priced commodities. Such an analysis informed the appeals for redistribution of resources and wealth proposed by the United Nations Conference for Trade and Development (UNCTAD). Opponents of such a prescription criticized instead the developing world's misconceived vast development projects, squandered resources, disincentives for agricultural production, and corruption and repression. It would be an indication of the changed terms of debate that a leading theorist of dependency theory in the 1960s would introduce successful market-oriented reforms as President of Brazil in the 1990s.

After almost thirty years of unprecedented real economic growth, Western countries underwent a difficult decade in the 1970s. The four-fold increase in the price of cheap petroleum decided by the oil-producing countries in early 1974 contributed to both inflation and deflationary pressures. Under the pressures of inflation, the long era of post-war capital-labour solidarity, forged after the Second World War to reconstruct the European economy, began to fray under the pressures of simultaneous inflation and unemployment. The United States, which from 1948 until its involvement in the Vietnam War in the late 1960s had effectively underwritten the international economy by means of the Marshall Plan, military assistance, and private investment, faced mounting resistance to the reserve-currency status of the dollar. In August 1971, President Nixon abandoned the long-term American commitment to maintaining a gold parity for the dollar and forced a re-negotiation of exchange rates, and finally renounced any commitment to purchase foreign currencies for dollars in spring 1973.[22]

Although it could not be recognized at the time, in the 1970s the world economic and territorial system was entering a new phase of development that has only accelerated in the quarter century since. Both capitalist and communist economic systems were put under strain; the growth of a whole new technological sector, information technology and the computer, coupled with the movement of traditional heavy industry to East Asia or Latin America, meant the need to remould the labour movement in the West and East. The First World or the industrialized West saw the slow attrition of its classical industrial labour movement. The Second World or the state socialist economies of the former Soviet bloc simply disintegrated, and what was once known as the Third World tended to bifurcate, with one group of economies successfully industrializing and another falling further behind world standards. Massive waves of new migrants streamed from rural areas to the vast cities of hard-pressed developing nations, and from Asia, the Caribbean, Africa, and the Middle East to Europe and North America. International financial organizations controlling capital and production in vastly separated sites across the world provided a new framework for the economy, far less tied to traditional territorial authorities than previously. National powers in Western Europe tended to devolve 'down' to the regions of the nation-state or 'up' to the European Community (later called the European Union), which significantly enhanced its authority under the striking leadership of Jacques Delors during the 1980s. The United States, which had seemed financially over-committed in Viet Nam and Europe during the Nixon and Carter administrations, enjoyed a remarkable surge of economic growth under President Reagan and his successors, in large measure because it took such a commanding lead in the new computer-based service industries as well as the popular products of a world consumer culture. In addition, the great centre of international state socialism, the Soviet Union, in effect dismantled its own institutions and dissolved the last bastion of old-style imperial control.

How did this remarkable and totally unexpected outcome occur? Once reformist economic and political initiatives seemed to spin out of Communist Party control in the late 1960s, the Soviet leader decided that he could at least assert Russian superpower parity on the basis of the country's huge military capacity, including missiles and nuclear strength. He did secure American willingness to negotiate a series of agreements with NATO members – the Strategic Arms Limitation Treaties (SALT I and II) and the Helsinki and Madrid accords that emerged from the multilateral Conference on Security and Cooperation in Europe (CSCE). The Helsinki Accords provided for the recognition of existing borders (thus protecting East Germany), but also committed the Soviets to agree to guarantees of human rights – a pledge often violated, but one that provided a new generation of critical intellectuals in Eastern Europe with a foothold for organization and protest. Even if suppressed, Charter 77 in Czechoslovakia and, to a far greater extent, the Solidarity movement of 1980 in Poland revealed the growth of dissent within the Soviet bloc. At the same time, Brezhnev's wager on preserving superpower parity on the basis of military power also faltered. The Soviet Union's army became demoralized and mired down in the effort to control Afghanistan. Despite major protests at home, NATO members resolved to match Moscow's deployment of intermediate range missiles that would have possibly subjected Europe to nuclear blackmail. The percentage of Soviet GNP needed to preserve Russia's arsenal was also far higher than the 4 per cent or so required in the West, and the Soviet civilian economy faced grave difficulties during the 1980s. After some brief efforts to grind greater

productivity out of central planning following Brezhnev's death in 1982, and by his two short-term successors, Mikhail Gorbachov (Plate 37) decided he must loosen the grip of state socialism and introduced policies of *perestroika* ('reconstruction', i.e. decentralization and market reforms) and *glasnost* (political openness or transparency). The reforms, necessary though they were, led to consequences that he could hardly predict, including the final dismantling of the communist bloc as it had been established since the end of the First World War. With the dissolution of the Soviet Union, after an abortive coup by foes of reform in 1991, in effect the last of the old land empires had come to an end, and with it, an era of political control that had marked the period from the late nineteenth century.[23]

What forces for international cohesion might now secure world order? For almost a century, from approximately 1870 to the 1960s, the age of imperialism had linked what used to be called the First and Third Worlds. Imperialism and the world economy had confronted tribal structures in western and southern Africa and the Middle East with the centres of finance and industry in Europe and North America. It had prolonged but then destroyed the remaining land-based multinational empires – three of which had disintegrated after the First World War, and the last of which had fallen apart at the end of the 1980s. If indeed there remained new transnational forces that might help the diverse peoples of the world preserve peace and prosperity and a sense of collective dignity, these forces derived less perhaps from their respective political units, than from continuing prosperity and NGOs, who served as trustees for the environment, for human rights, and mitigating disease and hunger.[24] In effect, the NGOs concerned with environment and human rights were the transnational agents that equilibrated the for-profit firms that restlessly drove the international economy forward. Perhaps such political structures as the European Union or NATO would also provide international order.

The United States remained clearly the world's greatest conventional power, but its political agenda was reduced largely to the international enhancement of market democracies, i.e. a type of liberalism that would be favourable to the continued progress of global economic forces. As the twentieth century closed, America was less an empire than a consortium of banks, media giants, a culture industry, innovative computer companies, and enterprising providers of financial services. But it became unclear whether the United States could or would exercise a stabilizing or disruptive role based on its at least temporary military primacy. The devastating assault on the World Trade Center and Pentagon on 11 September 2001 was a shock that left American politics hostage to unforeseeable and contradictory feelings of supremacy and vulnerability. Although most of its allies accepted Washington's military intervention in Afghanistan to hunt down the training grounds of the Al Qaeda 'network' that claimed responsibility for the attack, the subsequent American and British invasion of Iraq in the spring of 2003 drew dissent from some key NATO allies, France and Germany above all. The continued military involvement in turbulent Iraqi politics also divided Americans at home. The United States might conceivably persevere in an effort to take on a wider imperial role, but it was also possible that its volatile public opinion might back away from such an exercise of power, which was unlikely in any case to prevail in a world in which the desire for order

and affluence had to coexist with the claims of militant faith. Was it not possible that by the beginning of the twenty-first century the world community might learn finally to live without empire? This was a revolutionary possibility but also a disorderly one.

4. By the late 1980s, critical Israeli historians abandoned the original Israeli claim that the Palestinians had fled merely under instructions from Arab authorities who wagered on a rapid reconquest. The current debate among historians revolves more around the issue of whether plans for a forced transfer motivated Yishuv (Jewish) authorities from the outset, or expulsions gained momentum village by village during the armed clashes. See E. L. Rogan and A. Schlaim (eds), *The War for Palestine: Rewriting the History of 1948*, Cambridge, 2001; B. Morris, in his contribution, 'Revisiting the Palestinian Exodus of 1948,' documents widespread if 'haphazard thinking about transfer before 1937 and the virtual consensus' thereafter, denies any 'master plan' was applied during the war (pp. 48–49), but also sees more concerted expulsion than when he wrote *The Birth of the Palestinian Refugee Problem, 1947–1949*, Cambridge, 1987. For background see also M. J. Cohen, *Retreat from the Mandate: The Making of British Policy, 1936–1945*, New York, 1978, and Cohen, *Palestine to Israel: From Mandate to Independence*, London, 1988; B. # NATIONAL LIBERATION MOVEMENTS AND THE COLLAPSE OF COLONIALISM

*Nodari A. Simonia*

## THE HISTORY OF THE FORMATION OF NATIONAL LIBERATION MOVEMENTS

The genesis of national liberation movements is connected with the final phase of colonialism when the West entered a higher stage of development and started to export industrial capital to colonies and semi-colonies. It was accompanied by large-scale infrastructure construction, the development of modern communication facilities, the creation of new administrative-bureaucratic structures. Moreover, during this period, a larger part of the local population had access to education. The condition was ripe for the formation of new social classes, including national intellectuals, as well as the press, new political organizations, etc. In other words, there emerged at this time the minimum historical prerequisites for national awakening and gradual transformation of uncoordinated spontaneous manifestations of traditional protest and rebellion into a modern 'nation-wide' anti-colonial liberation movement.

Important international events, such as the revolutions in Russia (1905–7), Iran (1905–11), the Ottoman Empire (1908), China (1911–13) and Mexico (1911–13) gave a powerful stimulus to liberation movements. An even more profound effect on the processes of national awakening was produced by the First World War and the ensuing Russian Revolution of 1917. However, it was the Second World War that became a historical turning point in the fortunes of the peoples of colonies and semi-colonies. The myths that the power of colonialists could not be resisted and 'the white man was invincible' were completely dispelled in the crucible of that war.

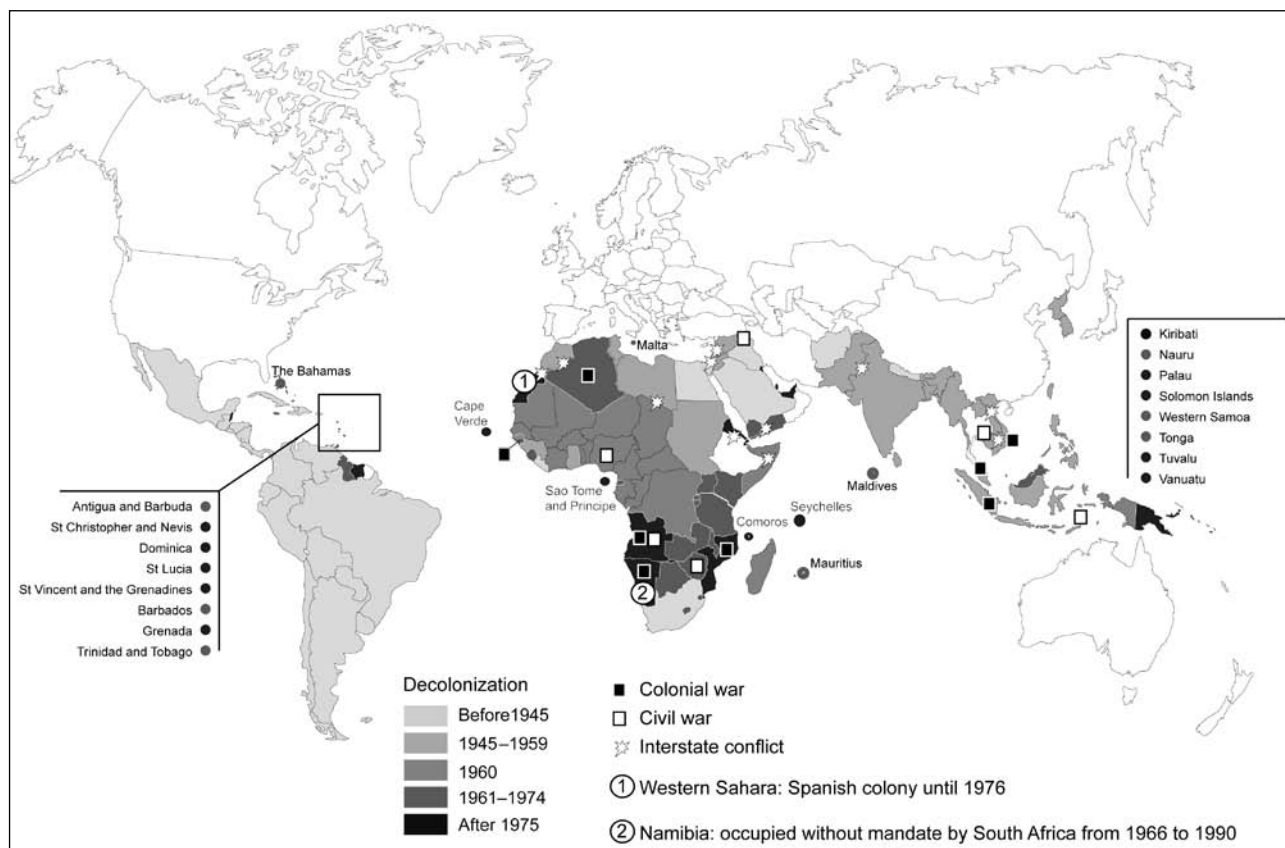
In the aftermath of the war, the countries of South-East and East Asia formed the first echelon of liberated states. Between 1945 and 1949, nearly all the countries of the region proclaimed their independence. They were followed by the states of North Africa (1951–56). As a result, during the first post-war decade, out of 1.5 billion people living in the former colonial countries, about 1.2 billion gained freedom. Ghana (1957) and Guinea (1958) were in the vanguard of a new liberation movement that peaked in 1960 ('the year of Africa'), when 17 African states gained independence. Finally, from the mid-1970s on, the Portuguese Empire began to break down, and later Zimbabwe (1980), Western Sahara (1982) and Namibia (1990) liberated themselves from colonial dependence (Plate 38). With the collapse of the racist regime in the South African Republic in 1994, the political system of colonialism came to an end.

### The specific character of anti-colonial nationalism

Nationalism was the main ideological banner in the liberation struggle of the peoples of three continents. But the case in point is a particular phenomenon, entirely different from what we know about the European experience. The origins of nationalism in Europe in the epoch of absolutism was mainly endogenous, as national identity and national statehood were forming on the basis of the developing domestic market and elements of civil society that began to take shape. The genesis of nationalism in Asia, Africa and Latin America was exogenous. It originated within the framework of the 'metropolitan country-colony' system as a reaction to the unequal situation and unjust distribution of the wealth and power. For this reason, it was, for the most part, based on an anti-foreign attitude from the outset.

Although no two countries in the region are alike, if we compare the conditions under which nationalism originated on different continents, we shall see that a larger proportion of the peoples that managed to retain their traditional statehood during the epoch of colonialism (over fifteen countries) were Asian. Most of them (up to 10) managed to remain semi-colonies. A considerable percentage of the states in Asia are characterized by a high degree of ethnic homogeneity (Japan, both Koreas, Mongolia, Bangladesh), the predominance of a main national group (China, Thailand, Turkey, Iraq, Burma, Kampuchea, Laos, Singapore) or the prevalence of closely related ethnic groups naturally united into one ethnic group (Indonesia, the Philippines). At the same time, such countries as India, Pakistan, Sri Lanka, Iran, Malaysia, Nepal are ethnically diverse. Owing to all these circumstances, the progress of national-state development

*Map 4* **Decolonization since 1945**



Adapted from B. Delaveau, et al., 1989, *Décolonisation et problèmes de l'Afrique indépendante*, Edicef, Paris.

in Asia is quite evident as a peculiar 'country individualism' was taking shape there, and there was no continent-wide pan-Asian movement.

A certain number of factors are responsible for the relative lateness of the awakening of a mass national consciousness in African countries. With the exception of predominantly Arab northern regions of the continent, clan and tribal relations prevailed in Africa, even where state entities were formed. On the whole, Africa was colonized relatively late. As late as 1876, up to 90 per cent of its territory was unclaimed. As a result, anti-colonial ideas originated outside Africa and were based on the awareness of racial rather than national oppression.

**Pan-Africanism**

The idea of African unity was conceived by Edward W. Blyden, from the West Indies, in the middle of the nineteenth century. He advocated unity and race consciousness of an African identity of the Negro or African race. Starting at the end of the nineteenth century, a political movement for the unification of the Negroes against racial oppression took shape. It acquired on official status in 1900 at the first Pan-African Conference, held in London under auspices of the Pan-African Association, led by Trinidadian lawyer Sylvester William. Thus, initially the movement was an initiative of the African diaspora community and was based on the ideas of cultural and

historical uniqueness and claims of the high level of spiritual development among African peoples. Its main objective was to create a single African state. In 1919, Harvard-trained sociologist W. E. B. Dubois organized the first Pan-African Congress in Paris, which was able to voice some of the concerns of Africans and to make suggestions for the educational, social and economic development of Africa and the administration of the mandated territories. The second congress, convened in London, Brussels and Paris in 1921, and the third in London and Lisbon in 1923, drew attention to the ills of the colonial system in Africa and the evils of racial discrimination resulting from the diaspora. But the fifth congress, held in Manchester in 1945, marked a turning point by the active participation of such outstanding figures from Africa as Kwame Nkrumah, Jomo Kenyatta and Peter Abraham, who were determined to shift the movement to Africa and actively pursue independence and the unity of the African continent. Beginning in the late 1950s, pan-Africanism began gradually evolving from a movement for continental unification into a movement for the united action of independent African states. The concept of African unity was interpreted in different ways by different African leaders. The various tendencies were represented at several conferences held in Africa in 1958, 1960, 1961, which resulted in the creation of the OAU (Organization of African Unity) in 1963. Ever since, all efforts (particularly in the 1980s and first half of the 1990s) to revive the ideals of pan-Africanism have been doomed to failure.

## Arab nationalism

The geographical location of the Arab world – at the junction of two continents – could not but affect the processes of national awakening. In addition, the Arabs had been conquered and remained part of the Ottoman Empire until the end of First World War. On the one hand, this factor served to consolidate the spirit of Arab unity, but on the other hand, the Arabs within the Ottoman Empire were isolated from direct Western influence for many centuries. Common historical destinies encouraged the emergence of a pan-Arab movement. In contrast to pan-Africanism, pan-Arabism was based on shared ethno-cultural, linguistic and religious factors which proponents of pan-Arabism use in their broad interpretation of the concept of a single Arab nation.

In the 1920s and the 1930s, the conditions were ripe for the emergence of 'regional' (i. e., country) nationalism, particularly in Egypt, Sudan, Syria, Lebanon, Tunisia and Algeria. Thus, pan-Arabism began to coexist alongside with 'regional' nationalisms.

Algerian nationalism was profoundly affected by the long and unrelenting liberation struggle against the French colonial power (1954–62). This struggle provoked internal radicalization and gave rise to pan-African and even 'Third World' (F. Fanon, 1925–61, French politician and psychiatrist) guidelines and orientations. In the course of struggle for liberation, Algerian intellectuals adopted a critical attitude towards a colonial-capitalist political economy and drew up guidelines for the restoration of the economy through centralized planning. Their position was formulated in 1962 by the Tripoli Programme of the National Liberation Front (NLF). After independence, nationalization was carried out and the state sector was established. The state established control over foreign capital activities. A large-scale exodus of the European population set the stage for the emergence of the system of

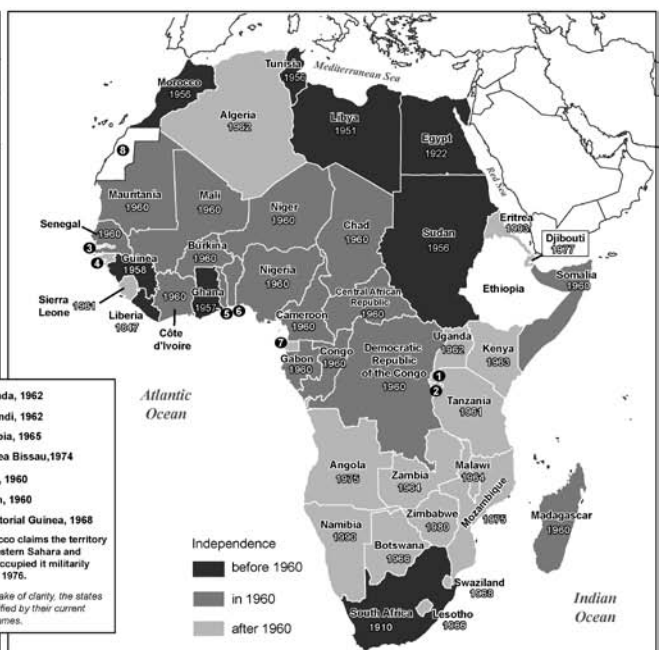
the people's self-government, and the first Congress of the NLF, held in 1964, approved the course for 'socialist reforms' (land reform, nationalization of foreign trade, banks, etc.). Subsequently, the government of Houari Boumediene began placing great emphasis on nationalism. In the 'National Charter' (1976), the principle of 'self-reliance' was stressed and Islam was proclaimed the state religion. In the revised version of the charter (1986), a more important role was given to private national capital.

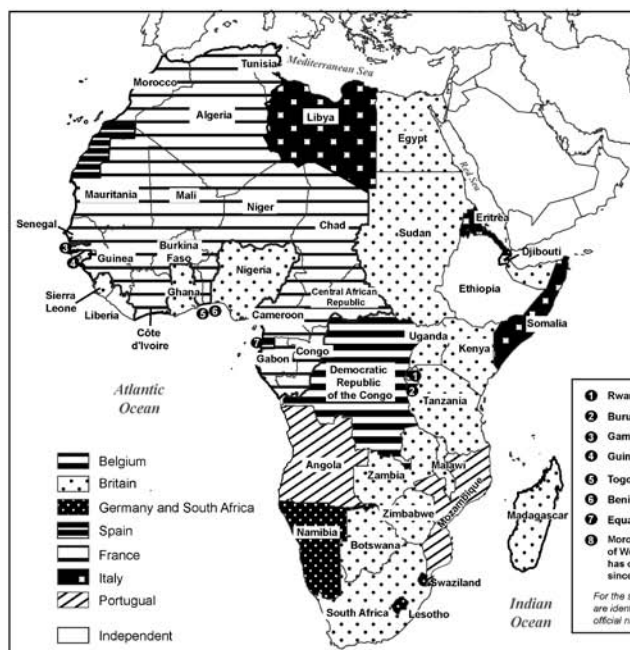
## Nationalism in Latin America

Processes of national awakening in Latin America had a unique character. By the beginning of the nineteenth century, colonialism in Latin America had not paved the way for any of the usual prerequisites for the emergence of nationalism. The independence gained between 1810 and 1926 by most of the Latin American countries resulted primarily from European events – Napoleon's occupation of Spain and Portugal and the overthrow of the long-standing monarchies. Consequently, independence did not reflect the emergence of national states, and the process of the formation of nations was a lengthy one.

At the beginning of the twentieth century, cultural nationalism prevailed; however, before long, a more efficient form emerged. The so-called 'economic nationalism' proclaimed the priority of the nation's ownership of all land, water and natural resources (Mexican Constitution of 1917). In practice, it resulted in the establishment of large state corporations and the nationalization of basic industries, the policy of industrialization, and the introduction of restrictions on the activities of foreign capital (Argentina, Mexico, Chile and Brazil). This type of nationalism represented a compromise between the semi-colonial cosmopolitism of the old ruling circles and radical nationalists, who disclaimed the role of external factors. It was oriented toward domestic

*Map 5* **Colonization in Africa**

**Independence in Africa**




production and consumption, but for the sake of successful economic development, the rational use of foreign investments and assistance was also advocated.

The Pan-Continentalism movement originated in the course of the liberation struggle and was initially directed against Spain and Portugal. Led by Simon Bolivar, it assumed the spirit of continental unity – *americanismo*. Later on, the idea of continentalism acquired a new base – *anti-yankeeism* (directed against the United States) – particularly after the Mexican War and as a consequence of a broad interpretation of the Monroe Doctrine. In the 1930s and 1940s, the United States made an attempt to assuage those negative attitudes and to weaken Latin American continentalism through the concept and the policy of 'multilateralism'.

## DIFFERENT MODELS OF SOCIALISM

The upsurge of liberation movements and the collapse of the colonial system were played out within the framework of the confrontation between two systems. As a consequence, in a number of the countries, communist parties managed to take over the leadership of liberation movements, thereby facilitating their rise to power.

### China

After the People's Republic of China was founded there was some disagreement among the leaders of the country's Communist Party: some advocating following Stalin's model while others remained faithful to Lenin's 'New Economic Policy'. The unique feature of the socio-economic policy of the new Chinese leadership was the way it dealt with its bourgeoisie (creation of mixed state-private enterprises, policy of redemption of the private capital, etc.). Subsequently, the development of Chinese society began to follow the tenets of Maoism. In 1958 and 1959, Mao Zedong undertook the 'Great Leap Forward' that resulted in the establishment of rural communes and in large-scale industrialization (Plate 39). The country strove to achieve self-reliance and the level of highly developed capitalist countries. From 1966 to 1976, the 'Great Proletarian Cultural Revolution' against 'old ideas, old culture, old habits and old customs' was launched. However, after Mao's death (1976) and Deng Xiaoping's return to power, radical economic reforms were undertaken, though the Communist Party retained its leading political role. China is now in the process of establishing a socialist market economy.

### Viet Nam

Vietnamese socialism emerged from the flames of the armed liberation struggle that lasted for 35 years (initially against Japanese occupation, then against French colonialism and lastly against the military intervention of the United States). From the very beginning of the struggle the Communist Party managed to organize a broad national front – Viet Nam Independence League (or Viet Minh). As the nucleus of that front, the Communist Party did not bring forward any socialist slogans and pursued a rather flexible social policy that brought it mass support, particularly from the peasants.

Before reunification with South Viet Nam, the country's social development could be described as the synthesis of the Soviet political system and a 'war communism' type of economy. In 1979, the leaders of the country made the first fundamental revision to their development strategy. More emphasis was placed on material incentives, private enterprise, expansion of the market for consumer goods, etc. In 1986, a new programme of liberalization of the economy was adopted. The main objective of the programme was industrialization and modernization, the granting of privileges to private capital and drastic reductions in the state sector. As a result of a new law on foreign investments adopted in 1987, the economy became more open.

### Cuba

Perhaps the main peculiarity of the socialist regime in Cuba is the fact that the policy of the United States had a dominant role in its genesis and development. Fidel Castro, who since 1956 had led the partisan war against the dictatorial regime of Batista and came to power on 1 January 1959, was a radical nationalist who did not share communist convictions. From the very beginning, the United States took an extremely negative attitude towards the Castro regime. In January 1961, it broke off diplomatic relations with Cuba and imposed a diplomatic and economic blockade on the island. In April, they organized the Bay of Pigs landing operation. All these actions pushed Castro to the left and made him seek allies in the socialist camp. Castroism differed from both the Soviet model, distinguished by the important role of the Communist Party and a preliminary organization of the proletariat for the seizure of political power, and from the Chinese model, according to which the Communist Party joined the United Front, which encompassed the proletariat and the peasantry as well as the bourgeoisie. Castro and his followers in Latin America (Fidelistas) believed that in order to overthrow a corrupt dictator, it sufficed to organize a guerrilla war in rural and urban areas.

Among the early features of Cuba's distinctive brand of socialism was total disregard for the principle of material incentives and an emphasis on moral incentives. However, Cuban leaders eventually had to abandon such policies and, from the late 1960s, the features of the Soviet model became more and more prominent in the country's social development. After the end of the Cold War, Cuba found itself in a crisis situation that impelled the leaders of the country to start developing a mixed economy.

### Nationalist socialism

From the very start of their activities, a large number of the national leaders of liberation movements came under the influence of socialist ideas. However, practically all of them combined the general idea of socialism with their specific types of nationalism and traditionalism.

### Indonesian socialism

The ideology and practice of Indonesian socialism is connected with the name of the country's first president,

Achmed Sukarno (Plate 40). It is based on five principles known as 'Pancasila': nationalism, internationalism, democracy, social justice, belief in God. Alleging that Western liberal democracy was inapplicable to Indonesia, in 1957 Sukarno proposed the system of 'Guided Democracy' on the basis of which he formed a Mutual Cooperation Cabinet (Goton Royon Cabinet). Soon afterwards, the concept of 'Indonesian socialism' was supplemented by the ideas of NASAKOM (an acronym for: nationalism, religion and communism). The external aspect of 'Indonesian socialism' was radical anti-colonialism, anti-neocolonialism and anti-imperialism.

## Arab socialism, the Baath movement

Originating in Syria in 1953, this movement appealed to the poor, landless peasants for support against foreign influence and big landowners. It encouraged the nationalization of industry but also favoured private property and enterprises in the hopes of improving general social welfare. The Baath motto was 'Unity – Freedom – Socialism', 'Unity' referring to a single centralized Arab State and 'Socialism' being the economic essence of Arab socialism, which was essentially nationalist and bound to serve the Arab nationalist cause.

## Bandung and the 'Third World' concept

Almost immediately after the emergence of new independent states, they became an object of confrontation between the 'two world systems'. At first, the prevailing opinion in the West (particularly in the United States) was that the former colonial and dependent countries should embark upon the path of modernization and Westernization (Edward Shils, Lucian W. Pye, David E. Apter, S. P. Huntington, S. N. Eisenstadt and others). The Soviet bloc believed that liberation revolutions would not end at the nationalist stage and would develop into social revolutions. The African and Asian countries considered that they were trying to become an independent part of the world community. The Afro-Asian conference in Bandung (Indonesia) was a landmark in the history of newly independent states. Among the participants of the conference – convened in April 1955 on the initiative of Indonesia, India, Pakistan, Sri Lanka and Burma – were such prominent political figures as Sukarno, Nehru, Zhou Enlai, Pham Van Dong and Norodom Sihanouk. Representatives of 29 Asian and African countries approved 10 principles of international cooperation.

Initially, the term 'Third World' (*le tiers monde*), referring to a particular world community, was widely used in France (A. Sauvy, G. Balandier), and subsequently around the world, to distinguish developing countries from the 'First' (developed countries) and 'Second' (socialist countries) 'Worlds'. Later on, as a synonym of the 'Third World', the term 'the South' (as opposed to 'the North') was introduced. During the 1960s and 1970s, attempts were made to use the criteria of under-development and poverty for classifying the countries of the Third World. However, with the process of differentiation between developing countries accelerating, all these attempts were doomed to failure. Within the United Nations and its agencies the term 'Fourth World' was coined.

## Non-Aligned Movement (NAM)

The idea of non-alignment has roots in the socio-political and religious-philosophical teaching of Mahatma Gandhi. A distinctive feature of Gandhi's philosophy is the necessity of mass non-violent resistance to colonialism ('Satyagraha' or truth grasping) and using the strength of one's mind against brute material force. Jawaharlal Nehru (Plate 41) transferred the basic principles of Ghandi's teachings to the sphere of foreign policy. In July 1956, on the island of Brioni (Yugoslavia) I. Tito, J. Nehru and G. A. Nasser signed the declaration that proclaimed the principles of the Non-Aligned Movement. In 1961, 25 state and government leaders of the non-aligned countries gathered in Belgrade for their first conference, which formulated the movement's three main goals: scaling down global confrontation, the struggle against colonialism, and economic development.

The movement emerged as a reaction to the Cold War and the rigid bipolarity of the world in the 1950s. At that time, even large developing countries were not able to effectively counteract pressure from the superpowers and resist being drawn into military-political blocs (the Baghdad Pact, CENTO, SEATO, etc.). For this reason, certain countries decided to resort to collective diplomacy under the banner of the Non-Aligned Movement (Plate 42). The Second NAM conference, which took place in Cairo in 1964, put forward the idea of forming the Group of 77, which was established at the UNCTAD conference the same year. The fourth conference, held in Algeria (1973), adopted the Declaration and the Programme of the New International Economic Order (NIEO). The following year, a special session of the United Nations General Assembly approved the Declaration establishing the NIEO.

By the early 1990s, 10 conferences of the NAM had taken place, and its membership rose to 111 countries in 1995. However, after the Cold War ended, the NAM found itself in an entirely new environment: political decolonization had been completed, developing countries had become increasingly differentiated, and the internal fragmentation within the movement was intensifying. Regionalization and the formation of a multi-centred world structure had begun. The NAM was confronted with the need to reconsider its objectives, strategies and, probably, even its very existence.

## The Suez Canal and the Persian Gulf

During the entire twentieth century, the Middle East had been in the spotlight of world public opinion and the centre of conflicts between various geopolitical, military and economic interests. Already considered strategic in 1869 at the opening of the Suez Canal, the region acquired even greater importance in the twentieth century when new oil deposits were discovered there.

The Suez Canal is one of only four international passages linking two seas. After the Egyptian revolution of 1952, the British troops remained in the canal zone until July 1956. By that time, Egypt's relations with the West had grown rather tense. Among the factors that contributed to the West's negative attitude towards Egypt was the independent course pursued by Nasser, his role as the undisputed leader of the liberation movement in the Arab world, and Egypt's cooperation with socialist countries. In 1956, the United States and England refused to finance the construction of

*Map 6* **United Nations Partition Plan (1947)**

*Map 8* **Israel and the Occupied Territories (1999)**

Adapted from E. Barnavi, 1982, *Israël au XXᵉ siècle*, PUF, Paris, pp. 318–19.

the Aswan High Dam, despite their earlier promises. In response, Nasser nationalized the canal, intending to use the revenue to finance the construction of the dam. England, France and Israel retaliated by occupying the canal zone. In a statement issued 5 November 1956, the Government of the Union of Soviet Socialist Republics demanded that military operations be stopped and foreign troops withdrawn. The United States also decided not to support their allies. As a result, foreign troops left Egypt in March 1957.

Today, the Persian Gulf is considered the world's most critical sea route: two-thirds of the world's oil exports travel through the Gulf en route to consumers. For the past two decades, at least two major conflicts of global importance have broken out in the Gulf region.

The Iran-Iraq War lasted eight years (September 1980–August 1988), and many problems resulting from it remained unresolved in the early twenty-first century. The rivalry between Iran and Iraq in the Gulf has a very long history. The dispute over Iran's right to use Shatt al-Arab waterway had been settled in 1975 in favour of Iran. After Iran's Islamic Revolution, Iraq decided to break the accords of 1975 by attempting to win back oil-rich Khuzistan, conquered by Iran in 1925. In September 1980, Iraqi troops invaded Iranian territory, making it clear that the war would be protracted. A cease-fire signed by both sides in August 1988 put an end to the fighting.

The second war in the Gulf began in August 1990, soon after the previous conflict, when Saddam Hussein invaded Kuwait and proclaimed it Iraq's nineteenth province. The Soviet Union joined the international community in strongly condemning this act of aggression. The United States initiated the creation of a multinational Allied coalition, which consisted primarily of Americans (532,000 soldiers).

The United Nations Security Council condemned the invasion and adopted a resolution to impose economic sanctions on Iraq. It demanded unconditional withdrawal of Iraqi troops from Kuwait and acknowledged the latter's sovereignty. Moscow's attempts to find a compromise political solution ended in failure. Operation Desert Storm, launched on 24 February 1991, succeeded in defeating the Iraqi troops.

**Palestine and the creation of Israel**

The Palestine issue is perhaps the oldest problem in the Middle East. In the Balfour Declaration, issued in November 1917, Great Britain committed to support the establishment of a Jewish national homeland in Palestine. Subsequently, Jewish immigration rapidly increased, especially between 1932 and 1938 owing to the persecution of Jews by Nazi Germany. Indeed, the Holocaust contributed tremendously to Jewish immigration to Palestine: by 1945, some 564,000 Jews were living in Palestine. In 1947, the United Nations General Assembly adopted the Partition Resolution, which provided for the division of Palestine into two states: one Arab and the other Jewish (the resolution was supported by the United States and the Soviet Union) (Map 6). The Arab state was never established, while the creation of the State of Israel was proclaimed in May 1948 and was immediately followed by the first Arab-Israeli War (1948–1949) (Map 7). As a result of that conflict, Israel not only retained all of its territory but also seized part of the territory that had been apportioned to the Arab state. The remaining part of the territory was annexed by Jordan (the West Bank and East Jerusalem) and Egypt (the Gaza Strip). In 1964, the Palestine Liberation Organization (PLO) was established. In October 1974, the United Nations General Assembly voted to officially recognize the PLO as the sole representative of the Palestinian people by an overwhelming majority (105 against 4).

Soon after the Camp David Accords (1978) and the Egyptian-Israeli Peace Treaty (1979) were signed, the Israeli

Parliament (Knesset) officially legitimized the annexation of East Jerusalem, and in the summer of 1982, Israel invaded Lebanon to drive out PLO leaders and its armed forces. Only in September 1993 did both sides finally sign the Oslo Accords, which called for the transfer of power over the West Bank and the Gaza Strip to the Palestinians. For various reasons however, the Oslo Accords failed, and by the century's end, no solution appeared in sight (Map 8).

## POST-COLONIAL PROBLEMS
## FORMER COLONIAL POWERS
## AND NEW STATES

*Nodari A. Simonia*

### RACISM, COLONIALISM AND THEIR CONSEQUENCES

Colonialism destroyed the integrity of traditional life and the natural interplay between people and nature, and slavery was revived in order to provide plantations and mines with inexpensive manpower. Up to 10 million black people from Africa were resettled in the West Indies, the Americas, thereby generating a number of serious problems, some of which have yet to be solved. Africa itself was divided into three zones (Samir Amin): (a) Africa of the labour reserves; (b) Africa of the colonial trade economy; and (c) Africa of the concession-owning companies.

In fact, European expansion resulted in the formation of three types of colonies: (1) colonies governed by European countries, (2) 'colonies' inside the mother countries (the United States and a few Latin American countries), and (3) colonies with fragments of mother countries within (South Africa, South Rhodesia).

In all cases, colonialism gave rise to racism, racial discrimination and segregation. The first type of colonies solved this problem upon gaining independence. The United States, which started the process of combating racism during the Civil War (1861–65), became the scene of race riots and disorders in the decades following the Second World War. (The murder of the Nobel Peace Prize winner Martin Luther King [Plate 43] in 1968 provoked racial unrest in some 125 towns across 29 US states.)

However, the struggle against racism was the most fierce and bloody in the Republic of South Africa. Legalization of racism, which formed the basis of the state system of apartheid, actually began with the establishment of the Union of South Africa (1910) and continued after it joined the British Commonwealth (1931). When the coalition of Afrikaner nationalists came to power in 1948 and the National Party was formed in 1951, the regime, based on the Afrikaner peoples' belief in their 'god-given mission', was finally and totally legitimized (Plate 44). After the adoption of the Bill on Bantustans (1959), 73 per cent of the black population became citizens of 10 Bantustans (reservations), to which 13 per cent of the most barren land was allotted. Since that time, the African peoples' struggle for liberation acquired greater radicalism, with landmarks events such as the Sharperville massacre (1960) and the Soweto uprising (1976). Beginning in the mid 1980s, the country was in a state of a civil war. In the end, the ruling regime had to begin negotiations with the main opposition force – the African National Congress and its leader Nelson Rolihlahla Mandela who had served over 27 years in jail. After the first free and general elections in May 1994, the regime of apartheid collapsed.

### Fragmentation

One of the extremely negative consequences of colonialism was political, social, ethnic, religious, economic and cultural fragmentation of developing societies. Among the principal factors of fragmentation were artificial borders drawn by the colonialists. Even when they were withdrawing from colonies, Western powers tried to change the borders to their own advantage as exemplified by the division of the Indian subcontinent on the basis of the region's prevailing religious differences, the United States of Indonesia imposed by Holland (1949–51), the Malayan Federation, and attempts to form various federations in Africa. African territories were divided without regard for the ethnic groups and the emerging state entities. As a result, the new political entities brought together fragments of different ethnic groups (Bacongo, Ewe, Masai, Yoruba in Central, West and East Africa and many others), thus setting the stage for both conflicts between neighbouring states (between Chad and Libya, Zaire and Angola, Burkina Faso and Mali, Somalia and Kenya, Somalia and Ethiopia, etc.) as well as internal clashes that sometimes developed into civil wars (Nigeria, Ivory Coast, Sudan, Zaire, Ethiopia). In a number of cases, they even escalated into veritable genocide, as occurred between the ethnic groups of Tutsi and Hutu in Rwanda (1959 and 1994) and Burundi (1972 and 1993–94).

Ethnic diversity leads to political fragmentation: the struggle between different ethnic groups for power, status, possession of economic resources, etc. The existence of multiple loyalties (family, clan, tribal, state) complicates political processes, impedes the process of governing and destabilizes society. The above-mentioned factors also

account for social fragmentation and for the fact that the formation of classes and civil society will be a long process. Ethnic fragmentation is often combined with religious fragmentation, which creates additional difficulties. These contradictions are also aggravated by the fact that during the colonial period, many peoples and ethnic groups in Africa lived in the sphere of influence of different European cultures (English, French or Spanish is spoken in most former colonies). In addition, the formation of modern society in the former colonial countries also encounters economic fragmentation, the absence or weakness of the domestic market, enclave economic development, causing social tension and at times regional separatism.

## THE PROBLEM OF MINORITIES

Ethnic fragmentation poses a particularly serious problem whenever minorities reach a comparatively high level of self-identification and political consciousness. As a rule, their assimilation by the dominant nation becomes rather difficult, and in some cases impossible. Almost from the outset of independence, such minorities wage an unrelenting struggle for self-determination. As a rule, their struggle begins with demands for cultural and administrative autonomy, but having met with opposition from the central power, they radicalize their struggle and begin to demand secession (separatism).

The problem of minorities sometimes involves exclusively internal affairs of the concerned state. In other cases, the minority is scattered across two or even several neighbouring states, adding a regional dimension to the problem. An example of the former case is the Sudan, where Nilot tribes in the southern part of the country waged an armed struggle from 1955 to 1972 and finally achieved autonomy and self-government (Plate 45). Another example is the Igbo's attempt to secede from Nigeria (1967–70) to create an independent Biafra. The resistance was repressed, but in order to prevent new attempts of separatism, federalism was instituted in Nigeria. The only example of separatism brought to completion in Africa is Eritrea, which seceded from Ethiopia in 1991, as a result of an armed struggle waged since the early 1960s.

More complex is the problem of fragmented minorities. The governments of the region usually manipulate such minorities. A classical example is the destiny of the Kurds, who live primarily in Iraq, Turkey, Iran, Syria and Azerbaijan. After the First World War, the Western powers decided to establish a Kurdish state (Sevres Treaty, 1920), but this promise was never fulfilled. The destiny of the Bengalese people is also noteworthy. After the division of colonial India, the majority of the Muslim population found itself in Pakistan, while the Hindus were predominantly settled in India. Since the first days of independence, the Bengalese in Pakistan had been slighted and exploited by the Urdu-speaking population of the western part of the country. This eventually led to a civil war and the establishment of the Republic of Bangladesh.

### Dependence

Political liberation by no means eliminated economic, technological and military-political dependence of the developing countries. Generally speaking, colonialism destroyed the integrity of their economies. Certain local structures maintained the colonial division of labour in collaboration with the mother country, while others perpetuated a stagnating farming tradition. Plantation farming, peasant commercial production and mining enterprises continue to be export-oriented up to the present day. The entire infrastructure was created in such a way that the colony's economy was more closely connected with the mother country than with the other regions of the colony.

One of the most vivid manifestations of economic dependence is the monocultural character of production. In the 1960s, about 70 independent states relied on the export of one to three primary commodities or minerals (oil, copper, bauxite, etc.), agricultural commodities (cotton, jute, rubber, copra, etc.) or foodstuffs (coffee beans, peanuts, cocoa beans, tea, bananas, rice, citrus fruits). This policy laid the foundation for the subsequent marginalization of certain countries and was responsible for the crises from the 1970s to the 1990s, which were aggravated by a slump in raw materials prices and a rise in the prices of industrial imports. The technological revolution passed those countries by, and Western countries made investments mainly in their own economies or in a small number of developing countries. As a result, from 1980 to 1991, the 42 least-developed countries registered a negative average annual growth of the GNP per capita (-5.4 per cent), while 10 low-income and 20 medium-income countries also had negative or zero growth. The efforts of the International Monetary Fund (IMF) and the World Bank to apply 'structural adjustment' measures to such countries were unsuccessful because these organizations did not envisage the overall restructuring of production, the elimination of their economies' dualism and their conversion into national economies based on the domestic market.

However, even those countries that had taken the path of industrialization for many decades remained technologically dependent (on the importing of equipment, technical assistance, capital investment, patent and license purchases). Moreover, the number of scientists and engineers in the Third World engaged in research and development ranged from 4 to 16 per 100,000 people from 1970 to 1976 (compared to 124 to 240 in developed countries). In the mid-1970s, developing countries accounted for only 2 to 3 per cent of the world expenditures for research and development.

Developing countries are also dependent on wealthier nations in the military-political sphere. Here we can observe the logic of the 'vicious circle': a difficult economic situation, political instability, local and regional conflicts lead to a substantial increase in military spending and the import of armaments, which, in turn, drastically reduces the potential for investment in production and further deteriorates the economic situation. The value of armaments imported from developed countries to the Third World totalled US$4.2 billion in 1960 and rose to US$16.5 billion in 1991.

### Poverty

Although destitution and poverty occurs in highly developed Western countries, the nature of these phenomena is fundamentally different in developing countries. As a result of the socio-economic dualism imposed by colonialism, up to 70 to 75 per cent of the population has remained in the

traditional agricultural sector, which has been traditionally exploited (taxes, supplies of low-price foodstuffs, forced labour at the construction of public project, etc.). During the first decades of independence, this state of affairs changed very little, partly owing to the Western concept of promoting industrialization at the expense of the agricultural sector. Therefore, it is hardly surprising that many rural areas fell into a state of degradation and per capita output of foodstuffs drastically decreased. From 1952 to 1962, the average annual growth of foodstuffs output amounted to 0.7 per cent; by contrast, from 1962 to 1972, it decreased to a mere 0.2 per cent. According to the World Bank, in the mid 1970s, about 85 per cent of the poor were concentrated in rural areas.

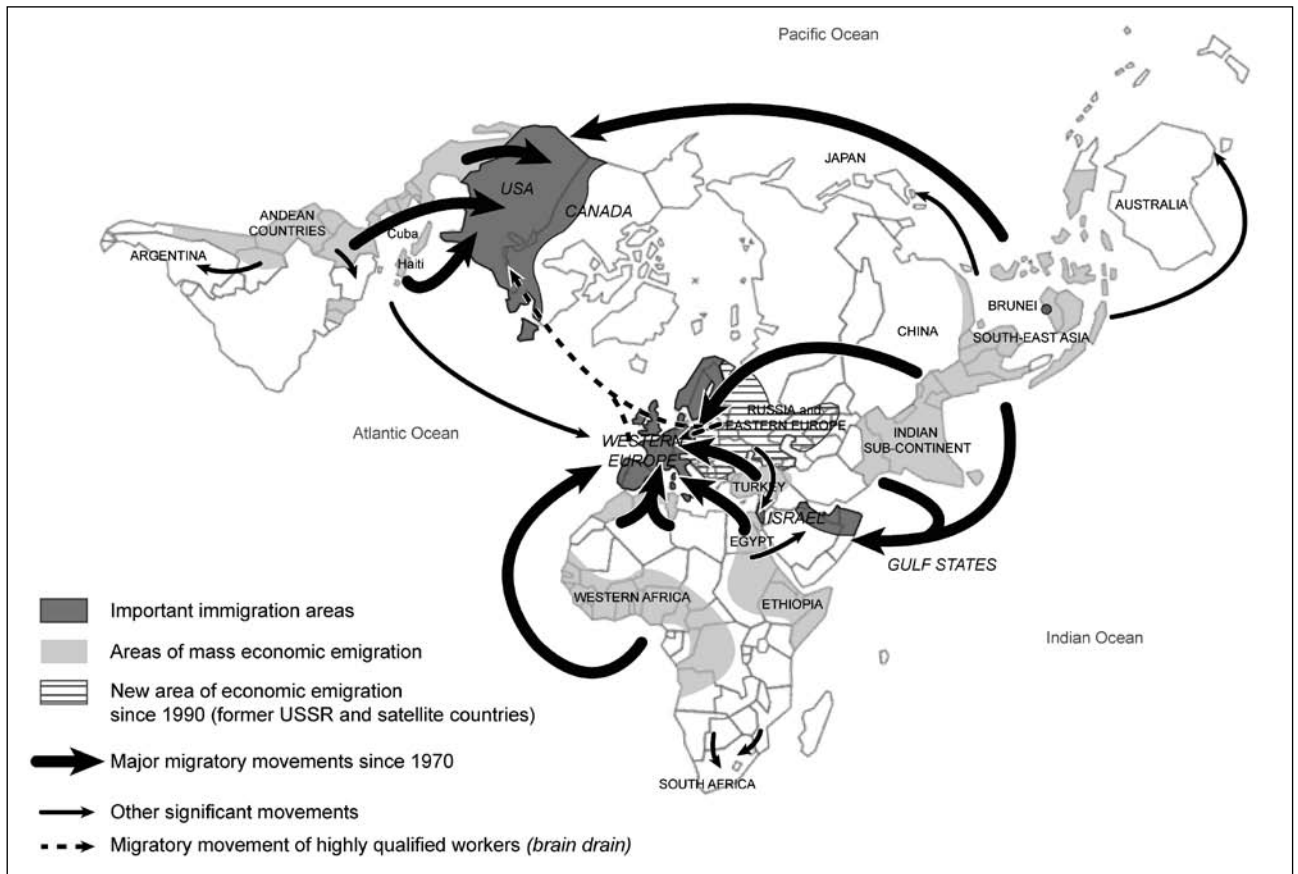
Pauperization of the rural population has contributed to large-scale migration to urban areas, a process that can be defined as 'galloping urbanization'. Numerous slums are emerging in cities and their surrounding suburbs. According to the United Nations, the urban population of Africa in 1950 totalled 33 million people (14.5 per cent of the total population); by 1985, it had risen to 174 million people (31.1 per cent). In Latin America, the urban population numbered 69 million people (41.5 per cent) in 1950 and 279 million people (62.2 per cent) in 1985; in Asia, 226 million (16.4 per cent) and 797 million (28.1 per cent) during the same years. In the mid-1980s, over a dozen megalopolises emerged: ten of them with a population of more than 3 million people while the four largest comprised over 10 million. Thus, in the 'Third World' poverty has become an urban problem as well (Plate 46).

Available data indicate that, at least in absolute terms, poverty in the 'Third World' is not decreasing but growing (in a few countries, poverty has also increased in relative terms). In 1971, when the United Nations published the list of the least-developed countries, it included 25 countries; 10 years later there were already 31 such countries, and in 1990, the 'Fourth World' comprised 42 states with a combined population of 400 million people. The number of poor people in the other countries of the 'Third World' was comparable. Half of all poor people live in South Asia: 560 million people or 49 per cent of the total population in 1990. In Central America, about 60 per cent of the population live in poverty. The situation is particularly critical in sub-Saharan Africa, the only region in the world where the growth of agricultural production lags behind the population growth and where the Overseas Development Administration (ODA) meets not only its basic foreign exchange needs but also most domestic investment requirements and, increasingly, recurrent costs. On the whole, according to the World Bank's estimates, the number of people that are not able to satisfy their essential needs (food, drinking water, sanitation, health care and education) exceeded 1.1 billion in the early 1990s.

### Displacement of Peoples

All the factors listed above gave rise to the phenomenon of large-scale migration in the twentieth century. Two types of

*Map 9*  **Principal migratory movements at the end of the Twentieth Century**



Adapted from G. Chaliand et al., 1998, *Atlas du millénaire: La mort des empires 1900–2015*, Hachette, Paris.

causes can be singled out: military-political violence and socio-economic needs. Violence gave rise to a problem of refugees and internally displaced people. During the past decade, the number of such people has grown drastically, and the problem has acquired a global character. According to the data furnished by the Office of the United Nations High Commissioner for Refugees, in the mid-1980s, the total number of refugees worldwide was 10 million. In 1991, World Refugee Survey estimated that there were at least 20 million internally displaced and 16 million refugees. This process began with decolonization. Mass flows of forced migrants could be observed during the division of colonial India (Plate 47) or the period of the British mandate over Palestine. The war in Indochina brought about a new wave of refugees (about 1.3 million people emigrated from Viet Nam alone). Up to 6 million Afghan people left their country, and another 2 million were forced to move to other regions because of the Soviet Union's armed intervention in Afghanistan. In the 1990s, Africa accounted for about a quarter of the total number of migrants: about 1 million people fled from Ethiopia and another million were internally displaced; in Mozambique, 1.4 million emigrated and 2 million were internally displaced. In 1994, 2 million refugees fled from Rwanda. In Sierra Leone, there were 400,000 internally displaced, and an additional 380,000 were forced to seek shelter in Guinea and Liberia. In their turn, 400,000 Liberians settled in Sierra Leone, 600,000 in Guinea and 250,000 in the Côte d'Ivoire.

# RESPONSES TO POST-COLONIAL PROBLEMS

*Nodari A. Simonia and Sophie Le Callennec*

## GARVEYISM, 'NEGRITUDE' AND BLACK POWER

Awakening of racial self-consciousness of black people was a natural response to centuries of colonial oppression and white peoples' belief in the universality and superiority of their culture. One of the earliest manifestations of such a response in the twentieth century was Garveyism. Marcus Garvey, a native of Jamaica, where he is considered a national hero, founded the Universal Negro Improvement Association (1914). In 1917, Garvey moved to Harlem in New York City, where he became a political activitist and launched the 'Back to Africa' movement. Garveyism represented radical anti-colonialism and anti-racism. It maintained the dignity of the Negro race, without idealizing its history and culture. Garvey advocated racial purity and considered mulattoes as 'traitors of the Negro race'. His vision was to encourage black people to 'buy black' by supporting the business of black entrepreneurs. Eventually, he founded the Black Star Shipping Line to foster trade and black emigration from North America to Liberia and Ethiopia in the hope of creating an independent African state as a base for the continent's liberation.

Whereas Garveyism was widespread in English-speaking Africa (Liberia, Nigeria, Sierra Leone), the concept of *négritude* (blackness) was popular mainly in the former French possessions. The concept was advocated by Aimé Césaire, from Martinique, but the figure who greatly contributed to the theoretical content of negritude was Leopold S. Senghor, who eventually became president of Senegal and a prominent International Socialist. Initially negritude was an intellectual reaction to France's assimilation policy. Senghor defined the concept as follows: '*Négritude* is the whole complex of civilized values – cultural, economic, social and political – that characterize the black people'.[1] According to negritude, black Africans, by virtue of their racial origin and the particularities of their culture, perceive the world in their own unique way and subconsciously communicate to each other the psychological experience of the black people. According to Senghor's concept, the innate intuition and sensuality of the Africans contrasts with the cold rationalism of Westerners. After the Second World War, the concept became popular among the writers of Africa, Europe and the Caribbean.

Negritude had a marked effect on numerous movements advocating black nationalism and black consciousness that were widespread in the 1960s and 1970s. In Haiti, black intellectuals waged a successful campaign for the recognition of Creole, the language of the masses, as an official national language (1969), on equal footing with French, the language of the elite. In the United States, a number of moderate and radical movements coined the 'Black Power' slogan. It was also used by the Nation of Islam (also known as the Black Muslim movement), founded in the 1930s and led by Elijah Muhammad from 1934 to his death in 1975, at which time the supporters of the movement numbered some 150,000 to 200,000. Another proponent of 'black power' was Stokeley Carmichael, the leader of an extremist students' organization who alleged that 'black power' was the movement that would destroy everything created by white civilization. Another leader of a radical movement – Floyd B. McKissick – considered the seizure of power as the only way to bring about serious changes in society.

## AFRICAN SOCIALISM

African socialism was widespread on the continent after independence. African leaders of the first generation such as Julius Nyerere, Kwame Nkrumah, Modibo Keita, A. Sekou Touré and Kenneth Kaunda viewed independence as an opportunity to build a new society, free from the colonial legacy. They associated capitalism with colonialism and believed that traditional African society possessed socialist features, including communal land-tenure, large families, kinship ties, a conviction that nobody should starve if others have food, precedence of cooperation over competition and group interests over individual ones. They considered that there were objective prerequisites for the spreading of such a concept: for example they noted that capitalism practically did not take

root in Africa, the bourgeoisie and the working class were 'in embryo' and vast strata of traditional society still remained in rural areas. Under such conditions many leaders, striving to achieve their egalitarian goals and ideas, relied on the state as the only serious force capable of managing the economy and the process of socio-economic decolonization, as well as moulding the self-consciousness of the people and securing the integrity of the nation-state. African socialism differs both from socialism of the Western social-democratic type (L. Senghor, J. Kenyatta) and from 'Marxist-Leninist' regimes (S. Machel and J. Chissano in Mozambique, Mengistu Haile Mariam in Ethiopia, A. Neto and E. dos Santos in Angola, M. Kerekou in Benin), since it does not recognize class struggle, the ideology of Marxism, atheism, etc.

## POPULIST MOVEMENTS AND DICTATORIAL REGIMES IN LATIN AMERICA

During the first decades of the twentieth-century, socio-economic changes in Latin American countries led to an enhanced role of urban areas, industry, the bourgeoisie and the working class. This undermined the dominating position of *latifundistas* (large land-owners), broke the traditional social consensus and led to political destabilization. In the 1930s and the 1940s, in such countries as Brazil or Argentina, a grave structural crisis developed, giving rise to populist regimes and movements. In Brazil, the parliamentary oligarchy of *latifundistas* was undermined by the revolution from above in 1930, and during the subsequent 15 years, the country was ruled by the populist leader, Getulio Vargas. General Juan Domingo Peron, having ousted the military junta, became the absolute dictator of Argentina (1946–55). Both of the populist regimes relied on the support of the middle classes, trade unions and migrants from rural areas and performed two principal social functions: (a) mobilization of the masses against the domination of the traditional oligarchy and clearing the way for national capitalism and (b) opposition to and suppression of extremist political trends (Vargas, for instance, crushed the leftist uprising in 1935 and the fascist putsch in 1938).

After the Second World War, populism tried to carry out import-substitute industrialization in Latin America. However, this strategy did not fulfil expectations. While Latin American countries were trying to catch up with the industrialized countries, the technological revolution in the developed countries propelled them to a post-industrial level. In other words, the dependency remained. At the same time that industrialization gave birth to new social contradictions, mass disappointment, caused by unrealistic expectations, put those countries on the brink of a new structural crisis. In response to the latter, military coups were carried out and bureaucratic authoritarian regimes established in Brazil (1964), Argentina (1966), Peru (1968), Chile and Uruguay (1973). These regimes were different from both traditional caudillo-type and populist dictatorships, and not only because the army came to power as an institution rather than for the sake of installing a new dictator. The principal distinction lies in the fact that these regimes had to solve the complex task of combining ordinary industrialization with post-industrial technological

revolution. It was also necessary to find a 'golden mean' between the previous economic nationalism that characterized the 'catching-up' industrialization on the one hand and the transnational cosmopolitism of the technological revolution's productive forces on the other. Hence the suppression of liberalism and the distancing of the masses from active political life.

## RELIGIOUS AND SECULAR MOVEMENTS IN AFRICA

Political-religious movements were an initial form of protest and organization of African masses. The largest of such movements – Kimbanguism – emerged in 1921 in Belgian Congo (Democratic Republic of Congo) in the form of a Protestant heresy. Named in honour of its founder, the priest Simon Kimbangu, the movement advocated passive disobedience, but when its followers began to refuse to work and to pay taxes the authorities put Kimbangu in jail, where he spent 30 years until his death in 1951. Consequently, Kimbangu acquired martyr status and was considered the 'saviour of the black people' by his followers, who associate him with Moses, Jesus, Muhammad and Buddha. Kimbanguism contributed to the emergence of another, more active anti-colonial movement in Belgian Congo named Kitawaia, which clearly voiced political protest. Both movements were to a certain extent influenced by the 'Watch Tower' movement, which had originated in the United States and transferred at the beginning of the twentieth century to Nyasaland (Malawi) before spreading to Zaire, Zambia and Zimbabwe.

There also existed secular anti-colonial movements. In the Republic of South Africa, Robert Sobukwe, founder of the Pan-Africanist Congress (1959), in 1960 put forward the concept of 'black consciousness'. He placed emphasis on 'black' instead of multi-racial solidarity, insisted on the 'Pan-African' rather than 'South African' nation, and took a more militant position than that of the African National Congress from which he had seceded. After his arrest, the concept of 'black consciousness' was adopted by the South African Students Organization (1969) headed by Steve Biko. The latter developed the concept and brought it to the level of Hegelian dialectics: 'black racism' should be counterposed to 'white racism', and only the conflict-confluence interplay of these two opposites can produce a viable synthesis of ideas and *modus vivendi*.

On the whole, liberation movements, thanks to which developing countries gained independence, were led by nationalists. However, independence did not automatically lead to social and economic self-sufficiency and, in the sphere of culture, foreign influence became even greater. Traditional foundations were destroyed before the new ones were set in place. Beginning in the 1970s, these transformations stirred up a new wave of religious revival. In Senegal, for instance, Murid marabouts expressed the peasants' discontent. In West Africa and the Sahel, numerous religious sects hostile to the ruling elites emerged. In the cities, the principal social base of religious revival was formed by migrants from rural areas, and particularly unemployed youth. New religious-political movements reflected the search for alternative survival strategies. Some of them have seriously challenged the existing regimes (e.g., the Islamic Salvation Front in Algeria).

## POST-COLONIAL REGIONAL AND CONTINENTAL INTEGRATION

For a number of understandable historical reasons, Latin America was the first to undergo the integration processes. However, soon after the Second World War, the United States attempted to conserve its dominant position in the region as well as the existing neo-colonial division of labour by initiating the establishment of the Organization of American States (OAS) in 1948. This, however, did not suit most Latin American countries, and they began to strive for integration without the participation of Western states. In 1960, Argentina, Brazil, Chile, Mexico, Paraguay, Peru and Uruguay established the Latin American Free Trade Association (LAFTA) and were subsequently joined by Bolivia (1966) and Venezuela (1967). As the more developed countries reaped the greatest advantages from LAFTA, the sub-regional Andean pact (Bolivia, Chile, Colombia, Ecuador, Peru and Venezuela) was formed within the framework of the Association in 1969.

In 1968, 11 Caribbean countries created the Caribbean Free Trade Association (CARIFTA). In 1973, they signed an agreement on the Organization of the Caribbean Community and Common Market (CARICOM). This event was significant because it marked the first time the process of integration evolved from a free-trade zone into a customs union (according to the model of the European Community) in the Third World. In the early 1990s, the Southern Cone Common Market (MERCOSUR) was also proclaimed. Its members intend to set up the Common Market and the Customs Union. At the same time, in recent years the concept of 'open regionalism' has become quite popular in Latin America. This was reflected in the results of the 'All-Americas' summit (34 participating states), which took place in Miami (USA) in December 1994. Participants reached full agreement on setting up a zone of free trade in the Western hemisphere by 2005 and progressively joining the North American Free Trade Agreement (NAFTA).

The processes of integration in Africa were even more complex. In 1963, 32 independent African states met in Addis Ababa to approve the Charter of the Organization of African Unity (OAU). This organization made an outstanding contribution to the processes of decolonization, the struggle against apartheid and neo-colonialism and African economic development. It went through periods of crisis in its development (particularly in the early 1980s) but managed to overcome them successfully and to remain the main exponent of African solidarity (Plate 48).

As to sub-regional integration processes, they were rather unstable until recently. Two noteworthy examples are the Central African Customs and Economic Union (UDEAC), established in 1966, and the East African Community (1967), which existed for only ten years. Attempts to consolidate the Economic Community of West African States (ECOWAS), which was formed in 1975 by 16 English- and French-speaking countries, were unsuccessful. Seven French-speaking countries (Burkina Faso, Côte d'Ivoire, Mali, Mauritania, Niger, Senegal and Dahomey, present-day Benin) set up their own Economic Community of West Africa within the framework of the ECOWAS. Recently the Economic and Monetary Union of Western Africa was finally established, however the Southern Africa Development Coordination Conference (SADCC), an organization set up in 1980 by Angola, Botswana, Lesotho, Malawi, Mozambique, Tanzania, Swaziland, Zambia and Zimbabwe, was much more effective. The collapse of the apartheid regime in South Africa will facilitate the integration of South Africa and Namibia into the southern African development community.

The first attempt at integration in Asia was not very successful. In 1964, Iran, Turkey and Pakistan formed the Regional Cooperation for Development. The revolution in Iran blocked the organization's activities, and, it was finally revived in 1985 as the Economic Cooperation Organization. In November 1992, the membership of the organization increased owing to the admission of Afghanistan and the former Soviet republics (Azerbaijan, Kazakhstan, Kirghizstan, Tadzhikistan, Turkmenia, Uzbekistan). In 1967, Indonesia, Malaysia, Singapore, Thailand and the Philippines founded the Association of South-East Asian Nations (ASEAN), but real cooperation started in 1970 (Brunei joined in 1984). Today it is the most effective and dynamically developing community in Asia, and it is likely to increase its membership at the expense of Indochina and Burma. In 1985, seven countries officially founded the South Asian Association for Regional Cooperation (SAARC). However, political differences between its principal participants constitute a significant hindrance to its successful activity. Nonetheless, the general framework of the Agreement on Preferential Trade Areas in South Asia was drawn up in March 1993.

## OLD AND NEW FORMS OF VIOLENCE

Violence has always been a part of everyday life in Third World countries. Colonialism itself was a synonym of violence, and liberation often began with revolutionary violence. During the first decades after the Second World War, violence was most often provoked 'from above' by belligerent leaders and organizations. For instance, the civil war in Colombia (1948–53), in which about 2 per cent of the population perished (mostly from the rural areas), was provoked by the clashes between the conservatives and the liberals in Bogotá, which, in their turn, were triggered by the assassination of the leader of the liberals. In 1965, clashes between the leftist forces and the right-wing generals in Indonesia escalated into a massacre that took the lives of about one million people. In Kampuchea, factional struggles between its leaders resulted in the genocide of entire social strata and groups of the population. In Rwanda and Burundi, ethnic conflicts between the Hutu and the Tutsi were often provoked by radical nationalist groups belonging to both sides. From 1993 to 1995 alone, approximately a million people were massacred in those clashes.

However, in the 1980s and 1990s, the phenomenon of mass violence resulted for first time from socio-economic, demographic and ecological considerations rather than factors related to ethnic, confessional and political fragmentation. The pauperization of the peasantry, the massive migration to the cities and the emergence of vast urban zones of poverty, high unemployment rates, the marginalization of entire social strata, the growing number of drug addicts, the spreading of numerous epidemics – these are some of the causes of new forms of violence, such as the formation of street gangs, drug rings, gambling groups

and organized crime networks, killing and the destruction of property. Such violence reigns in the streets and highways of Nigeria, Uganda, Zaire, Liberia, Sierra Leone, Ethiopia and Somalia. The major social base of such forms of violence is constituted by the destitute masses of migrants who lost their traditional way of life and were not able to adjust to the environment of quasi-modernized cities. They consider their involvement in criminal violence not as a step down to the 'bottom' of society but as a rise in their status. They perceive violence as the only attainable form of freedom.

New forms of violence are particularly dangerous because of their spontaneity and unpredictability. They do not have slogans or programmes. Violence in such cases is not a means but an end in itself and leads to criminal anarchy. In many cases, old and new forms of violence are superimposed and intertwined thereby further increasing violence. This phenomenon occurred on a large scale in Iran for the first time in the course of struggle against the monarchy. In Algeria, traditional confrontation between the Islamic fundamentalists and the authorities was reinforced in recent years by new social forces (migrants and unemployed young people from urban areas) and became the source of everyday mass violence and killings. In Pakistan, traditional contradictions between the Muhajirs (immigrants from India) and the local population, as well as between the Sunnites and the Shi'ites, became particularly explosive because of an inflow of migrants and refugees from Afghanistan to the cities (especially Karachi).

Today, unsolved national-ethnic, national-state and other problems are projected onto the world community in the form of international terrorism (hijacking of planes, capturing of ships and other transportation vehicles, hostage-taking, assaults on embassies and diplomats, bombings in the cities of Western countries, etc.). Moreover, today violence has reached a qualitatively new technological level. Terrorists are equipped not only with Kalashnikov sub-machine guns but with chemical weapons and electronic devices as well. World powers, which uncontrollably stockpiled arms in the Third World countries during the Cold War, also bear responsibility for this new level of violence.

## NEW COUNTRIES AND WORLD POLITICS

*Iba Der Thiam*, coordinator

# INTRODUCTION

*Iba Der Thiam*

The twentieth century has been marked by a series of events, deeds and changes whose scale, scope and consequences will surely be considered impressive by any standards. Not only did the first half of the century witness two world wars – with the resulting lost lives, physical destruction, psychological trauma and moral damage – in which humankind reached an unprecedented degree of barbarity (poison gas, the Holocaust, nuclear bombs on Hiroshima and Nagasaki), it also saw the world's first communist regime, whose birth was symbolized by the 1917 October Revolution and followed by a worldwide communist movement culminating not only in the triumph of Marxism-Leninism in China after the war against the Kuomintang and the Long March of Mao Zedong, but also in the New Deal in America and the Popular Front in France. The period was also marked by the roaring twenties, the beginnings of radio broadcasting, advances in motor and aircraft design, a proliferation of the press, the vote for women and progress, exemplified by the creation of the League of Nations and the building of a world order founded on peace, security, democracy, and justice – all of which fostered the rise of nationalism in the Arab, Asian and Latin American countries.

The impact of these changes would inevitably affect science, technology, education, culture, lifestyles and values. In the course of this period, after the years of economic recovery immediately following the First World War and the empire-building projects launched by the colonial powers, the world moved into a phase of deep economic depression resulting in widespread bankruptcy, unemployment, the development of Fascism in Italy, Nazism in Germany, militarism in Japan, and nationalism in the Middle East, Asia and Africa.

From this general climate arose some of the most potent causes of the Second World War; and the deeds and consequences of that war weighed so heavily on the course of events in every way that they radically transformed the existing order and marked a clear break with the past. Although the birth of the United Nations Organization (UN), the Universal Declaration of Human Rights, the Bretton Woods institutions, the Marshall Plan, the Brazzaville and Bandung conferences, Indian independence,

and the birth of the Federal Republic of Yugoslavia and the Non-Aligned Movement all represent undeniable and significant advances, progress was curtailed by the division of the world into the two blocs of East and West and the ensuing Cold War, the Berlin Blockade, wars in Korea and Indochina, the armed national liberation movements in Asia and the Arab world, the institution of apartheid, the Thiaroye Massacre in Senegal, and the incidents with French colonial power in Dimbokro and Seguela in West Africa, the Mau-Mau Insurrection in Kenya, and the Algerian War of Independence.

The tensions of this new phase were to prove all the harder to manage as ideas travelled faster with innovations in communication (radio, television, press). Science was making unprecedented strides: the conquest of space; progress in medicine, biology, physics and chemistry; a revolution in land, sea and air transport; improvements in living standards (televisions, refrigerators, automobiles); and the flourishing of the consumer society.

Agriculture, industry, the arts and crafts, literature, music, records, cinema, sports, leisure, work, social life, and urban development all underwent changes of an extraordinary scope and variety, radically altering practices, traditions, customs, the way people thought and behaved, and their aspirations and expectations. The arrival of the new independent African states on the international scene upset the existing international order and brought new challenges to the relationship between North and South: unequal exchanges, unfavourable terms of trade, debt, poverty, and demands for a new, fairer international economic order, the democratization of international relations, a new world information and communication order, and the creation of mechanisms to regulate trade, commerce, and tariffs (e.g., GATT).

Under the impact of successive oil shocks related to conflicts in the Middle East, the world crisis that followed the rise in the price of crude oil, American interest-rate policies, and erratic swings in the value of the international currencies, the economies of the poorer countries, which had experienced a euphoric growth phase in the 1960s, began to show signs of weakness by the late 1970s and were finally overwhelmed by the burden of their debts and forced

to adopt structural adjustment plans whose social consequences were dreadful.

The 1980s have come to be regarded as a lost decade, especially for Africa where growth ebbed and outright poverty increased. All macro-economic indicators showed downward trends: education, health, and employment underwent deep and lasting structural crises.

It was not until the fall of the Berlin Wall, the end of the world communist movement, and the absolute supremacy of the United States that new energies were released by a new world order based on market economics and pluralism in democratic government and in the media. Nationalism, terrorism, and tribal, ethnic, and religious wars erupted within national borders; and as the world entered the twenty-first century, it began a new stage of fundamental rearrangement. In the field of science, the information revolution, progress in the conquest of space, advances in medicine and genetics, and increasing concerns about the environment (ozone layer, inadequate water resources) have opened up new fields of research and activity. International relations have become more and more unbalanced, and the North has increased its technological, scientific and economic lead over the South.

Although new centres of growth have appeared in Asia, new states are emerging in Latin America, and Africa has experienced growth again in the 1990s, these signs are still too fragile for us to claim they constitute a strong or lasting trend as revealed by the Mexican crisis and the Asian stock-market crisis.

# 7.1
## RELATIONS BETWEEN INDUSTRIALIZED AND INDUSTRIALIZING COUNTRIES

*Nodari A. Simonia*

Among the most urgent tasks facing Asian, African and Latin American countries after independence were achieving economic independence and becoming integral and equal participants in the world economy. However, attaining these objectives proved to be a rather long, difficult and uneven process. A wide range of exceptions to free-trade principles were agreed upon between the old colonial powers and the newly independent countries, but this favoured treatment and the high hopes it generated were gradually eroded as illustrated by the Lomé Convention, a partnership between 70 ACP (African, Caribbean and Pacific) countries and the European Union. The most important aspect of the Lomé 'aid and trade' pillar was the provision for preferential access to European markets for ACP exports. Despite this advantage, most ACP countries have not be able to make progress in economic terms, and their market share actually declined from 6.7 per cent in 1976 to 3.4 per cent in 1993.

Within the framework of the confrontation between two systems (and two superpowers), the majority of developing countries chose to join the Non-Aligned Movement to resolve their problems of political sovereignty and achieve self-sustaining economies. Many countries went through a stage of 'revolutionary romanticism' hoping that radical political action could solve economic problems and create a 'New World Economic Order'. This phase was characterized by import-substitution strategies, as well as outbreaks of isolationism in some parts of the Third World. Although a number of 'oil shocks' in the 1970s and the early 1980s marked significant achievements in this struggle, they also revealed the limits of such successes and an undeniable interdependence between industrial and developing countries. Since then, a succession of challenges – debt shocks, threats to the world financial system – has reinforced our awareness that the welfare of all countries, whatever their level of development, is evermore closely interlinked. However, this interdependence was asymmetrical, and in essence, remains so since developing countries are more dependent than industrial countries.

Since the 1980s, there has been a serious shift towards pragmatism in the economic strategies of developing countries, which have considerably intensified since the end of the Cold War. The adoption of market-based, export-oriented economic development strategies by a wide range of developing countries represents a fundamental shift in their thinking about development and about the basis for participating in the world economy. The commitment of an even wider range of countries (including not only Eastern and Central Europe, Russia and the other former Soviet Republics, but also the more dynamic Asian and Latin American economies) to full participation in the global economy, and the impact of this globalization, will bring new opportunities and new relationships to the international division of labour.

In the 1990s, the developing countries registered a noticeably higher economic growth rate (6 per cent in 1995) than the industrial ones; and their exports and imports grew faster than world trade as a whole. Yet, there were growing disparities both within and among these countries. What appeared to be a relatively homogeneous Third World in the early 1960s is now a highly diverse group of countries and regions. Some developing countries are now achieving considerable rates of growth and impressive reductions in poverty; many have advanced so rapidly during recent decades that they are on the point of 'graduating' to the ranks of high-income industrial countries. While the majority of developing countries have grown more slowly, they have still done well compared with developed countries at a similar stage in their growth, and their standards of living have greatly improved.

In Asia, particularly, the emergence of China and India onto world capital markets has been a major new factor. Once again, their development has been based on a commitment to outward-looking, market-oriented policies, and on the prospects investors now see in these potentially giant economies. Both economies have enormous resources of human capital, but they also have large groups of people living in poverty or sub-standard conditions, and they face major social and environmental challenges.

Other developing countries have been increasingly marginalized from the global system and suffer continuing deterioration in already deplorable living standards: they include much of sub-Saharan Africa and certain countries in Latin America and South Asia. For many years, these

poorer countries will continue to be dependent on aid, reproducing dangerous patterns of aid dependency. In 1965, the average per capita income in sub-Saharan Africa was 60 per cent of the average in developing countries. By the late 1990s, the figure was less than 35 per cent, despite the many high-profile efforts launched repeatedly since the 1960s to support African development.

Tremendous changes have taken place in the geopolitical scene since the collapse of the Berlin Wall in 1989: the disintegration of the USSR and of the former Yugoslavia, ethnic strife in these territories, widespread suffering and dislocation of populations have made it evident that ethnic violence, a need for humanitarian relief, and formidable challenges of reconciliation and reconstruction are by no means confined to the developing world. Today, there remain significant challenges such as more comprehensive reforms, the maintenance of stability, and the reform of institutions and behaviour in Eastern and Central Europe and in the Commonwealth of Independent States (CIS). So far, only the 'fast-track' reforming Central European and Baltic States have reached – or almost reached – the steady 4 to 6 per cent annual growth needed to reduce the gap in living standards that separates them from other industrial countries. Only Poland has recovered its pre-1989 gross output levels. In the Central Asian republics of the former Soviet Union, now regarded as belonging to the group of developing countries, the Soviet-era economic and political system has created a legacy of serious environmental problems that will not be quickly or easily rectified and will adversely affect future development and public health.

## INTERDEPENDENCE AND INTERNATIONAL COOPERATION

### Official Development Aid (ODA)

Development is not an isolated objective, and development cooperation through financial and technical assistance is only one of many factors that substantially affect relations between developed and developing countries and that may significantly improve the economic, institutional and human development capacities of the latter group. Cooperation within the United Nations, the international financial institutions, the OECD (Organisation for Economic Co-operation and Development) and other global and regional organizations has greatly enhanced these efforts and shaped an evolving multilateralism in which all countries hold a vital stake. In those countries where aid has coincided with an adequate, constructive national strategy for development, the impact on growth has been positive. Overall, however, foreign aid to developing countries since 1970 has had no net impact on either the recipients' growth rate or the quality of their economic policies, according to an internal World Bank study (*Financial Times*, 14 April 1997). Positive reform has largely been the result of domestic forces.

Clearly, the shared objective of human security, combined with respect and concern for others, has not yet brought sustainable development to a position of central importance on the international agenda. Budgets have been much tighter in the donor countries, resulting in many cases in cuts in appropriations for development assistance. The end of the Cold War has removed the traditional security

rationale for development cooperation. Increased opportunities for productive collaboration have been threatened by a reduced sense of urgency manifested by a diminished political commitment and related financial resources. The so-called 'peace dividend' has not materialized.

Of course, there is no guarantee that state intervention will benefit society. Some developing countries do not meet even the most basic requirements for sound economic management. The major obstacles to development are arbitrary government action, bureaucratic corruption (bribes, abuse of patronage, etc.) and inefficiency. Some developing countries still lack the most basic underpinnings of a professional, rule-based bureaucracy, and the opportunities for sinecures and corruption are considerable. According to a large-scale survey, the *World Development Report* prepared by the World Bank in 1997, almost 80 per cent of entrepreneurs in Latin America, sub-Saharan Africa, the CIS, and Eastern and Central Europe reported a lack of confidence in the authorities' readiness or capacity to protect their persons or property. Another survey confirmed that corruption remains a widespread problem for investors. A corrupt bureaucracy that is allowed too much discretion creates incentives that divert capital towards *rentier* investments rather than productive activity. Overall, problems associated with uncertain property rights and dealing with arbitrary power (corruption and crime) rank among the top three obstacles in developing countries and emerging market economies.

Recent years have witnessed a growing convergence in thinking about the new rationale and objectives for development cooperation. The emerging framework for this cooperation is that development partners should try to help countries improve their capacity to participate in the global economy and should assist people in improving their capacity to overcome poverty and to participate fully in their societies. In 1996, the Development Ministers and Heads of Aid Agencies of the OECD's Development Assistance Committee (DAC) decided to consolidate this broad conceptual agreement. They adopted a new strategy for the twenty-first century that included a bold proposal for global partnership for locally owned, people-centred sustainable development. However, effective implementation proved to be fraught with obstacles. After remaining at around 0.35 per cent of DAC members' GNP for well over 20 years, DAC countries' collective ODA effort has fallen to just 0.27 per cent, its lowest level since the United Nations adopted a 0.7 per cent target in 1970. In 1995, only Denmark, the Netherlands, Norway and Sweden achieved the United Nations goal, and only Denmark and Japan had increased their ODA expenditure since 1992. Between 1992 and 1995, net ODA fell by 14 per cent in real terms – the sharpest three-year drop since the early 1970s.

### Private financial flows

In the mid-1990s, the overall picture of financial flows to developing countries was radically transformed: private flows to the larger and more dynamic economies began growing most rapidly, while the volume of official flows to the smaller and poorer countries – the ones most in need of financial aid if they are to attain the capacity for sustainable development – is declining. These diverging trends cast a

shadow on the credibility of a development partnership strategy and their continuation could have grave consequences.

Measured in constant dollars, total net flows of ODA received by developing countries have remained stable in the range of US$55–60 billion since 1986. In current dollars, ODA increased from US$56.7 billion in 1987 to US$69.4 billion in 1995, but as a percentage of the total net flow of resources to developing countries, ODA declined over the same period from 66.1 per cent to 28.3 per cent, while private flows increased from US$30.7 billion (35.8 per cent) to US$158.9 billion (67.4 per cent). Net private capital flows increased in 1996 for the sixth year running, surging to a record US$243.8 billion; but most of the money bypassed the poorest countries. These private flows are highly concentrated: among the top twelve destinations for private capital were four from East Asia (China, Malaysia, Indonesia, Thailand) and four from Latin America (Mexico, Brazil, Argentina, Chile). The top twelve recipients together accounted for 72.5 per cent of overall private inflows. No wonder, then, that the World Bank recently admitted (*Annual Global Development: Financial Report*, March 1997) that private capital is not a substitute for ODA targeted at programmes aimed at promoting health, education and environmental protection.

### Non-governmental organizations (NGOs)

In some developing countries, especially in Africa, one of the major changes has been the recognition that in development issues the state does not have to be the donor agencies' only interlocutor. However, if a strengthening of capacities does not support the decentralization which is flowering in many Third World countries, it will soon perish. NGOs from developing and industrialized countries can play a key role in this process. In general, NGOs are flexible and efficient; they work at grass-roots level and are familiar with the needs of local populations. They may help to set and monitor standards and inform the world community of social or environmental damage. There is general agreement that NGOs must play larger and more prominent roles in education: they can be of assistance as advocates, sources of funding, intermediaries for managing assistance, and local programme implementers. Many of the most responsive local organizations and programme initiatives have features promoting health, nutrition, or other benefits in addition to educational ones. Programmes initiated or managed by NGOs appear to have significant advantages, both in their responsiveness to local needs and in reduced administration and other overhead costs. One major development is the growing maturity of developing countries' own NGOs, which tend to play a more important role in articulating the needs of the poor in their communities.

NGOs have emerged as prominent partners in the development field. By the early 1980s, virtually all DAC members had adopted some system for co-financing projects implemented by their national NGOs. Net grants by NGOs (net disbursements, at current prices and exchange rates) have risen from US$2.39 million (3 per cent of total financial inflows) in 1980 to US$5.97 million (4 per cent) in 1999. However, some NGOs feel that they are being used only as cheap delivery systems. Rather than simply filling gaps, they want to sit at the table. In its capacity as Secretariat of the Committee of International Development Institutions on the Environment, UNEP (the United Nations Environment Programme) provides a link between the DAC Working Party and most major international organizations concerned with environmental matters. In addition, three international NGOs – the International Institute for Environment and Development (London), the International Union for Conservation of Nature (Gland, Switzerland), and the World Resources Institute (Washington, DC) – have been invited to participate regularly as observers.

### 'NEGATIVE INTERDEPENDENCE': GLOBAL PROBLEMS

Along with the increasing trend towards economic interdependence and integration, the world community is confronted by the challenge of growing 'negative interdependence' caused by various global problems threatening developed and developing countries alike. Problems related to the quality of water, soil and air; acid rain; climate change caused by the greenhouse effect; loss of biodiversity; depletion of fish stocks; current patterns of production and consumption – all raise questions about the future capacity of the Earth's natural resource base to feed and sustain a growing and increasingly urbanized population. Industrial countries increasingly recognize that the solution to such problems is no longer solely in their hands and that the management of global issues in the twenty-first century will require the active participation of all members of the international community.

### Energy problems

Availability of sufficient low-cost energy is indispensable for growth in developing countries as well as in industrialized countries. Reconciling the energy needs of different groups of countries may generate particularly difficult policy challenges in the very near future. Fossil fuels now account for 80 per cent of the world's drastically increased energy consumption. The geographical distribution of energy sources is very uneven. In 1995, OPEC countries possessed 778.2 billion barrels of known oil reserves; 103.9 billion barrels were in the OECD group, 57 billion in the territory of the former Soviet Union and 77.8 billion in other countries. On the demand side, OECD countries consumed 50 per cent of world energy in 1986, all developing countries 27 per cent, and the centrally planned economies 23 per cent.

Two acute problems are already evident today: (1) demand is growing faster than expected; and (2) the centre of gravity of the world's oil markets is shifting rapidly eastwards, to the fast-growing economies of China and South-East Asia. Recent studies indicate that every Asian country except Brunei will be a net oil importer by 2015. (China, one of the biggest energy consumers in Asia, has recently turned the corner and become a net oil-importing county). In India, another major energy-consuming country, economists estimate that power shortages cost Indian industries US$2.7 billion annually, equivalent to 1.5 per cent of the country's GDP.

A crucial issue for developing countries is the future of nuclear power, which may conceivably become a major

supplier of energy. Today, Argentina, Brazil, India, Pakistan and South Korea already have nuclear capacity, which accounts for a significant part of their electricity production. However, this subject raises an important question: Can energy sufficiency be achieved safely, without environmental contamination and without the danger of nuclear war or nuclear terrorism? Some experts argue that 70 years will be needed before the Chernobyl 'tomb' is safe. In any case, wind, solar, tidal energy and other clean and safe alternative sources must be seriously considered.

## Ecology

There is growing concern about a number of global-scale types of environmental degradation. The build-up of greenhouse gases creating a one-way thermal barrier with the risk of global climate change is one of the most serious potential threats. It is largely related to the use of fossil fuels. As a result, carbon dioxide concentrations in the air have increased by some 30 per cent over the past two centuries, and the average temperature has risen by 0.3–6 °C over the past century. Industrial countries have been a major source of greenhouse gases: in 1985, OECD countries were responsible for approximately 46 per cent of global carbon dioxide emissions (North America accounts for 25 per cent, Europe 15 per cent, Japan and the Pacific region 6 per cent). The centrally planned economies' share was 26 per cent, and that of all developing countries together was 27 per cent. Despite the work accomplished at the Earth Summit in Rio de Janeiro in 1992, the treaties to protect the atmosphere were still foundering by the end of the century, and annual emissions of carbon dioxide from fossil fuels have climbed to an all-time high, altering the very composition of the atmosphere.

Developing countries are also concerned by this situation, both as sources of global environmental degradation and as potential victims. According to a World Watch Institute report (January 1997), the United States' share of world carbon emissions today is 23 per cent. China comes second with 13 per cent, Russia produces 7 per cent, Japan 5 per cent, Germany and India 4 per cent each, and Indonesia and Brazil each generate 1 per cent.

Tree felling and burning, and deforestation in general, are other sources of carbon dioxide emissions. Burning forests produces carbon dioxide as a one-off effect, but in addition the burned forests stop absorbing carbon dioxide and acting as 'lungs' for the Earth. According to an FAO study (March 1997), our planet lost an average of 15.5 million hectares of forest each year between 1980 and 1990. Only 20 per cent of the world's major virgin forests remain, almost all in the far north of Russia and Canada, and in Brazil's Amazon region (World Resources Institute, March 1997). Another negative result of deforestation is desertification, which has reached disaster proportions in Africa.

Major national and international actions and initiatives have been launched to address global environmental issues. The United Nations Environment Programme, together with other international institutions, has an important role to play in organizing action in this field. UNEP coordinates the United Nations Plan of Action to Combat Desertification: the countries of the Sahel have elaborate plans forming a framework for these actions. In an effort to protect the ozone layer, whose depletion is causing serious health hazards (skin cancer and eye diseases), the Montreal Protocol of 1987 was strengthened in May 1989 by an agreement, supported by 80 countries at the Helsinki UNEP Conference, to end all production and consumption of CFCs by the year 2000. The 1992 Rio Summit gave momentum to consideration of the problem of the global environment in all its complexity and provided an opportunity to review the many initiatives already undertaken as part of a global strategy. Under a Climate Change Convention adopted at the Rio Summit, developed countries were to reduce their greenhouse gas emissions to 1990 levels by 2000. To avoid a loophole in this convention, a crucial conference held at Kyoto (Japan) in December 1997 set legally binding targets for industrialized countries to cut their emissions of these gases after 2000. However, the effectiveness of the Kyoto Protocol was seriously undermined when United States President George W. Bush refused to sign the agreement in 2001.

In the case of the developing countries, it is generally recognized that uniform environmental standards may not be practical, economical, or politically viable for many of them. Agenda 21, the comprehensive plan of action adopted at the Rio Summit recognized that environmental standards valid for developed countries might bring unwarranted social and economic consequences in the developing world. The North should do more to help the South in using environmentally sound technologies, practices, and products, for example those that incorporate energy efficiency and pollution-control criteria. Developed countries could make a great contribution through cooperation and partnership with developing countries in the field of environment-friendly technology. Environmentally sustainable ODA must become the norm.

## The population explosion

In many developing countries, combating poverty and solving environmental problems are made more difficult by continuingly rapid population growth. In some cases, population growth rates are too high to permit sustainable development. It is estimated that population growth in the developing countries will account for virtually all the increase in the world's population from 5 billion in 1990 to about 7.5 billion in 2015. This increase over 25 years is roughly equal to the total human population in 1950. The population explosion is therefore one of the enormous challenges to be faced by the developing countries: the prospect carries severe economic, environmental, social, and political implications. Many developing countries will have tremendous problems coping with the doubling or even tripling of their populations over the next few decades. Acute situations are projected in sub-Saharan Africa, where population growth will be greatest and the capacity to cope is weakest. Most Islamic countries face a population explosion, which will greatly exacerbate the challenges of political and economic modernization. The population of India is projected to increase by over 600 million by 2025 (to 1.45 billion), while Pakistan and Bangladesh could more than double in size to well over 250 million each. Even advanced developing countries such as Brazil and Mexico face the task of absorbing huge population increases, and an increasing number of mega-cities are appearing in all parts

of the developing world, with their attendant social, political, and environmental challenges (Plate 49).

In its early years, 'development' was discussed and planned with little reference to demographic factors. At the 1974 World Population Conference in Bucharest, the world community first acknowledged the determinant role of population factors in development and the need to curb population growth rates. According to WHO estimates in the late 1980s, about 300 million couples who did not want more children were not using any method of birth control. As discussions at the Rio Summit underlined, any delay in adopting appropriate population policies will exacerbate the situation. The 1994 Cairo Conference on Population and Development resulted in effective action towards making voluntary family planning available to more couples.

Along with high population growth in the poorer countries come rapid urbanization and increased pressures on soil, water, forests, and air. These pressures are evident in all regions, but their specific manifestations vary, as do the capacities of countries and regions to cope. These negative tendencies are also reflected in the growing problem of international migration: as wealthy countries around the world face a growing influx of illegal immigrants and refugees, many are turning to military force to stem the flow.

### Water supplies

According to United Nations reports (March 1997), water shortages – which currently affect about 40 per cent of the world's population – will become increasingly frequent in the twenty-first century and can be expected to reach crisis proportions by about 2030, due to a combination of population growth and pollution. Today, some 80 countries experience serious shortages. About one-fifth of the world's population has no access to safe drinking water, and approximately one out of every two people lacks adequate sanitation. Even in relatively wealthy Europe, there are some 110 million people without access to safe drinking water. Water-borne diseases that had been considered eradicated, such as cholera, have reappeared in some former Soviet republics. The Aral Sea in Central Asia – once the world's fourth largest lake – is shrinking: four decades ago, about 60 cubic km of fresh water flowed into the Aral every year; now only 1–5 cubic km trickles through annually, depending on the rainfall. Experts describe water supplies as one of the main challenges of the twenty-first century, a view echoed by the World Water Council, which organized the World Water Forums attended by scientists, bankers, United Nations and other officials from five continents. Speaking at the First World Water Forum in Marrakech (Morocco) in 1997, UNESCO's Director-General, Federico Mayor, said: 'To provide for foreseeable future needs, water resource development and management must be placed at the top of national and international agendas as part of a global strategy'.

With some 300 major river basins extending across national boundaries, future conflicts over their water constitute a serious potential risk. Some United Nations officials believe that over the next 50 years water could replace oil as a principal cause of major conflicts between countries and peoples. Indeed, as water supply emerges as a key factor in many regions of the world, it is becoming an increasingly prominent political issue. In North Africa, where urbanization is drawing most of the population to the coastal regions, and in the Middle East, where competition is intensifying for what is mainly a single, interconnected water system, water is the key resource issue and is fast becoming a crucial point on the region's political agenda. Water can therefore either become a cause of conflict or a catalyst for regional economic and political cooperation.

### OBSTACLES TO THE SEARCH FOR A NEW WORLD ORDER

Now that the Cold War is over, confusion seems to reign concerning what happens next in the new millennium. The world is clearly in transition since the collapse of the Berlin Wall, but the following question inevitably arises: how might the fabric of the world economy be woven in new ways? Too many in the West assume that the answer lies in the ongoing process of globalization: they believe that economic globalization is inevitable and that nothing can be done to shape its social consequences. On the basis of these assumptions, they insist that developing countries must dismantle their protectionist barriers to accelerate liberalization and allow foreign institutions to compete more freely for business within their borders. They assume that globalization of the economy is leading to increased wealth; but that is only one side of the story. The other side is that we are now witnessing greater divisions and inequalities within and between societies, accompanied by uncertainty and even scepticism about the present models of international cooperation. Today the 350 wealthiest moguls have as much money as the poorest 3 billion people. The UNDP 1996 Human Development Report from the notes that the poorest fifth of the world's population saw its share of global income decline from 2.3 per cent to 1.4 per cent in the past 30 years, while the share of the richest fifth rose from 70 per cent to 85 per cent. So, the following question arises: does globalization hold the best answer to the problems arising from the process of transition to the new world economic and social order?

### Globalization

It is undeniable that globalization can lead to numerous economic and scientific achievements. But even in some highly developed Western countries, there is unease and anxiety that the economic and cultural price of globalization may be too high. The most painful dilemma involves the manner in which their national identity can be protected. In the case of most developing countries, globalization has been met with fiercer resistance because it puts much more severe pressure on local institutions and traditions in their societies. While it has been generally acknowledged that globalization has had a certain positive impact on some developing countries, especially advanced ones, certain aspects must be viewed with alarm. The developing countries generally are conscious of being at the receiving end of globalization. They are concerned that it may become a Western-dominated process and dilute efforts towards nation-state building – a process that most developing countries have not yet completed. It is also

feared that globalization may prove incompatible with efforts to strengthen regional groupings, which has proven very useful for small countries. Furthermore, it cannot be denied that there are certain sectors of society and certain countries that have been marginalized: this was acknowledged in the final communiqué of the G-7 Economic Summit in 1996. Given the swift pace of globalization and the speed with which products and markets now evolve, countries and groups that are slow to integrate will find it increasingly difficult to catch up with the rest of the industrialized world, and so globalization clearly involves a risk that entire countries and regions may be left behind. Kofi Annan, Secretary-General of the United Nations, speaking in February 1997, at the World Economic Forum in Davos said: 'Globalization in itself cannot be seen as a magical panacea. The benefits of globalization are not always apparent to the poor, the hungry and the illiterate.'

Even the newly emerging and rapidly developing countries are worried in the face of evidence that Western industry is primarily focused on gaining better access to high-flying economies in Asia and Latin America, and although these countries have lowered barriers to imports and foreign investment in manufacturing and infrastructure, they have been much more reluctant to liberalize their financial services. Even some countries that accept the economic case for liberalization are unwilling to be seen to yield to external pressure – all the more so when much of it is generated by powerful foreign institutions eager to muscle in on their markets. Furthermore, some developing countries are asking why they should go along with a deal that offers them no advantages in terms of their exports. They doubt that the major industrialized countries are really willing to fully open their markets to the exports of the developing world, as required of members of the World Trade Organization. Is business in the developed countries really prepared to accept the structural changes brought by liberalization? It is clear, then, that there are many sensitive questions connected with globalization, and their answers will determine the nature and quality of society in the twenty-first century.

## The World Trade Organization (WTO)

The Uruguay Round of trade negotiations (1986–94) involved a difficult struggle to balance different interests across a wide range of issues. Its successful completion and the creation of the World Trade Organization (WTO) in 1995 marked another important step towards launching a 'New World Order' in trade. While the WTO has inherited many characteristics from the General Agreement on Tariffs and Trade (GATT), it also features some innovations. Unlike GATT, the WTO was set up as a permanent international agency with a reinforced capability for handling trade disputes. The WTO's dispute-resolution mechanism has been strengthened so that the process can be triggered automatically, and no country, however big, can veto adverse rulings. Since WTO began its work in 1995, internationally agreed regulations have been extended for the first time to agriculture, trade in services, textiles, and the protection of patents, copyright and trademarks. The WTO now provides a multilateral forum for negotiations on these vitally important sectors of global

commerce, and its existence has fundamentally altered the way in which countries address their concerns about the practices of their trading partners. Developing countries have been among the most active in shaping these new norms for expanding trade: their participation in global negotiations and the market-opening reforms that many are adopting have given them new international influence and a new stake in a functioning world economic system.

The creation of the WTO is hardly an end in itself, but only the beginning of a long and controversial process. At present, the WTO needs to make real progress in setting clear priorities for the global trading system. Developing and developed countries try to set different agendas and priorities. The difficulty in striking the right balance is highlighted by the unresolved controversy over proposals to extend the WTO's role well beyond the assault on trade barriers at national borders to include the harmonization of domestic regulatory policies. Such controversies surfaced during the WTO Conference in Singapore (December 1996), attended by 128 member states and 30 observers. The WTO's twin concerns – free trade and sustainable development – had given rise to disagreement on how to strike the proper balance between them. Although industrialized and developing countries shared the view that cross-border investment is a vital source of future economic growth, the two sides remained far apart over the drafting of rules to promote such investment. There were also fierce disputes over human rights and the extension of standards for labour protection. Opposition to these reforms was led by Indonesia, Malaysia, Egypt, Tanzania, Brazil, India and Pakistan. Developing countries consider these Western proposals a thinly veiled form of protectionism, fearing that such proposals, if accepted, would undermine their main comparative advantage in world trade: cheap labour. They argue that their economies – and their workers – would be worse off under such rules.

Of course, the tug-of-war over the WTO's future direction is due in large measure to its membership, which includes developing countries and already-developed ones with different national policies. Nevertheless, there is an extremely pressing need to halt the international frictions that arise from the spread of industrialization and its technical advances. A certain degree of protectionism for developing countries during the takeoff period is inevitable and justifiable, for similar measures were once widely resorted to by today's developed countries in the early stages of their own process of industrialization. Efforts should be made, therefore, to build a liberal economic order that makes possible the coexistence of different types of market economies. This is admittedly a formidable task, but the alternative is trade wars.

## The new world order in information and communication

With the invention of transistors in the 1940s, the modern era of solid-state electronics was born, thus paving the way for our portable radios and phones, pocket calculators, computers, CD players and a plethora of other handy gadgets that we now take for granted in the Information Age. In the past, a country's competitiveness was determined primarily by the productivity of its industries. But in this era of computer networks and advanced information

technology, national competitiveness will be decided by easy access to high-quality information. The accelerating trend towards a more integrated, competitive and interdependent global economy is receiving further impetus from a veritable revolution in the efficiency of communication, i.e., the spreading of information and technology at progressively lower cost and greater speed. At the beginning of the twentieth-first century, an information revolution is in progress, prompted mainly by computer technology and genetic engineering – the so-called third Industrial Revolution. Even an advanced industrial country can be driven into an inferior position within a short time if it allows its technological inventiveness to fall seriously behind. Computer-controlled production and processing will inevitably, by its wide diffusion and ever-advancing technology, bind more and more countries into close relationship. As a result of new developments in information processing, communications, and transport, there has been a progressive expansion and intensification of mobility and knowledge and, with these, a greater mutual economic penetration among countries.

One of the results of the information revolution is that we now have the means of knowing far more about people in other countries. Of course, the number of people who make active use of the information revolution is still fairly limited. Like the new forces of global economics, the globalization of knowledge is geographically restricted, and even the simpler benefits are not available in many parts of the Third World. Two-thirds of the world's population has never made a phone call, and about one out of every two persons has no access to a telephone. In October 1996, International Data Corp. (United States) compiled an 'Information Imperative Index', intended to rank countries by their ability to access, absorb and effectively take advantage of information and information technology. According to this document, the top 20 include the United States, Sweden, Australia, Canada, New Zealand, the United Kingdom, Denmark, Finland, Germany, Singapore, Japan and France. South Korea ranks 22 and China and India between 45 and 50.

Of course there are some encouraging signs. For example, doctors in 23 African countries use the Internet to obtain assistance in diagnosing and treating patients by applying directly to colleagues at some of the best medical centres in the world for advice. There are computer programmers in India working for large United States corporations, writing programs and sending their work via the Internet. Yet in many parts of the developing countries, the Internet – for those who have even heard of it – is still largely inaccessible. In the case of microelectronics and information technology, few noteworthy initiatives have been launched by research laboratories in OECD countries towards developing applications that would benefit developing countries – with perhaps one outstanding exception: in 1997 it was announced that four of the world's largest radio manufacturers would begin mass-producing a revolutionary new radio. This will be a hand-held portable radio capable of receiving hundreds of high-quality digital radio channels, text and even photographs broadcast by satellite. The specially designed radios are the chief element in an ambitious plan developed by Ethiopian-American Noah Samara to launch digital satellite radio services aimed at more than 4.6 billion people in the developing world. The first satellite, AfriStar, constructed by Alcatel of France,

was launched in the middle of 1998, followed by AsiaStar in 2000.

The future turned a little brighter in February 1997, when 68 members of the WTO agreed to lower telecommunications barriers. By opening these traditional state preserves to international competition, the agreement will radically restructure the global market. The developed countries will naturally get the lion's share of that market, but the agreement's benefits for the people of all countries are clear. Although many developing countries felt left out of the deliberations, they appeared to agree that a step forward had been achieved, if not the leap they had hoped for. It is estimated that if the new agreement promotes genuine competition, the cost of an international phone call could be cut by almost 80 per cent. Over the following decade, total savings to consumers are estimated at about US$1 trillion. All this could mean a telephone in every village, which for many could be a matter of life and death.

In March 1997, an agreement was reached to eliminate tariffs on some 200 information technology articles such as computers, chips, chip-making equipment, software and telecommunications equipment by January 2000. Developing countries have increasingly realized that they have more to lose than to gain by keeping their markets closed. Traditionally, these countries have been concerned about the threat to their own national operators from the large international carriers. They are aware, however, that they need US$60 billion annually simply to maintain their existing telecommunications services – and much more if they are to catch up with the more advanced countries. Foreign investment is the only way they can hope to find the capital. For the poorest countries, the two above-mentioned agreements offer an opportunity to use the 'latecomer's advantage', catching up with the rest of world by accelerating their development through more rapid and less costly implementation of new technologies such as cellular networks.

### Genetic engineering

It is clear that scientific research and technological innovation are essential for sustaining and accelerating development in Third World countries, but at present the countries' capacities for absorbing and applying modern science and technology are often very limited and require strengthening. While research and development (R&D) capacity in most developing countries is still underdeveloped and underfunded, OECD countries devote only a small fraction of their R&D efforts to problems that are specific to the Third World. Areas of R&D in which improved international cooperation would be desirable include biological research and biotechnology. More R&D should be directed towards improving production levels of crops in the Third World. A recent step in this direction was the establishment of the United Nations International Centre for Genetic Engineering and Biotechnology. The work of the Centre – carried out at its branches in Trieste, Italy, and in New Delhi, India – together with that of the CGIAR research network (Consultative Group on International Agricultural Research) will benefit agriculture and health in developing countries.

Biotechnology in OECD countries has experienced 'explosive growth' over recent years. By the end of 1996,

Europe alone had 716 entrepreneurial biotech companies, employing 27,500 people. Research in biotechnology has already produced some outstanding successes: discovering a way to modify a cell's identity by reprogramming its genes is an achievement with tremendous scientific and medical implications. Just recently, scientists genetically engineered bacteria that may one day prevent kissing bugs from spreading Chagas disease, which has infected about 18 million people in Latin America and kills 45,000 annually. The importance of biotechnology for solving food problems cannot be overestimated. Today in OECD countries, a burgeoning industry produces a variety of genetically modified food. There are grounds for hoping that in some not-so-distant future genetic engineering will allow developing countries to breed super-productive livestock – cows that can produce five or ten times the normal amount of milk, or larger chickens, pigs or fish – and plants that grow faster or are especially hardy or disease-resistant.

Scientists also hope to breed animals with special characteristics, such as organs that will not be rejected by immune systems when transplanted into humans. The successful animal-cloning experiment carried out in 1996 ('Dolly' the sheep) (Plate 50) constitutes another milestone in science, but it also reminds us once again that our reach continues to exceed our grasp. The ultimate effect on humanity of endless technological innovation has not yet been fully understood. Having succeeded in artificially producing materials that do not exist in the natural world, the human species is on the verge of entering a yet-unknown realm: the creation of new life forms. In many OECD countries today, there is consumer concern over possible side effects (nutritional, toxic or allergenic) of artificially introducing genes in food products. But these concerns, while perfectly legitimate, appear less critical when compared with the immense ethical and moral issues raised by the prospect of human cloning.

# 7.2
## AFRICA AND THE NEW INTERNATIONAL ECONOMIC ORDER

*Edmond Kwam Kouassi*

'One of the most complex problems facing humanity today is that of development, defined as a process involving the dynamic and cumulative liberation as well as transformation of the mental, political, economic, cultural and social structures of any human group according to their particular values and pace.'[1]

Thus, the political and economic aspects of the relations between rich and poor countries have, for a long time, remained at the core of international debates. During the colonial period, the relations between the colonizing 'North' and the territories of the 'South' were often of the sovereign-to-subjects, 'horseman and horse', 'fox in the henhouse' variety. However, since gaining political independence, the countries of the South fostered more complex and ambiguous relations with the countries of the North. With the advent of a new era – namely that of bargaining and negotiation – one could no longer speak of the balance of 'forces' of 'subjection.' In most cases, the respective negotiation positions of the North and the South are fundamentally asymmetrical given that, in general, the states of the North are significantly more powerful than their partners of the South. Generally, the North-South bargain concurrently involves a number of problems that not only complicate the negotiations but also provide them with greater substance.

During the 1950s and 1960s, most North-South meetings had taken place under the aegis of the political independence of the former colonized countries since the focus was put on the standard issues of 'security' and economic assistance. By the end of the 1960s, many realized that political independence only existed in the legal sense and that it had also failed to culminate in the economic growth and development expected by the leaders of liberation movements. It is for this reason that, towards the late 1960s and early 1970s, attention was focused on economic issues such as improved terms of trade, market access, lending conditions and monetary relations. These issues concerned all the countries of the South and particularly Africa, which, working through the Non-Aligned Movement, made a significant contribution towards urging the international community to address them.

The most striking development of this era was undoubtedly the United Nations Extraordinary Session on raw materials and development, which took place in 1974. Although the session did not pave the way for any general agreement between the industrial and developing countries, three important texts were adopted by consensus (i.e., without formal voting since consensus was defined at the Helsinki Conference on Security, Stability and Cooperation in Europe as 'the absence of an objection raised by a delegation, which can stall decision-making'): a declaration concerning the establishment of a new international economic order; a 'programme of action' to operationalize the principles of the declaration; and a special assistance programme to Third World countries facing severe economic crisis and natural disasters.[2] However, serious reservations expressed by the industrialized countries on a number of provisions in these texts, coupled with the attempt by the Group of 77, a coalition of over 100 countries, to have its proposed assistance programme adopted instead of the American proposal, showed that the ideological, economic and political gap between the rich and the poor countries had not yet been bridged.

Nonetheless, the session marked a serious turning point in international relations. In the context of the energy crisis, it conferred credibility to the political force and economic power of the developing countries. For the first time in the history of the United Nations, the General Assembly worked on the basis of documents prepared by Third World countries. The development problem, taken as a whole, and not solely the processing of raw materials, was highlighted at the highest international level by the concerned parties themselves. Considered one of the world's priorities by all the nations of the world for some twenty-five years, the development problem has in fact been exacerbated. The failure of the international development strategy has been acknowledged by all.

Algerian President Boumediene highlighted the problem with greater pertinence in his address to the General Assembly: 'The commodities markets – coupled with the virtual monopoly of manufactured and capital goods, and the monopoly over capital and services – enabled the developed countries to fix, in their own way, both the prices

of raw materials, which they procure from the developing countries, and the prices of the goods and services they deliver to the developing countries. Thus, they are in a position of obtaining for their own advantage the resources of the Third World countries through a multitude of channels'.[3] Indeed, according to the United Nations Conference on Trade and Development (UNCTAD), the market economy industrialized countries, which are four times less populated than the poor countries, consume nine-tenths of the total non-ferrous metals supplied, four-fifths of the world's oil and natural rubber production and half of all unprocessed cotton, vegetable oils and sugar. This consumption, which is sometimes wasteful, was spurred by the relatively low prices of these agricultural commodities.

This situation has persisted to the present day because the Third World does not have the necessary leverage in international affairs. The increased number of independent states, instead of leading to an equitable and commensurate involvement in the responsibilities of managing world affairs, has resulted in a greater concentration of decision-making powers in the hands of a closed circle of privileged powers, which wield virtually discretionary powers in handling major problems. The same applies to the international finance structures. In concrete terms, the issues at stake are a more equitable distribution of the fruits of economic growth, the bridging of the income gap, greater participation in responsibilities and dignity.

The proposed New International Economic Order thus aims at establishing a new system calling for not only 'the abolition of privileges' of the industrialized countries, but also an economic constitution that will guarantee the rights of the peoples of the Third World to establish a new type of international economic relations based on mutual benefit, complementarity and common development.

The demands of the developing world are intended to bring about a solidarity-driven, international-based, more harmonious community where the inhabitant of the Third World – the person wrongly seen by Professor Gonidec as having 'the eyes of a child and bare hands' – ceases to be the prey of the strong and the rich. The developing world looks forward to a responsible and balanced community in which it ceases to be the 'the child who lies prostrate beyond the light of History' as was wrongly claimed by Hegel in his ideas about the African continent.

Through a number of resolutions, declarations and action programmes, Third World countries have formulated strategies, development decades and model societies backed by a coherent ideology, thereby giving some meaning to the New International Economic Order. The central thrust of the New International Economic Order is to review existing structures in the fields of international economic relations to enable Third World countries to begin or accelerate an internal and relatively autonomous process of growth, diversification and integration. This process must be conducted in such a way as to ensure that Third World countries are in a position to deal efficiently with the looming internal crises affecting them today, namely, mass poverty, widespread unemployment and the glaring food deficit. The focus was placed on the means of providing the developing countries with increased net resource flows primarily through trade and assistance.

Other important issues involve the raw materials problem, the reform of the international monetary system and funding development in poor countries, industrialization,

technology transfer, the regulation and control of transnational corporations, and promoting cooperation among the developing countries

Since the main thrust of these texts concerns the redistribution of economic power on the world scale rather than the transfer of resources emanating from international assistance, the developing countries have set three objectives:

1. the effective control of wealth, natural resources and economic activity;
2. commercializing resources and activities at stable, equitable and remunerative prices;
3. establishing a common front for international negotiations.

Relying on the experience of OPEC (Organization of the Petroleum Exporting Countries) and working within the structures of the United Nations in which they would be assured a majority, they aimed to enable developing countries to exert a three-fold control over their products: control of ownership, control of the market, control of the group's solidarity by maintaining a common front. It is for this reason that Mario Bettati affirmed that the Third World's demands for a New Economic Order were formulated to achieve the following three objectives:

1. consolidating the economic sovereignty of developing countries;
2. searching for institutional changes in trade;
3. promoting endogenous development.

Africa has contributed extensively to the conception of such a programme. Nonetheless, its success depended on the reality and the consistency of the political will of the protagonists, and the cohesion of the entire group of developing countries.

## ORIGIN OF THE EXISTING INTERNATIONAL ECONOMIC ORDER

In describing the current world economic situation, strictly speaking it is inappropriate to refer to an international economic 'order' as what is referred to is more precisely an 'interaction' at the global level, which is the result of economic forces (and the actions of national powers) and of a particular historical situation.

During the nineteenth century and the first half of the twentieth century, a large number of countries now called 'developing' were in fact territories dependent on European powers. The latter determined the destiny of their territories and dictated the types of economic policy they should pursue and their role in international economic relations. During this period, those who lived under the tutelage of colonial powers did not enjoy full political and economic freedom. They had no control over their natural resources and did not receive equitable payment for their produce. This mode of economic and trade relations benefited only the colonial powers, and the dominated territories were given the minimum necessary to ensure the functioning of an administration compelled to impose the type of public order deemed suitable by the European countries.

The current economic order was therefore instituted at a time when the vast majority of developing countries were dependent territories. This economic order, which did not involve the active participation of these countries, is very unfavourable to them. It is generally accepted that economic

and monetary relations are based on three principles: freedom, equality and reciprocity. However, these principles cannot ensure general prosperity unless all the countries have equal resources. In the present world, where powerful states border poor and weak ones, they can only work to the advantage of the strong and to the detriment of the weak. Indeed, freedom favours exploitation, legal equality generates material inequality and reciprocity in concessions deepens the already wide gap between rich and poor countries.

One should therefore see in the existing order a veritable 'disorder'; one can refer to a new order only if any order had indeed ever existed, and this is not the case. The current order is a great obstacle to the enjoyment of the human rights and fundamental freedoms proclaimed in the Universal Declaration of Human Rights, particularly Article 25, according to which 'Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family'. The international economic order is unjust mainly because the developing countries were not involved in its establishment and must nevertheless endure all the consequences. It is therefore necessary to change the situation in the interest of the international community as a whole. The call for this change was inspired by a number of political and legal texts, which are analysed in the following section.

## ARGUMENTS FOR A NEW INTERNATIONAL ECONOMIC ORDER

In the quest for a new international economic order, there are two categories of arguments, namely, political and legal.

### The political argument and the declaration for the establishment of a new international economic order

In order to break out of the crisis besetting the international economy since 1973, it was necessary to embark on action at the international level. The opportunity was provided by the initiative of OPEC, which decided to increase oil prices on 16 October 1973.

On 31 January 1974, Boumediene, in his capacity as chairperson of the Non-Aligned Movement, requested that an Extraordinary United Nations General Assembly be convened to consider the issue of raw materials of the poor countries. Following the acceptance of this proposal, the United Nations General Assembly met from 9 April to 2 May in New York in an extraordinary session and adopted Resolution 3201 'Declaration concerning the establishment of a New International Economic Order' (NIEO). This declaration stated inter alia: 'We, the Members of the United Nations... Solemnly proclaim our united determination to work urgently for the establishment of a New International Economic Order based on equity, sovereign equality, interdependence, common interest and cooperation among all States, irrespective of their economic and social systems, which shall correct inequalities and redress existing injustices, make it possible to eliminate the widening gap between the developed and developing countries and ensure steadily accelerating economic and social development and peace and justice for present and future generations.'

The declaration condemns the current situation and sets out the principles that should govern the New International Economic Order. The highlights of this document, as set forth in the introductory paragraphs, are as follows:

- Point 5 presents the principle of full sovereignty of states over their natural resources and economic activities, the right to exercise effective control over them and their exploitation with means appropriate to their own situation including the right to nationalize or transfer ownership to its nationals. This article also stipulates that no state may be subject to any economic, political or any other type of coercion aimed at hampering the free and complete exercise of this inalienable right.
- Point 6 states that all states, territories and peoples under alien and colonial domination or apartheid shall be entitled to restitution and total compensation for the exploitation, reduction and degradation of the natural resources and any other resources of those states, territories and peoples.
- Point 10 calls for a just and fair relationship between the prices of raw materials, primary commodities, manufactured and semi-manufactured goods exported by developing countries and the prices of raw materials, primary commodities, manufactured goods, capital goods and equipment imported by developing countries with the aim of fostering sustained improvement in the terms of trade as well as the broadening of world economic cooperation.
- Point 17 states the need to put an end to the waste of natural resources including food products.
- Encouraging the creation of OPEC-model cartels, Point 20 recommends facilitating the role played by producers' associations in international cooperation, and, with a view to attaining their objectives inter alia, contributing towards the sustained growth of the international economy and accelerating the development of developing countries.

It is obvious that the operationalization of this declaration requires a legal basis.

### The legal basis of a new international economic order

Pursuant to the operationalization of the principles of the NIEO declaration, the General Assembly also adopted a programme of action. This notwithstanding, a Charter of the Economic Rights and Duties of States was adopted a few months later.

### Programme of action

The programme of action outlines measures aimed at ensuring balance in the commodities market, the international monetary system and funding of economic development. It also spells out the measures to promote industrialization, technology exchange procedures and the monitoring of the activities of transnational corporations.

The programme provides for support to cooperation among developing countries, assistance to states in ensuring their permanent sovereignty over their natural resources, the strengthening of the role of the United Nations in the field of international economic relations and the special

emergency measures in favour of the developing countries most severely affected by the economic crisis. Resolution 3202 added that 'the relevant subsidiary United Nations organisations, institutions and agencies shall all submit to the Economic and Social Council, as often as may be necessary, but at least once in a year, interim reports on the implementation of this Programme of Action in their respective fields of competence.'

The programme of action also calls for the adoption of a Charter of the Economic Rights and Duties of States

## The Charter of Economic Rights and Duties of States

The Charter of the Economic Rights and Duties of States was adopted by the 29th session of the United Nations General Assembly in December 1974. Enshrined in Resolution 3281, this charter spells out the principles that should govern the economic relations between states. In its preliminary articles, the charter deals with the sovereign and inalienable right of each state to chose its economic system in the same manner as its political, social and cultural systems in accordance with the will of its people, without any interference, pressure or external threat whatsoever. The charter also outlines the principle of the right of each state to regulate and supervise the activities of transnational corporations. It further underscores the right of all states to participate fully and effectively in the adoption, at the international level, of the decisions aimed at resolving global economic, financial and monetary problems and to access equitably the benefits accruing therefrom. It also emphasizes the duty of all states to cooperate individually and collectively in order to remove obstacles impeding the mobilization and full utilization of their resources for the promotion of the economic, social and cultural progress of their people.

The legal basis of the New International Economic Order raises the problem of the legality of the norms outlined by the United Nations General Assembly. While it is generally agreed that the legal basis of a norm is dependent on the competence of the organ that conceives it, the following questions arise: Are norms such as the Programme of Action and the Charter on the Economic Rights and Duties of States declaratory norms of an existing law or constituent norms of a new law in gestation? And do they have a compelling force? Such a problem, in the final analysis, boils down to the competence of the General Assembly. The issue is complex and controversial.

Advocates of a restrictive interpretation of the competence of the General Assembly challenge the validity and compelling character of the General Assembly resolutions. In fact, the latter contend that the source of international law is solely rooted in the practice of states, international treaties and judicial decisions. Objectively, the General Assembly resolutions do not fall under any of these categories. They further argue that under Articles 10 through 14 of the United Nations Charter, the General Assembly has limited competence, namely, that of making discussions and submitting recommendations but not to legislate for the international community. This was particularly argued by Professor Georges Fisher in an article entitled: 'The Sovereignty of States over their Natural Resources.'[4]

On the other hand, advocates of liberal integration affirm the competence the General Assembly and the binding nature of its resolutions. One of the major representatives of this opinion, Judge Lautherpact, argued that it could be inconsistent with the principles of sound interpretation to downplay the values of General Assembly resolutions, one of the main instruments for expressing the collective will and judgment of the community of nations, and to consider them theoretic, insignificant and incapable of exerting influence on the conduct of Member States.[5]

Based on this second opinion, all the norms outlined by the General Assembly for the creation of the New International Economic Order or the development of the states must be considered as legal rules within the branch of public international law known as international development law. However, this is obviously not the position of the countries of the North, which, in their relations with Africa and the Third World, hardly ceased to trample on these regulations.

## THE RESURGENCE OF THE OLD ORDER

Africa's debt accounted for 50 per cent of GNP in 1983 and its annual debt-servicing currently represents 45 per cent of export earnings. This tremendous debt burden eventually overshadowed the signs of recovery observed in the economies of many African countries in the mid-1970s. The structural adjustment programmes initiated by the World Bank and the International Monetary Fund, which have encumbered debt overhang, bear witness to an ailing economy, to the extent that the social costs of these reforms have seriously compromised the states' development efforts in priority sectors such as education or health, which have been neglected by national budgets.

If the New International Economic Order was aimed at establishing a new type of international economic relations, it was an undeniable failure, and this process seems to have been permanently compromised. Since the end of the nineteenth century 'we have witnessed the epiphany of an economic liberalism' relayed by the World Bank and the IMF, which pressured African states into accepting the conditionality resulting from globalization, 'thus succumbing haplessly to the will of these institutions, abdicating all sovereignty, forsaking any effort to design for themselves … their development project.'[6]

In fact, 'globalization has undermined the sovereignty of states'[7] in an unprecedented manner. 'The money markets reign supreme … with rules which only they themselves are masters of and can hence dictate their laws to states'.[8] Even if we consider these reforms simply in terms of sound management and efficiency, crucial questions arise: Which development project should be implemented? Who defines the development project? If care is not taken in the future, the principal role of the state will be limited to creating the conditions suitable for the effective functioning of market forces. In the meantime, the development of Africa cannot accommodate the creation of an additional or residual state.[9]

Even the sovereignty of states was undermined cunningly when American law sought to extend beyond its borders.[10] Two clear examples of this are the Helms-Burton Act and the Amato-Kennedy Act of 1996. The former bans imports or exports and the financing of goods and services originating from Cuba. It also provides for the suspension of financial assistance to states or international organizations extending

assistance to Cuba. The Amato-Kennedy Act imposes severe sanctions on any company investing over US$40 million in the oil and gas sectors in Iran and Libya. The United States therefore passes legislation to penalize non-American nationals for their activities outside American territory, thereby ignoring the most elementary rules of international law in the field of territoriality, responsibility, non-retroactivity and the rights of the peoples to their national wealth and resources. The denunciation of this claim to extraterritoriality of American law by the United Nations General Assembly (the resolution passed on 2 November 1995 and the complaint submitted to the World Trade Organization by the European Union in 1996) were to no avail, which is an eloquent testimony of the effectiveness of the WTO.

## INTO THE TWENTY-FIRST CENTURY

The call for a New Economic Order, expressed in a particularly clear, firm and responsible manner, was based on simple principles such as bridging the enormous gap between the countries of the North and the South by the elimination of inequalities and injustices.

After over three decades of struggle for the creation of a new, solidarity-based and equitable order, the efforts have resulted in failure, since none of the proclaimed principles has been applied. It has also been a failure both for Africa and the rest of the Group of 77, as evidenced by the worsening terms of trade, the persistent collapse in commodity prices, the disappointing results of the Cancun Summit in 2003 on the issue of 'equitable cotton', capital flight, the relatively weak industrial activity in the states of the South, which confirms the reluctance of the industrialized countries to effectively transfer technology.

Proposed alternative solutions have taken the form of bilateral cooperation agreements, which unfortunately fail to provide the same promises, benefits and prospects as those contained in the Programme of the New International Economic Order because such cooperation is often motivated by strategic interests rather than by the concern for the establishment of a solidarity-based, harmonious, equitable and responsible development.

For its part, Africa began the twenty-first century by adopting initiatives crucial to the continent's progress: the Organization of African Unity has paved the way for the African Union, whose constituent act was signed in Lomé on 11 July 2000. Consequently Africa now has a continental organization organically diversified and with a more markedly 'integrationist' agenda. Launched in 2000, the New Partnership for Africa's Development (NEPAD), which reflects the will of Africans to assume responsibility for their destiny, aims to prevent Africa from depending exclusively on international assistance and to make it attractive to investors. These advances have contrasted paradoxically with the perceptible mark of regression in the ideological and legal substrates from which the New International Economic Order has drawn for its promotion.

The departure of the countries of Central and Eastern Europe from the Soviet Union's orbit that began in 1990 marked not only the end of the Cold War and the triumph of the market economy, but also the questioning of alternatives that have been tried without any tangible results.

Resolution A45/1999 of 21 December 1990, concerning the fourth United Nations Development Decade, marked a decisive political turning point in that it abandoned the terminology of the New International Economic Order. The decline of the New International Economic Order as advocated in the historic resolutions of 1974 has been accompanied by the ascendancy of globalization, whose institutional expression is illustrated by the creation of the WTO on 10 January 1995. Unlike the New International Economic Order, globalization presents an alternative because it does not require any reform other than that of trade liberalization. It is based on the model successfully showcased by the Western world, and, more precisely, the United States.

In the spirit of the New International Economic Order, the analysis of the equality of states, for instance, was not limited to the call for the curtailment of the inequality of power but incorporated the equality of development and justified the acknowledgement of a specific category of developing countries. This analysis is no longer consistent with the fundamental laws of a worldwide market, based on a strict compliance with competition, which implies the relinquishment of discriminatory rules, preferential regimes, and double standards.

Undoubtedly, the WTO does not ignore developing countries. From this viewpoint, it entails neither a rupture nor major innovation as regards the North-South gap. The spirit of the constituent text is different, however, owing to the liberal context, and if the developing countries can hope to receive special treatment, such a status no longer appears as a temporary favour justified by the objective of rapid market access.

Should one also cancel what has been previously achieved under the influence of the New International Economic Order? Not at all. Most of the texts are mere recommendations, and it will suffice to forget them. With regard to the rules of positive law establishing preferences, there is little doubt that these will systematically become irrelevant. One could simply conclude that it is necessary to revert to the neutrality of positivism. One can legitimately wonder, however, whether this reversion to 'political realism' and to 'a greater normative orthodoxy' is not due to the will of the most powerful to accede to new markets rather than to the demands of formalism and to any legal neutrality.

What remains certain, however, is that the search for a New International Economic Order can be seen as an outdated issue as far as its initial interventionist and conflict-prone orientation is concerned; yet it remains an indispensable historical necessity regardless of the form it may eventually take.

# CONCLUSION

*Iba Der Thiam*

After years of war and international tension, as well as economic, scientific and technological progress, the world has undergone unprecedented upheaval during the twentieth century.

New hopes have arisen since 1994: with the wave of independence in the 1960s, the fall of the Berlin Wall, the disappearance of the world communist movement, the end of the Cold War and the arms race, the world is now evolving towards a new era of peace, even though domestic crises of an ethnic, tribal or religious nature still threaten certain countries. Colonialism has been defeated, apartheid put down, the balance of terror abolished. We are witnessing the genisis of a new international order founded on the promotion of human rights, democracy, a free press, market economies, the protection of women's, children's and minorities' rights and the right to a better quality of life through respect for the environment. This new international order must help to bring about certain changes needed in the international relationships established in the wake of the Second World War and to create mutually advantageous and more equitable economic and commercial relations between North and South. It must also facilitate the opening of Western markets to the products of the developing countries, and the reduction of the ever-increasing inequalities in science and technology, communications, computer use and culture.

Indeed, the United Nations and the FAO are now headed by Africans, growth has returned with the improvement in the main macro-economic indicators, and an African contributed to the success of the American mission to Mars. Clearly, these fine accomplishments, along with the edifying signals of progress in the struggle against corruption and conflict (both internal and external) must be recognized. Yet, we must also acknowledge that a great deal still remains to be done in developing countries. Day by day, poverty's grip grows a little tighter, while unemployment, underemployment and malnutrition are on the rise. Diseases, such as tuberculosis, that were once in decline are returning with a vengeance, and AIDS continues to be a major worry. Illiteracy is still widespread. Investment, though considerable, is still desperately inadequate in certain developing countries, especially in Africa, and debt, which remains a heavy burden on their economies, is constantly sapping their capacity for growth. Peace – the missing link between development and democracy – is still unknown to many regions, and this compromises the prospects for ecologically viable and sustainable development. The sense of solidarity embracing all of humanity is on the ebb as evidenced by the disturbing drop in development aid. The growing support of right-wing movements in the West is accentuating fears of exclusion, selfishness and covert racism, and the conditions for a new and better-balanced partnership between rich countries and poor still appear far off.

There are therefore many challenges still to be met, the greatest being the free circulation of knowledge and people (the essential counterpart to that of capital, goods and services, and ideas), the democratization of international relations and the setting of fair prices for raw materials supplied by developing countries. In the new century, peace and the future of the planet will depend on the resolution of these crucial issues.

# WOMEN

## Françoise Thébaud

The first edition of the *History of Humanity* was published under the auspices of UNESCO in 1965. Since then, the world and our knowledge of it have changed considerably. This is especially true of the status and social position of women, who, at the beginning of the twenty-first century, number three billion individuals and constitute roughly half of the human race. This is even truer in regard to sociological, anthropological and historical studies of women and relations between the sexes (now commonly known as genders). Prior to the end of the 1960s, these studies were few and far between, or limited to static and picturesque descriptions of an immutable feminine status. They developed on the initiative of feminist movements and have grown in number over the last three decades, initially in North America and Europe, then on other continents, especially in fledgling democracies (for example, in Latin America), where they are regarded as a factor of democratization and social progress. In denouncing discourses centred on myth or tradition, in criticizing the blindness of the social sciences to the presence of women and to differences between the sexes, they made gender an essential category of analysis, alongside other more established categories such as national, ethnic or social affiliation. Today, at any level, it is difficult to refer to human beings neutrally. Differences between men and women now rank highly among the differences which have been perceived, or exposed. Following a long lack of interest on the part of the community of historians, women's history and gender issues have featured prominently at the last three International Congresses of Historical Science (Madrid 1990, Montreal 1995, Oslo 2000).[1]

Although the developments outlined above explain the need for this chapter on women, it is neither straightforward nor simple to write. As part of this extensive publication chiefly concerned with the scientific and cultural development of humanity, the present study must first of all take into consideration the philosophy and structure of the whole. As with the issues relating to young, elderly or handicapped people, those concerning woman cut across the entire range of approaches, whether chronological, thematic or regional. This chapter – a potentially inexhaustible thematic summary – will need to consider

both the chronology and the variety of situations existing in the different continental, national, or regional contexts. Written by a French woman, it must as far as possible avoid giving a Eurocentric perspective and should not give priority to Western examples. Rather, it should place equal emphasis on points of international convergence, and on national and group identities. In line with the rest of the collection, it will focus on structures rather than events. However, the latter cannot be omitted from a historical analysis of the twentieth century, a century marked by numerous wars, dictatorships, revolutions, scientific discoveries, and technological transformations. Although there is such a thing as a biological female sex, there is no condition of women existing outside time and space. As research on women has emphasized, at times so trenchantly as to appear provocative, 'Woman' does not exist.

A brief presentation of the debates that have recurred in women's studies, and especially in women's history, over the last 30 years is a useful preliminary to any attempt at providing an overview and choosing an outline to follow. In its early days, women's history developed by declaring that the condition of women is not the product of a female nature that supposedly induces an intangible status and roles that are repeated from one generation to the next, but is the product of a historically determined social and cultural construct. It preferred the concept of the position of women in society, and later, of sex- or gender-related social relations, to the over-essentialist concept of the condition of women, and at times, particularly in African history,[2] it has defined itself in opposition to anthropology, seen as a 'colonial science' describing societies called 'traditional' or 'immobile'. Today, in Europe at least, the relationship between the two disciplines is less conflictual. However, although a study of the construct and various meanings of femininity may be justified, the approach developed here will be primarily historical, favouring processes and evolutions.

Evolution does not denote linear progress achieved by the tireless campaigning of women activists. Without denying that, for millions of women, improvement can be measured by the acquisition of new rights or better living conditions, today women's history is conscious of backsliding and the displacement and reconstitution of inequalities. For

this reason, it is no simple task to suggest a chronology of the twentieth century based on women and gender. In Europe and North America,[3] the 1960s and 1970s – marked by peace and prosperity, by technological innovations such as the invention of the contraceptive pill, by the growing participation of women in the labour force, by the rise of more and more anti-establishment movements and the emergence of a new kind of feminism – heralded the start of a fundamental shift in relations between men and women. This shift advanced the individual rights of women, and gradually granted them economic, legal and symbolic autonomy in relation to their fathers and husbands. However, what is the situation like on other continents, where family pressures, poverty and often war, all have an impact upon women? According to the context under consideration, the answer often varies with each continent, country and village, where the construction of a well or a school may transform daily life. Most international reports highlight improvement in the situation of women from the 1970s onwards as well as its deterioration in places during the 1990s, due to the world crisis, the development of liberalism and economic globalization, the rise of fundamentalism, the ravages of AIDS, or the increase in local conflicts. This deterioration led to the United Nations decision to hold an additional World Conference on Women (Beijing, 1995) as a follow-up to the three that took place during the 'Decade for Women' (1975–85).

The concept of progress also presupposes agreement about a particular development model. Today, Western feminists – separated into an egalitarian branch, and a differentiating branch based on according greater value to what is feminine – recognize that difference is not the opposite of equality (but of similitude) and that the two concepts can coexist. In the 1980s, national minority women activists and Third-World feminists criticized the imperialism of the Western model (that of a wealthy white woman), in the name of different cultural traditions and other social and political realities. As emphasized by the title of an American book published in the 1990s, on the history of women in the United States,[4] this legitimate criticism led to greater awareness-raising of inequalities between women in the same country and in the world, and reoriented women's studies towards an approach more inclusive of difference. However, recognition of diversity should not disguise the existence of laws, which can be liberating or oppressive for women, of situations of autonomy or minority status, or of significant indicators of their condition (for example, the literacy rate or the rate of mortality in childbirth). Liberty, dignity, and equality are universal values, endorsed by the international community, but challenged by the world's most conservative states. During the most recent international conferences (on population in Cairo, 1994, or in Beijing), these states attempted to counter such values with the concepts of complementarity of the sexes, or equity.

'Unequal sisters': the world of women is made up of common ground (motherhood, ensuring the cohesion and care of the family, vulnerability to violence), of solidarities which may be partial and temporary, and of differences which, on a world scale, are often greater than the level of sexual inequality measured in each country. Being the result of inequalities between societies, inequalities between women from one place to another (a state can be 'ahead' in one aspect and 'behind' in another) may be accentuated by issues relating to social affiliation, race, age or religion, and by the persistence of ancient hierarchies between peoples (Africa, former white colonies), or of castes (India). Without a map to show the situation today (see *The State of Women in the World Atlas* by the Canadian Joni Seager in the bibliography), this global panorama must avoid any generalization or at least, where information is available and relevant work has been produced in the field of women's history, any generalization must be qualified by contrasting examples. Despite the litany of women's woes over the last century and in the world today, our overview must ultimately present women, not solely as victims of the established order, but also as people directly involved with their own lives and histories, not just well-known personalities, but anonymous women too. This is the latest lesson to emerge from recent debates and from development policies.

These preliminaries, to be borne in mind when reading the pages that follow, lead me to the following choice: after focusing on the constant burden of war, and in counterpoint, the gradual affirmation of women's rights, the chapter will tackle the themes of the family, motherhood, work, and access to knowledge and power, from a combined chronological and geographical point of view.

## THE CONSTANT BURDEN OF WAR

The twentieth century was one of the bloodiest in the history of humanity. War in all its forms was omnipresent throughout: two world wars, colonial and post-colonial wars, wars of national liberation, not to mention the civil wars that destroyed the fabric of many societies. The issue of the relationship between war and social change, and in particular of its impact on gender and the status of women, has often been raised by both contemporary commentators and historians. Does war lead to the emancipation of women? Before considering the involvement of women in conflict and giving a qualified response to this question, it should be emphasized that war is synonymous with violence, and that first and foremost, women are its victims.

Nine million military personnel were killed between 1914 and 1919. There were 50 million deaths between 1939 and 1945, of which 20 million were Soviet and half of those were Soviet civilians, and there have been millions more since. War claims the lives of men (husbands, sons, brothers), who may never come home, or who return injured and traumatized. Universally present – although experienced in various ways according to place and culture – solitude, distress and mourning are the lot of women. Women have sometimes organized peace movements in the name of life and motherhood, only to then be denounced as traitors to their communities (most recently to date, the 'Women in Black' of Israel or Serbia). War, and its accompanying loss of income and pillage of industrial or agricultural wealth, also exacerbates the difficulties in material living conditions and weighs particularly heavily on women, who are responsible for feeding their families. In Europe, drastic shortages were prevalent only in parts of Central Europe during the First World War, but 25 years later, the whole of German-occupied Europe was affected. People were forced to return to a way of life associated with a subsistence economy, and the shortages ultimately led to hunger riots. Elsewhere, in rural economies, the destruction of crops by armies or bombardment could be catastrophic.

The exacerbation of poverty beyond endurable limits, or the lack of separation between the front and rear lines, increasingly common in contemporary warfare, frequently led to the exodus of women, children and the elderly, struggling to escape conflict and famine. In the world today, over 80 per cent of refugees are women and children, fleeing countries such as Afghanistan, Rwanda, Sudan and Serbia.

Increasingly, war has a direct physical impact on women, and the 'rules of war' have tried in vain to make their bodies sacrosanct. Although, the majority of totalitarian regimes enforced the appalling concept of family guilt, the Nazis' policy of extermination of Jews and Gypsies, and the barbarities that took place in the occupied territories (in particular against the Slavs and the resistance), pushed back the boundaries of abomination. The names of the death camps (such as Auschwitz, Sobibor and Belzec) and of the civilian massacres (such as Guernica in Spain, Baby Yar in the USSR, Oradour-sur-Glane in France) will remain indelibly printed on the collective memory. Perpetrators of genocide (the term is also used in reference to the Khmer Rouge in Cambodia, to Rwanda and former Yugoslavia) show no particular pity for the female sex, but quite the opposite since women are mothers or potential mothers of future generations. In all wars, women, seen as part of the spoils and as the 'warrior's well-earned rest', have been raped (at Nanjing sacked by the Japanese in 1937; in Spain during the Civil War from 1936 to 1939; in Germany during liberation by Russian soldiers, 1945; in Bangladesh in 1971; and elsewhere). Others, seen as traitors to their nation, had their heads shaved.[5] But the systematic practice of rape (notably perpetrated by the Serbs against Bosnian Muslim women),[6] recently made it a weapon of war and 'ethnic cleansing', recognized as a war crime thanks to campaigning by international women's networks, and punishable by the International Criminal Tribunals of The Hague, established in 1993. Although a certain proportion of men are brutally tortured and massacred in war, rape has the specific aim of humiliating the enemy and publicly desecrating the values it holds sacred to conquer 'ethnically' (via an interposed womb representing the homeland, or mother earth) and to destroy the blood ties of the other culture. As victims of this violation, defiled and dishonoured, raped women have often been rejected by their families.

Twentieth-century conflicts were wars of men and material. They required the support and assistance of women behind the lines, mobilized in the war effort to bolster the morale of troops and civilian populations, called upon (and often compelled by necessity) to replace men in fields, factories or offices to keep the country alive and the war machine moving. This led to a complete subversion of traditional gender roles. The number of women in employment increased (from 20 to 50 per cent among the belligerents in the First World War, and still further in the United States and United Kingdom between 1939 and 1945). Women broke into traditionally masculine trades (e.g., lathe operators producing shells or engine drivers), and, in increasingly varied roles, into the armed forces. The USSR recruited women combatants as early as 1943, including heroic fighter or bomber pilots. In this way, women in countries at war took on new social and family responsibilities, tested their abilities, demonstrated the full range of their skills, and conquered the public sphere previously occupied by men.

Women also took part in resistance against occupying forces and in wars of decolonization and national liberation. Among female members of resistance groups who earned a place in history this way are: in France, Berthie Albrecht (co-founder of the 'Combat' movement, executed by the Germans in 1943), or the communist Danielle Casanova, who died as a deportee; in Algeria, Hassiba ben Bouali (planter of bombs, killed in 1957 during the Battle of Algiers), or Djamila Boupacha, the FLN (Front de libération nationale) liaison officer whose arrest, torture and trial became an international affair in 1960. However, this phenomenon extended worldwide. While a minority joined the guerrillas, courageously transgressing behaviour codes, a greater number supported fighters behind the scenes (hiding, supplying, feeding, healing) or rebelled against the repercussions of occupation. The decades-long struggle by black South African women for freedom of movement (against apartheid and the carrying of passes) has similarities with the fight of West African women against the poll tax. This fight, conducted with daring to secure their economic survival, drew them into the political struggle despite and because of repression. Although they were subjugated to patriarchal authority, Kikuyu peasant women joined the Mau Mau rebellion in Kenya for similar reasons. The British, who termed their lengthy resistance 'passive', responded to it with a forced return to the villages and the establishment of women's progress clubs. However, they misunderstood the commitment of these women, 35,000 of whom were imprisoned between 1952 and 1958, and whose mental and social environment was profoundly changed as a result. Among those imprisoned was the rebellion's most famous nationalist woman activist, Rebecca Njeri.[7] In 1919, Chinese women played an active role in the 4 May Movement (against foreign imperialism and the Confucianism of the traditional elites) and raised the issue of women's rights; and many Indian women took part in Gandhi's Non-Violent Resistance and, in doing so, gained legal and political equality in independent India.

War, however, was rarely propitious to the evolution of gender relations, even though the awareness and individual behaviour of some women was changed by it and some ground was gained – for example, in many Western states, the right to vote, or the incorporation of the principle of equality in their constitutions. In such states, the mobilization of women was seen as an interim measure (Plate 51). Once the armistice was signed, they were requested to step down in favour of male ex-combatants and to repopulate the country. Decolonized states, wishing to assert their national identity, have often given women the role of guardians of traditional values or have emphasized priorities other than their emancipation. After 1962, Algerian women were obliged to conform to Arab-Muslim values, to stay at home and wear the veil, while today, Palestinian women activists find it difficult to marry after imprisonment, which stains the family honour. Despite the increasing volume of women's war literature, few women have been or are able to give collective meaning to their experiences and above all, to impose their view of things. Nationalism and women's rights have often been incompatible. The lesson to be learned from the twentieth century is that peace and democracy, open to the circulation of ideas and people and to the constitution of feminist and women's organizations, are more favourable to the promotion of women's rights than war.

## THE EMERGENCE AND AFFIRMATION OF WOMEN'S RIGHTS

Structuralist anthropologists[8] set as an invariant the existence of a 'differential valency of the sexes' characterized by the dominance of the masculine principle over the feminine principle and connoting the binary system of opposites that we use in order to think. According to them, on a historical and world scale, no societies, even those that are matrilineal, exist without masculine domination. This can be explained by the will of men to overturn the privilege of women and to appropriate their reproductive capacity to engender sons. The resilience and longevity of this system of representation – and only too often, of real violence – explains why the concept of sexual equality and of the autonomy and rights of women had difficulty emerging. In the West, this concept, which made fleeting appearances in various places and at various times, gradually asserted itself in the nineteenth century, stimulated by the challenges to other hierarchies and forms of oppression such as slavery, religious persecution, feudal relationships or class relations. The concepts of reason and progress derived from the philosophy of the Enlightenment, then the movement towards democracy, swelled an egalitarian movement calling for the equality of all individuals and extended the Declaration of the Rights of Man and the Citizen of 1789 to include women. Utopian socialism took this further, adding enhancement of the status of motherhood and belief in the moral superiority of women. Marxist socialism tended to subordinate the issue to the triumph of the revolution, prior to its manifestation (post-1917) in states where, despite the fact that the reality was more complicated, the issue of sexual inequality was considered as settled.

In the nineteenth century, religious dissidence, especially Protestant, was also a breeding ground for feminism (the term took on its current meaning at the end of that century), particularly in its dualist form, which demanded rights in the name of the difference between the sexes. In the longer term, it raised the inescapable issue of the sexism of the major religions, condemned by numerous contemporary feminists such as the Indian Chandra Rami Chopra, who after the Cairo and Beijing conferences recently stated that the common ground of all religious laws is their discrimination against women. Is Taoism, which attributes equal power to the female and male principles of yin and yang, more egalitarian than Confucianism, Buddhism, Judaism, Christianity or Islam, which appear more concerned about women's duties than their rights? In any case, if one takes into account the evolution of doctrine (recent years have even seen the development of a feminist theology, mainly in the Protestant world) and distinguishes reference texts from practices rooted in tradition and determined by state policies or ecclesiastical authorities, the influence of religion appears to have been decisive[9] and the secularization of states and societies is seen as a condition favourable to the assertion of women's rights like education, legal and economic autonomy, political citizenship, and later, contraception.

The conquest and codification of these rights have a history whose thread, interrupted by the previous point, I will now pick up again. Feminist associations existed in Europe and the United States at the beginning of the twentieth century and were organized as federations at the national and international levels. The International Council

of Women was set up in 1888 on the initiative of American women, and possessed 17 European sections in 1914. Travel, correspondence and international congresses enabled the emergence of a transnational feminist culture, and the concept of the 'new woman' (independent and creative) gradually crossed frontiers, reaching the colonies and other continents. This was the title of an essay published by the Japanese writer Hiratsuka Raicho, who founded the review *Seito* ('Bluestocking' 1911–16), in order to liberate women's talents. She went on to obtain political rights for Japanese women from the American authorities in 1945, and later devoted herself to the anti-nuclear movement.[10] This was also the title given to a Saigon-based review in 1930s Viet Nam, while in Egypt the interwar period saw the launching of the feminist journal *L'Égyptienne* ('The Egyptian Woman'). Constrained by the inequality of relations between nations, this international movement twice came to grief on account of war, while after 1945, feminism appeared to lose impetus in the West despite the long-term impact of Simone de Beauvoir's work *The Second Sex* (1949).

However, during the second half of the twentieth century, intergovernmental organizations (mainly the United Nations, and to a lesser degree the Council of Europe and the European Economic Community) played an important role in the development of equality between men and women.[11] This role evolved and became more prominent in the final decades of the century, after the United Nations had responded to issues raised by new feminists in Western countries (condemnation of patriarchy, the politicization of private life, demands for sexual autonomy and the right to family planning), by proclaiming 1975 International Women's Year, and by organizing, in Mexico City, the first conference on the situation of women in the world, as the prelude to a decade on the themes of 'equality, development and peace'. Taking its cue from feminist and women's organizations (whose numbers grew outside the Western world), from women experts from the 'Southern' countries, and from non-governmental organizations, the merit of the United Nations, whose member states were also increasing, was also to promote discussion in the decolonized world on the relationship between women, gender and development and to undertake action along those lines.

The San Francisco Charter and the Universal Declaration of Human Rights of 10 December 1948 both prohibit sexual discrimination, along with any distinction on the basis of race, colour, language, religion, opinion, national or social origin, in the enjoyment of human rights (extended to include economic and social rights), and fundamental freedom. This was thanks to campaigning by women's organizations united under the umbrella of the Inter-American Commission on the Status of Women and to the action of energetic women such as Eleanor Roosevelt (1884–1962), the widow of the American President, a tireless activist on all fronts, who went on to chair the United Nations Commission on Human Rights. The Charter and the Declaration constituted benchmark texts for the promotion of women's rights in the world, but their effectiveness was limited because they followed the legal tradition of speaking of the beneficiaries of rights abstractly and with no reference to their sex. Without sexual and procreative self-determination, the rights to life, liberty, dignity and security of person are not effectively guaranteed

for the female half of the human race (any more than is equality in marriage). Moreover, the transformation of the Declaration into covenants able to bind states parties was slow in coming (two covenants adopted in 1966 did not come into effect until 1976), and monitoring procedures lacked teeth. The United Nations Commission on the Status of Women had a limited mandate and no powers of investigation; it nonetheless gave an impetus to the ratification of specific treaties (on the political rights of women, the nationality rights of wives, marriage and the question of consent), and prompted by communist countries in the 1960s, it advanced the project of an instrument able to deal with women's rights as a whole.

The Convention on the Elimination of All Forms of Discrimination against Women (CEDAW), an amalgamation of the policies elaborated over a period of thirty years, was adopted in 1979. It was the first international treaty to view discrimination against women as distinct from other forms of discrimination and to give sexual difference legal status. In its 30 articles, the convention defines this type of discrimination in broad terms (including all limitations, such as family and sexual, on the equal exercise of individual rights) and makes provision for temporary special measures (legally binding) in order to promote de facto equality. The most important document to come out of the 'Decade for Women', CEDAW also had limited application. It had been ratified in 1995 by only 137 states, which were committed to the submission of national progress reports every four years. Over 40 states parties had entered substantive reservations as to its content.

Mexico City 1975, Copenhagen 1980, Nairobi 1985 and Beijing 1995 combined with the parallel NGO forums that brought together 6,000 women in Mexico and 30,000 in Beijing. These four conferences gave rise to a body of gender statistics, which raised the profile of the women and gender issues, shaped world public opinion on the themes of equality and development, and laid down guidelines, in declarations and action programmes, for international organizations and national governments. Without doubt, the most important outcome was the recognition of women's work (paid or unpaid), and the need for their active participation in development projects, which were often planned from a neutral perspective without any analysis of the effects on women and gender. In Nairobi, following a decade of specific programmes with disappointing results, emphasis was placed on the central role of equality (in terms of opportunity and legal rights) as the ultimate aim and as an instrument of peace and development. Two concepts and strategies that had been forcefully reasserted in Beijing also emerged: 'mainstreaming', or the incorporation of a gender perspective and of equality of opportunity between men and women in general programmes and policies;[12] and 'empowerment', designating both the strategy of giving power to women at all decision-making levels and the process by which they individually and collectively increase their power over their own lives and in society.

The changes that had come about in half a century of international legislation were clearly apparent in a radically new approach to women's rights in the 1990s, which emerged in response to the previously mentioned upsurge in violence and violation. The second World Conference on Human Rights (held in Vienna in 1993) affirmed that 'the human rights of women and of the girl-child are an inalienable, integral and indivisible part of universal human rights', opening the way for the identification of specific forms of violation (particularly the forms of sexual violence included in the December 1993 Declaration on the Elimination of Violence against Women) and for the recognition of a new generation of human rights, which included reproductive and sexual rights. Despite opposition from many quarters, the entitlement of every individual to reproductive rights was recognized by the Cairo conference on 'Population and Development', and the entitlement of women to sexual rights was recognized in Beijing, although without imposing abortion legislation on states parties. This huge victory for feminists throughout the world heralded a new era. However, for these rights to become effective, their full implications for civil, political, social and cultural rights needed to be followed through and appropriated by women.

Throughout the world today, all socio-economic indicators, with the exception of life expectancy, are less favourable for women than for men, and the development index needs to be adjusted to take into account the disparities between the sexes, as proposed by the United Nations Development Programme in 1995. As measured by the GDI (Gender-related Development Index), sub-Saharan Africa, Afghanistan, and a large part of South-East Asia are extremely low-ranking, and post-communist Eastern Europe has fallen back sharply, since sexual equality depends as much on the policies a state implements as on a society's income. Formal equality has progressed almost everywhere, but legal discrimination is still extremely widespread, mainly with regard to civil rights in developing countries. The family and its traditions are still at the hard core of female dependence, providing a backdrop to the gender division of labour, the overworking and physical coercion of women.

## FAMILIES: THE DECLINE OF PATRIARCHY

Patriarchy may be defined as a system in which men (fathers or husbands) dominate women, utilizing their labour (mainly domestic) and controlling their sexuality and reproductive capacity. It manifests itself in both the formation and composition of the family, in intra-family relationships (legal and everyday), and in the gender division of labour. At the start of the twentieth century, it existed throughout the world in varying degrees (in Africa, colonization wiped out the prestige of women chieftains and queen mothers along with the existence of women's associations). It is gradually disintegrating in places, but on a world scale, the family scene generally remains highly contrasted.

Depending on the level of education and urbanization, age at marriage generally rose in the twentieth century. However, the proportion of girls already married at a very young age (15–19) remains high, particularly in Africa (over 50 per cent in Mali and in Niger), and in Asia. In India, the legal system is experiencing difficulty combating the age-old custom of child marriage, while in Pakistan many young girls are married to men within their families, which increases their dependence. Pakistan is a Muslim country where there is little polygamy, unlike Muslim West Africa. In Nigeria, Mali or Senegal today, polygamy affects over 40 per cent of married women, but the lack of previous

surveys makes it difficult to measure the situation's evolution. Pakistan also practises the highly restrictive dowry system, in contrast to the bride-price still paid by the majority of African men to their wife's family to 'compensate' the loss of a source of labour and reproduction. For a long time, this was paid in goods (especially in head of cattle) or in labour, then increasingly in money with the monetization of the economy, but although recently some governments have occasionally prohibited the practice, it remains socially embedded. In both cases, marriage for a young woman very frequently means going to live with her husband's family, where several generations, and sometimes all the brothers and sisters, live together.

In Europe, North America and Australia, the institution of marriage at first grew stronger in the twentieth century, with cohabitation and illegitimate births declining among the working classes and the nuclear family becoming more widespread. It was called into question from the 1970s onwards (in particular by the feminist movement), and this was reflected by the proliferation of often-prolonged cohabitation among young people (especially in Sweden and France), an increase in celibacy, and a rise in the divorce rate, although strictly Catholic Ireland did not legalize divorce until 1996. This challenge to established ideas gave rise to, and accompanied, a wave of reform that led to the incorporation into the private law of Napoleonic code countries, belatedly, after their common law counterparts, of the idea of equality between husband and wife and to the elimination of the concept of head of the family. Civil law henceforth authorized a multiplicity of female roles and family models, but the freedom won has sometimes been at the cost of solitude (divorced men remarry more frequently and more quickly than women) and relative poverty, especially in the case of single-parent families. Similarly, tolerance towards homosexuality, whether female or male, has considerably increased in the West over the last 20 years, although homosexual unions have been recognized by only a few countries (here again, the Scandinavians led the way), but the WHO did not remove homosexuality from the International Classification of Diseases until 1992, and in numerous states, it is ignored as a social reality or is a punishable offence (even by the death penalty).

The idea that a married woman belongs to her husband governs social relations, and, in a number of countries, the law itself. The most extreme expression of this is the custom of *suttee* (whereby the wife commits suicide after the death of her husband), still practised at times in India despite the fact that it is prohibited. In Arab countries, modern law, which for the most part carries more weight than Muslim law *stricto sensu*, does not apply to the domestic citadel of the family and to women, pawns in the battle between modernists and traditionalists. Women remain subject to codes of personal status directly inspired by *sharia* (Muslim law), sometimes in its most regressive interpretation (Plate 52). In these countries, as in other states in Africa and Asia, women suffer constraints on their freedom of movement (to the extent of being confined to the home) and must submit to dress codes which emphasize their enclosure (veil or *chador*). Constraints of this kind, the history of which still has to be charted (the current upsurge in religious fundamentalism shows clearly that political climate is just as important as cultural tradition), are in no way comparable to those associated with 'beauty culture', even though this was partly brought about by the cosmetics industry which,

from its beginnings in the United States in the 1920s and 1930s, invaded Europe post-1945, and today is spreading throughout former Eastern-bloc countries and starting to take hold in Asia.

Domestic violence is universal and remains a major cause of injuries inflicted on women and of female mortality in the world. Long shrouded in secrecy, this phenomenon has left few traces, mainly in the form of police or court records, which are only just beginning to be examined from the angle of women's rights. Its history has not yet been written, but a start has been made on raising awareness of its multiform reality. In Sweden, the ban on husbands beating their wives dates back to 1858, but in the rest of Europe, in the United States, or in Latin America, where domestic violence is rooted in a very macho culture, domestic violence mainly takes the form of battering, marital rape (a recent concept and an act which has been made a criminal offence in some democracies), and sometimes murder, committed by a drunken husband or partner. In many developing countries, violent acts may also be committed by members of the extended family (for example, mother-in-law) and may take extreme forms; such as the honour killings that often go unpunished in Pakistan, or bride-burning in India resulting from dowry-related conflicts. It is accompanied by social violence carried out by men against single women, those whose behaviour is considered unconventional, or women classed as prostitutes. There is also violence fostered by many governments in a general political atmosphere of repression.

Primarily controlled by men, prostitution is an activity that survives by violence, and its existence tends to perpetuate patriarchal family structures. It is an extremely ancient and widespread practice, which has existed in various forms on all continents (prior to 1949, China was the largest market of human beings in the world), and it endures today. It is a means of survival for women at the local level, but increasingly supplies an international sex market, which prospers due to economic disparities between regions of the world (Eastern Europe, impoverished in the 1990s, supplied its contingent, alongside Asia, Brazil and Nigeria) and to sex tourism. The female body is a commodity. It is also subjected to a quite specific form of violence, i.e. the genital mutilation carried out on 40 per cent of African women in around 30 states stretching from Mauritania to Egypt and Somalia. Excision (removal of the clitoris and the labia minora) and infibulation (in addition, the removal of a section of the labia majora and the stitching up of a large part of the vaginal orifice) are extremely damaging both mentally and physically. Such mutilation is associated with ethnic or religious traditions about whose origin little is known, and it is intended to diminish the sexual appetite of the woman and 'cleanse' her body, which is subordinated to the sexual pleasure of the man alone, and to guarantee virginity until marriage. These practices are carried out by women on girl infants or girl children whom they wish to incorporate into their communities (two million victims every year at the present time). They were condemned from time to time by missionaries or colonial powers, along with other initiation rituals, but have more often than not been tolerated in the name of 'respect for tradition' or ignored altogether. For a long time, the independent states did nothing and the WHO (World Health Organization) invoked the social and cultural context before taking a stand in 1982. The condemnation of these practices by Western feminists in

the 1970s irritated some African women's movements, but other African women, such as the Senegalese Awa Thiam, worked and are still working towards their eradication. Since the 1980s, many states have adopted legislation to counter these practices and some, such as Burkina Faso, have been carrying out effective campaigns even down to the village level, out of consideration for the health of young girls and future mothers.

## MOTHERHOOD AND WOMEN'S WORK: TOWARDS AUTONOMY

All societies have valued and continue to value motherhood, which confers dignity on women. At the beginning of the twentieth century, Western feminists demanded rights and social protection in consideration of this special status. Other women used it to resist oppression, such as the Argentinean mothers who demonstrated every Thursday on the Plaza de Mayo, wearing babies' white flannel nappies as headscarves, to condemn General Videla's dictatorship (1976–83), and demand news of their 30,000 missing ('disappeared') children.[13] But the place of motherhood in the lives and identities of women became extremely varied in the twentieth century with contrasting situations in developed and developing countries, from continent to continent, and from country to country.

Europe had virtually come to the end of its long demographic transition[14] by the beginning of the twentieth century, and the birth rate remained low throughout the century – except for the baby boom following the Second World War. The low birth rate was nevertheless fought against by dictatorial regimes, and by one democracy – France, which brought in policies that were a mixture of controls and incentives in order to encourage births. In North America, the birth rate was also low, and it remained a land of immigration. During those decades in both Europe and North America, however, motherhood underwent three major changes that promoted the autonomy of women vis-à-vis their biological determination and conjugal ties. First, the improvement in medical care and social protection set up by welfare states (although less protective in the United States) led to a sharp decline in maternal and infant mortality rates (respectively, from 5 per 1,000 to less than 10 per 100,000 births, and from over 10 per cent to less than 10 per 1,000), and provided social assistance for the function of reproduction (paediatricians, psychologists, nurseries and primary schools). Secondly, the development of the consumer society (from the 1950s and 1960s onwards in Europe, and earlier in the United States) considerably alleviated household tasks and intellectualized what is sometimes described as the 'the profession' of mother, so complex had the activities of motherhood become. Finally, the adoption – often slow and difficult in Catholic countries (1960s and 1970s) – of laws authorizing contraception and abortion, a major revolution, gave them control over their fertility and their own bodies and undermined the old system of domination and mental representations. However, one needs to be aware of social and racial disparities in maternal status (especially in the United States), of the deterioration of social systems in former Eastern-bloc Europe over the last ten years, and of the difficulties encountered in having children in some countries like Germany and Japan, where little is done to make work compatible with motherhood

and the average number of births per woman is less than 1.5.

Major changes also took place on other continents, and often more quickly, especially as far as the fertility rate was concerned. On the urbanized continent of Latin America, the transition occurred early in predominantly white countries and became widespread after the Second World War. The level of fertility (2.7 children per woman at present) decreased throughout the continent from the 1960s onwards through a combination of the modernization of the wealthy sectors of society and of a 'Malthusian' approach to poverty, which made use of the pill and, even more frequently, of female sterilization. Brazil is a case in point. The spread of Malthusianism, which enabled women to escape the risk and burden of repeated pregnancies and to feed their children better, was encouraged by the authorities and by the United States, fearing the social tensions of a 'demographic bomb'. The issue of the consent of women and couples to national and international family planning policies should be raised, in fact, especially with regard to Asia, which has seen a sharp fall in the birth rate per woman over the last four decades (the present average is 2.6 children per woman), and renewed attempts to impose a one-child policy in China. There, as in India, Pakistan, or South Korea, the lower birth rate has sharply highlighted the time-honoured preference for male children (shared to a varying degree by many societies). It would appear that around 100 million females have been eliminated due to the abortion of female fetuses (detected by amniocentesis, and over the last two decades, by ultrasound scan), the infanticide of female babies, mistreatment, or neglect.

Sub-Saharan Africa has long been presented by demographers as an exception. Here, the fertility rate still exceeds five children per woman due to early and widespread marriage, little recourse to contraception (even in urban areas, where middle-class women can find cheap domestic staff or call on the free labour of young female relations from rural areas), and a value system that favours births. However, the recent example of Kenya, where new property and inheritance laws have considerably increased women's rights and information campaigns and new services have been expanding in rural areas, has shown that the fertility rate can fall sharply in Africa too. Even so, this is where maternity-related risks have been highest, due to a very low level of medical care, serious consequences such as vesico-vaginal fistulae, which leave women incontinent and ashamed (sometimes repudiated), a particularly high maternal mortality rate (from 0.5 per cent to over 1 per cent[15]), and only too often, the grief of losing a sick or undernourished child. AIDS, the scourge of the final decades of the twentieth century, has caused great ravages among men but also increasingly among women, who are not in a sufficiently strong position to refuse sexual relations or to force men to wear condoms. However, throughout the world, improvement in the health and health education of women – the ones who provide care and the instruments of modernity – has contributed to an improvement in the health of entire populations.

Childbirth increases the domestic workload of women. In rural areas, this work is traditionally carried out in addition to work in the fields (especially in Africa) and is time- and energy-consuming: fetching water or wood, grinding grain, and cooking. As happened in Africa, where

colonization and development of crops for export increased the burden on women and deprived them of the fruit of their labours (monetized by men), the situation of peasant women tended in the twentieth century to deteriorate in poor countries, even in independent states, and conventional forms of forced labour (to repay debt, for example, in Pakistan or India) persisted. Towns and cities everywhere attracted and continue to attract people, owing to the opportunities they offer, even as they destroy previous social links and ways of life and reveal stark inequalities. To a greater extent than domestic service – which became feminized in Africa in the twentieth century (from houseboy to ayah), and frequently led to the gross exploitation of younger and older girls from rural areas or distant countries (Filipino maids in the Middle East, for example) – it has been the so-called 'informal' labour activities that have enabled women, many as heads of household (up to 35 per cent of households in the Caribbean), to subsist and to achieve a certain level of independence. This has long been the case in certain towns in West Africa, where women sell at market what they produce, make or collect, or run the trade in food or craft items, locally and at times further afield. Today, many African cities survive thanks to unflagging and pitifully remunerated female labour. In the more urbanized and industrialized Latin America, as in South-East Asia, women are also employed as manual workers, supplying textiles or electronics industries 'relocated' from wealthy countries with cheap and dexterous labour, and sometimes taking up modern occupations in the tertiary sector. The well-known brands of clothing or sports goods brands sub-contract the manufacture of their products, which are made by young women or children for a pittance (less than one hundredth of the selling price), particularly in Indonesia, China, and Mexico, to the general indifference of most consumers in wealthy countries.

In developed countries, where women today make up 41 per cent of the working population (or occasionally more, as in France), work was and is a necessity for many. Although, women have always worked in agricultural societies and the poorest of them played a part in the industrial revolution, paid work outside the home as a source of independence represents a conquest of the last three decades of the twentieth century. This occurred after the slow democratization of the middle-class stereotype of the mother in the home, which reached its high point after the Second World War – an exception to this being the communist countries which always fostered women's work. At the same time, working women, who at the beginning of the century were mainly land and manual workers, for the most part became employees in the highly diversified and rapidly expanding tertiary sector. Like men, women benefited from the social gains of the century (labour legislation and protection against risks to life), but equality at work, constantly called for, was not achieved. At the end of the 1970s, the economic crisis that brought to an end the 30-year boom period begun in the wake of the Second World War maintained, reinstated or accentuated the disparities in employment and wages (women being most vulnerable to unemployment and the demands of flexibility), with the exception of the most highly educated, who benefited from a tendency towards egalitarianism, only to come up against what is known as the 'glass ceiling'.

## ACCESS TO KNOWLEDGE AND POWER: A CONSTRUCTIVE PATTERN OF CHANGE

Historically, access to learning has been based on segregation by class and sex: why teach the poorest individuals (condemned to the hardest manual labour) or girls destined to perform the domestic tasks learned from the women of the family? Why give them the same teaching in the same schools? In Europe and North America, illiteracy had been overcome – earlier in some places, later in others – by the end of the nineteenth century, as primary education became widespread. However, for a long time, there were fewer girls in secondary or higher education, where the doors of certain establishments were closed to them, or they were confined to specific courses that did not provide the same employment opportunities. Over the last thirty years in Europe, North America and the southern part of Latin America, women have become more numerous and successful in education and less prone to functional illiteracy. However, in developing countries, the 'education revolution' has been slow in coming and was very unevenly spread, except in socialist states such as Maoist China or Cuba under Castro, which rapidly and extensively provided both sexes with schooling. Girls, shunned by colonial schools, which often superimposed their own interpretation of female dependence, for a long time received less schooling than boys. The illiteracy rate among women (who today make up two-thirds of the world's billion illiterate adults) is still extremely high in the majority of African states (at times, as high as 90 per cent), and in countries such as India, Pakistan, Afghanistan, and Laos. However, there is a widespread consensus in favour of education among the international community, which provides aid to states at their request. This situation is changing rapidly for the younger generations. With a few exceptions – such as Afghanistan, where the Taliban closed girls' schools when they came to power in 1996, or African states affected by war or plagued by severe economic recession – an increasing number of girls (including in rural zones) are receiving a few years of schooling. This will have an impact on the future in many different ways, including an improvement in family health, decline in the fertility rate, and greater independence for women.

The issue of the gender bias and, even more importantly, the sexist content of textbooks and school curricula was first raised by feminists 30 years ago and was not solely the concern of wealthy countries. At every level, women's issues were rarely considered and their achievements (artistic, cultural and political) were ignored. This hampered the growth of awareness by girls of gender inequalities and stood as an obstacle to their identification with female role models. In all societies, the voices of women – painters, musicians, writers, discoverers, activists, female politicians – have always had more difficulty in making themselves heard, claiming universality, and being acknowledged. Since the foundation of the Nobel Prize in 1901, fewer than 30 women have won prizes, out of more than 600 individual awards. However, Nobel Peace Prizes were awarded to the Burmese Aung San Suu Kyi (Plate 53), in 1991, and to the Guatemalan Rigoberta Menchú, in 1992, and these recent nominations along with the cultural affirmation of women in wealthy countries and elsewhere, reflect the current pattern of change. A similar situation has also been noted in politics.

In traditional societies as in organized states, politics, the public domain *par excellence*, has traditionally been a male concern. In West Africa, where women, such as Ibo peasant women or tradeswomen in towns, enjoyed a certain level of autonomy through the management of their own business, politics became even more of a male preserve with the advent of colonization, which destroyed their unity and way of life and provoked revolts. In North America and Europe, the phenomenon was also exacerbated by the establishment of democracies that refused to grant to all women the privileges enjoyed by some. However, at the same time, this gave rise to suffragist organizations, which called for the right to vote and to be elected, in the name of the equality of all individuals and the qualities specific to women (Plate 54). The first state in the world to give women the status of citizens was New Zealand, in 1893, and the first European state to do so was Finland, in 1906. Almost everywhere, and particularly in France, where women acquired political rights in 1944, almost one century later than men (1848), resistance from male and political spheres was extremely strong – stronger than the resistance to the integration of the poorest sectors of society, although usually weaker than opposition to the integration of people of other ethnic origins. There were also numerous expedients, such as introducing the right to vote in stages, granting suffrage to some (such as soldiers' widows, female military personnel, mothers with several children) and barring others from it.

It was at the end of the 1950s, in the wake of decolonization, that the right of both men and women to vote and to be elected became widespread throughout the world (Plate 55). In 1959, Aoua Keita, a midwife and activist in Mali's Women's Democratic Assembly, became the first woman in French-speaking Africa to be elected to the Constituent assembly of her country.[16] With the exception of Kuwait, and on a world scale, going beyond the scope of T. H. Marshall's chronological model,[17] political equality was achieved from the 1970s onwards, before civil equality and before the acquisition of social rights. But this equality was limited, not only by the absence of real democracy in many countries, but also by the use women made of their rights and the difficulty they experienced in rising to positions of power within legislative or executive authorities. On the one hand, women, who for a long time were more inclined to abstain from voting and were more conservative than men, or who followed family opinion, needed time (sometimes several decades) before they voted in a truly autonomous way. Since the 1980s, in Germany, France and the United States, women have proven to be more progressive and hostile to any form of extremism. On the other hand, despite the success of outstanding female politicians, who, incidentally, have rarely supported the cause of women, executive or elected offices have remained male bastions. Nonetheless, we should mention certain women who were the political heirs of their fathers or husbands: Sirimavo R. D. Bandaranaike of Sri Lanka, the world's first female prime minister (1965–70 and 1971–77); Indira Gandhi, prime minister of India from 1966 to 1977 and from 1980 until her assassination in 1984; Corazón Aquino, the 'Madonna of the Philippines', who held office from 1986 to 1992; and Benazir Bhutto, the 'Queen of Pakistan', prime minister from 1988 to 1990 and then from 1993 to 1996. Moreover, there are also noteworthy self-made women: Golda Meir, the 'Grandmother of Israel' and prime

minister from 1969 to 1974 (Plate 56); and Margaret Thatcher, the 'Iron Lady', who governed the United Kingdom from 1979 to 1990.

In reality, only deliberate quota policies have made it possible to bring about any significant increase in the representation of women in parliaments. Such a policy was introduced in the 1980s by the Scandinavian nations, where women also rose to the highest executive offices (the former Norwegian prime minister, Gro Harlem Brundtland, became Director-General of WHO in 1998). Their example was followed over the next ten years by several states in Africa and Asia, including India, where one-third of seats on village or town councils were henceforth reserved for women, and by France, which committed itself to a strategy of *parité* (equal access by men and women). This is a positive pattern of change. However, looking beyond electoral politics, it is the 'empowerment' of women (the way in which they take charge over their lives) that will build the world of the twenty-first century. An uncertain world, but perhaps one in which there is more equality between the sexes, more sensitivity to wealth sharing, and more openness to the intermingling of spaces, powers and cultures. The twentieth century blazed the trail and showed that nothing can ever be taken for granted. It is now for tomorrow's women and men to press on tenaciously and with vigilance.

## NOTES

1.   See the proceedings of the 17th (Madrid), 18th (Montreal) and 19th (Oslo) International Congresses of Historical Sciences.

2.   Illustrated, e.g., by Catherine Coquery-Vidrovitch, author of numerous works on Africa, in French and English.

3.   I presented this thesis in the volume devoted to the twentieth century in the collection entitled *Histoire des femmes en Occident*, Plon, Paris, 1992.

## YOUTH

### *François Dubet*

**INTRODUCTION**

The way in which youth is experienced varies considerably according to the historical and social context. The new manner of perceiving and understanding youth that has evolved in recent years is closely associated with a longer period of education, the weakening of social structures and the increased interaction between the mass youth culture and the mass youth market. Paradoxically, young people are most independent and most highly thought of in Western societies, precisely where they are the least numerous.

The advent of the modern era has given particular significance to youth. In societies dominated by social change, young people have been identified not only with a better future but with decadence as well. The way youth is defined often owes more to ideology and the imagination than to reality. As most of the fears and aspirations of a society are projected on its youth, young people as a category must be considered in a historical perspective, and their conduct and behaviour patterns studied in light of the phases and stages of social development.

**Adolescence and youth**

Youth is both a bio-psychological concept – in which case it is preferable to speak of adolescence – and a social fact (youth proper).

Adolescence is a period of physical, psychological, emotional and cognitive maturation. It is the transitional stage between childhood and adulthood, between the age of dependence and that of the entry into an autonomous and responsible adult state. Children in all known societies have to face adolescence, and most societies consider it a period of uncertainty and unease during which individuals experience an identity crisis, often stemming from the contrast between their intellectual and physical abilities, on the one hand, and their status in society as minors, on the other. Adolescents naturally sever their ties of loyalty and obedience to their elders and begin claiming a new degree of autonomy. Through attachment to their peers, they discover their power and their independence. In psychoanalytical

terms, this stage of life is considered to correspond to an 'Oedipal reactivation' that disrupts identity and self-image. In most traditional societies, adolescence is therefore delimited and punctuated by rites of passage marking the transition into adulthood. Rites of passage are ceremonies that transform adolescent boys and girls into adults. The aim of such traditions as the medieval ceremonies associated with chivalry, the changing of family names, and female initiation rites that reveal adult secrets, is to reduce and control the period of adolescence and to ensure a harmonious passage to a pre-defined adult state with distinct sexual and work roles. Quite often, traditional societies tolerate some excesses by young people when they are reassured they will not destabilize the social order.

The notion of youth, in the strict sense of the term, comes to the fore when the intermediary stage between childhood and adulthood is drawn-out and dissociated from adolescence proper. In modern societies, where one is considered a young person up to the age of about 25, the concept of youth is quite extensive because individuals are no longer considered in terms of their psychobiological situation but in terms of their social situation. A young adult of one hundred years ago, for example, would today be considered a young person. The age at which a person starts to work or marries is thus advancing as societies develop. Youth is a function of modernity because this lengthening of an intermediary age in the life cycle is due to economic and social factors. In modern societies, the period of formal education has grown longer and longer, and in many societies, half the population pursues an education beyond the age of 20. In fact, in many countries, anyone below 30 years of age is considered to be 'young'. Furthermore, societies of 'ascription' have given way to societies of 'achievement', the status of individuals being no longer wholly inherited, and mapped out by a strict destiny, but acquired by the individual during that long formative period called youth. In modern societies, people do not become doctors or workers because they are sons or daughters of doctors or workers, but because they have acquired the necessary qualifications. Even though opportunities for acquiring a particular status are largely inegalitarian, it is nonetheless true that an individual constructs his or her own adult status. The same applies to the choice of husband or

wife. With the decline of arranged marriages, each person forms his or her family within objective social determinations. There are thus two contrasting dimensions that characterize youth – uncertainty and the need to project oneself into the future. For demographic and social reasons, today's youth is constantly evolving in those societies engaged in a process of development, as can be seen in the internationalization of youth culture and the student demonstrations in China, Korea, Japan and Latin America. Youth is thus beginning to extend beyond the bounds of its modern Western framework.

The history of the sociology of youth coincides with the evolution of youth itself. Indeed, this branch of sociology has grown and changed as the period of youth and preparation for adult life has grown longer, with the postponement and growing uncertainty of entry into active life and with the proliferation of youth and training policies. The sociology of youth is, however, very often linked with related topics, such as youth and delinquency, youth and education, youth and work, youth and culture, youth and politics, youth and the family, or youth and mobility.

The general survey by O. Galland,[1] which offers a very clear and well-documented account of the sociology of youth, follows this principle, thereby reflecting the multifarious experience of youth. With the exception of the anthropological problem of adolescence, the sociology of youth encompasses all the branches of sociology that deal with youth. The subject of youth sociology, i.e. relationships between the generations, accounts for only a fraction of the studies. Youth is perceived rather as a 'condition' defined by the nature of the fields, institutions and policies through which it can be studied.

Several problems and images of youth can be portrayed, depending on the general context in which they develop. In as much as youth is associated with modernity and development, we must consider those stages.

**The advent of industrial societies**

For a long time, youth was a privilege of the dominant classes, which had the luxury of deferring entry into the work world and indulging in a long period of education and training. Youth-related problems emerged with the advent of industrial society and modern nations. The 1930s were marked, in the United States in particular, by some major studies relating to gangs and urban marginality. Youth emerged as one of the subjects of urban sociology, that is, the sociology of the processes of crisis and change triggered by modernization. Youth provided the litmus test for those mechanisms because the immigrant groups that started to penetrate American culture and society were often quite young. Many famous surveys[2] constructed models for the interpretation of young people's behaviour in terms of social disorganization, migratory changes and urban life. Gangs and the sociability of youth in big cities were forms of solidarity and provided resources that enabled young people to survive and to adopt an identity when caught between traditional cultures and modern societies. Many studies on immigrant youth often unwittingly reflect this tradition and perspective. It must be borne in mind that many young people today are faced with the ordeals of social acculturation, particularly the young Arabs, Africans, Caribbeans, and Latinos in Europe and North America. The capacity of

integration within industrial societies and their institutions is evaluated with respect to young people. It is also in connection with youth that questions arise as to how one becomes English, American, Canadian, or French or whether modern societies are civilizations of integration or classes of minorities. In the first case, the gang is considered to be a step towards integration; in the second, it is perceived as the expression of a community that lives outside of the predominant society.

In general, sociologists observe a conflict between the high potential for cultural assimilation resulting from the pressure of mass culture and the low level of economic integration due to practices of segregation. In poor inner city areas of English-speaking countries or in destitute Latin American neighbourhoods, revolt is growing among young people who want to integrate but who cannot be absorbed by the economies of Western societies.

Many of the problems of youth are related to development. Youth involved in urban violence and drugs are often seen as victims of unemployment and other social problems. In most developed societies, youth policies have evolved into social and training programmes that attempt to demonstrate how young people can be productively integrated and trained where previous methods have proven obsolete. However fascinating the study of post-modernity in post-industrial societies may be, it should not be forgotten that much of humanity is still experiencing problems related to their entry into urban industrial society.

## YOUTH, MASS SOCIETY AND YOUTH CULTURE

Youth only really came to the fore as a specific field of sociological study in the 1950s and 1960s, an era marked by the 'rise of youth' and by the appearance, in all Western countries, of a new type of young people from the educated middle classes. During this period, several phenomena emerged such as the lengthening of the period of youth and the youth culture as a sign of cultural modernity. In fact, to be modern was to be 'young'. The work of T. Parsons, S. N. Eisenstadt and E. H. Erikson illustrates the thinking at that time.[3] These specialists stressed the importance of a period of life in which one's personality becomes more autonomous and more detached from old values. That is why youth is always perceived as 'dangerous' in varying degrees by broad sectors of society. Once again, youth was identified with modernity, that of the middle classes, who were exposed to the mass media, upheld the values of personal independence and self-fulfilment and devoted many years to their education. Youth culture appeared to define the 'adolescent society'[4] and imposed its own collective identity, distinct from that of adults, during a period fraught with intergenerational conflict. Youth culture was considered to be a form of socialization at an age of life marked by ambivalence towards the law and the postponement of adult commitments. It was a way of managing the strains and 'crises' of prolonged youth in the modern world. In countries with shrinking populations, however, the image of youth remained globally positive.

Since the release of the first rock and roll recordings, youth culture has become one of the essential features of the cultural landscape. The vast majority of young people form a part of this culture, which distinguishes individuals

according to their styles, tastes, clothing, etc. To belong to a specific generation is an essential element of identity. To a large extent, modern youth culture constitutes the first world culture. Elvis Presley, the Beatles (Plate 57), the Rolling Stones, among others, became the stars of a universal culture widespread in Western countries but also throughout the former communist countries of Eastern Europe and the Third World. Of course, this culture is not homogeneous because it is adapted to local contexts leading to the creation of specific musical styles, like raï in Arab countries. It is also highly diversified from one social group to another, each group being distinguished by its particular tastes and passions. Not all young people dress in the same way, but a general style of dress and consumption has become the rule among youth worldwide. In just a few decades, youth fashion has developed into a large economic and cultural market. Tens of millions of young people listen to rock, hundreds of thousands play it themselves in some capacity, and this mass culture has become a means of expression associated with the sentiments and experiences of those actively involved in society. It is a culture that was optimistic and hedonistic in the 1960s, marked by protest in the 1970s, and desperate and violent in the 1980s. Youth culture is not only the result of the commercial strategies of large corporations, but also a form of autonomous expression, which explains why authoritarian regimes have always viewed it with distrust. Youth culture has been associated with all the major events of the last 40 years.

The sociology of juvenile delinquency also changed as youth was becoming established as a collective mass experience. The theory of deviance developed by Robert Merton greatly influenced sociologists of the period. Merton considered juvenile delinquency the outcome of tension between a mass democratic culture, which required each person to be fulfilled and to succeed, and a social structure that locked individuals into their existing affiliations and offered them no opportunity to change their lives. Youth problems were thus one of the most striking manifestations of the conflict between social inequality and the democratic ideal. Therefore, the sociology of youth could be defined as the analysis of the encounters between youth and social structures related to opportunity.[5] Juvenile delinquency, as epitomized by Hell's Angels, Rockers, Soviet 'hooligans' and Teddy Boys, was not seen as an effect of social disorganization but as the outcome of contact between a rigid social structure, especially for the working class, and a mass culture that aspired to middle-class lifestyles. In France, the advent of youth as a mass phenomenon in the 1960s led to a number of studies, including E. Morin's well-known articles (1966), on youth culture. Morin's work must be compared with more structural approaches that challenged the image of a mass youth culture from the point of view of class differences. This debate lay at the heart of the sociology of youth during the period of cultural modernization, as embodied by the 'teenager'.

**Can youth be considered a social movement?**

May 1968 in Paris (Plate 58) and the protest movements on American campuses gave a new twist to the study of youth by associating it with the sociology of social movements and change. Were young people new players on the cultural and social scene? The image of young people

adulating the consumer society was replaced by that of the critical, pugnacious youth of the great demonstrations against the Vietnam War, the youth of the Woodstock counter-culture appealing for brotherhood and a return to nature (Plate 59), and the politicized radical youth of Germany, France and Italy who dominated the universities, the cradles of the new social movements of the 1980s. The rock concerts and rallies that sometimes served to express opposition to authoritarian regimes are noteworthy. For a few years, the sociology of youth was the sociology of counter-culture and the sociology of student movements. Scholars such as Margaret Mead, K. Keniston, A. Touraine and G. Vincent engaged in these types of inquiry.[6] Two major theories predominated in Western societies: youth as a social force able to transform the culture of industrial societies, and youth as a new player on the political stage, capable of taking up the torch of protest abandoned by the worker's movement, as suggested by Marcuse. The first hypothesis was advanced by Margaret Mead, who claimed that because of youth's uncertainty and low level of integration, it was building new utopias distinct from the values of capitalist industrial societies that would eventually lead to post-materialist values. The second theory was embraced by many left wing movements, some of which slid into terrorism, particularly in Germany and Italy.

However, we must point out the following paradox: while youth has become an essential element of contemporary societies, the youth movement seems to be relatively unorganized. The major cultural, religious or political youth movements that carried great weight until the 1950s are now unable to attract great numbers of young people. Should we regret or welcome this evolution? On the one hand, it can be viewed as a positive development, because many youth movements used to be associated with dictatorial parties, making them not so much youth movements as manipulated masses of youth. Today's young people feel both the weight and attraction of modernity, and solitude is perhaps the price to be paid for individual autonomy. On the other hand, this evolution may be regrettable because contemporary societies allow one to be 'alone in a crowd', and many young people suffer from isolation and the absence of moral standards. Suicide is a major cause of death among young people.

**THE CRISIS YEARS**

After the years of consumerism and protest came the crisis years, which primarily affected young people in the rapidly changing systems of education and the work market.

The time frame of youth has continued to grow longer in all Western societies in degrees that vary mainly according to the importance attached to higher education. For positive reasons associated with the recognition of young people's autonomy, and for negative reasons linked to the difficulty of starting work in a stable way, youth nowadays extends well beyond the period of adolescence. In this connection, it is possible to speak of the 'juvenilization' of modern societies, and a longer period of youth has ceased to be the preserve of the middle classes and of students alone. Youth has been constantly accorded increasing value, and this has affected the definitions of the various stages of life. The growing ascendancy of the education system is largely associated with this phenomenon. The historical perspective highlights

the growth of youth as a mass phenomenon and the weakening of rites of passage or the emergence of substitute rites that can no longer be considered fully genuine. Youth is valued. It is a time of personal experimentation, of living together as a couple, of having several jobs and a measure of freedom associated with the 'irresponsibility' of youth. However, owing to unemployment, job instability, and the declining value of a university degree in terms of earning-power, youth has also become extended. Indeed, it is increasingly difficult to become an adult in the modern world. In recent years, the study of youth has focused on examining the ways and means of entering adulthood and finding one's first job. The studies have often been associated with the evaluation of social policies on youth and in particular with the following up of cohorts of young people who have been through various training or qualifying courses. Many studies have highlighted the new stages of this adolescent moratorium, with the new phases of family cohabitation and frequent job change.[7] Other phenomena revealed by studies are late marriages and postponement of births. Dependence on institutions and the family has also increased, contributing to the 'blurring' of relations between generations. Many young people are in fact adults who cannot reach adulthood. In countries with greatly developed higher education such as the United States and France, the time spent studying is increasingly extended so that the level of academic qualification will afford protection from unemployment or guarantee a status that is considered respectable. In certain cases, a sort of student proletariat is developing that enrols in a university to prepare for a place in the unemployment queues. In that regard, national situations vary greatly, but unemployment rates for young people (like for women and even more so for girls) are extremely high. Many young people feel that their society is closing the door on them and forcing them to stay young.

The sociology of youth cannot be reviewed without reference to work on the political socialization of young people.[8] Political affiliation hardly occurs automatically. The nature of youth experience itself affects political choices. It has been noted that young people change their electoral choices frequently before adopting a stabile political position. Clearly there is no homogeneous youth vote since young people are a mass of individuals. Withdrawal from politics does not necessarily imply a decline in group action, as evidenced by studies of movements among high school students in France, who are still very highly motivated to act but whose commitment seems to be based more on values than on ideology.[9] While youth commitment is fleeting and no longer seems to be controlled by a hyper-politicized youth intelligentsia, other forms of involvement in collective action seem to be developing on the basis of more personal moral problems. The sociology of youth is associated with the study of post-materialist cultures as evidenced by young people's sensitivity to humanitarian and ecological causes, and to combating AIDS. On the other hand, young people can be violent in expressing their fear of traditional and national communities being destroyed by modernization and the globalization of trade and communication. They can become skinheads and adopt far-right ideologies to varying degrees.

The rise in the problems of marginalization has led to a wealth of research on the most disadvantaged young people, those belonging to the underclass, especially young people of immigrant origin. In collective representations, they embody the principal difficulties engendered by economic crises, urban transformations, and the effects of mass education. Generally speaking, there are two main views on the subject. The anthropological approach emphasizes the processes of acculturation and cultural crisis encountered by young people from immigrant families. This has given rise to the theme of 'ethnicity' and the assertion of community-based cultural and social identities in the very heart of modern societies. As these young people cannot become part of society, they retreat into a subculture of identity and conflict, as exemplified by rap and reggae. The opposing view emphasizes the strains engendered by the 'conflicts' between the considerable cultural assimilation of the young immigrants and the high level of social exclusion to which they are subjected. This view stresses the aspects of anger and revolt among the young people of immigrant origin and the formation of 'marginality', which is appearing as a new form of popular awareness as the traditional working-class world declines.

## YOUTH AROUND THE WORLD

The situation outlined above only arises in industrial or post-industrial developed societies. In other regions of the world, young people make up the majority of the population. Yet youth does not have the same implications for all of them. Some young people, who belong to the middle and upper classes, identify with Western youth; they try to look and behave like them and often experience identical problems, notably those associated with longer schooling. However, the vast majority have a completely different experience of youth. They must work from an early age and are cramped by structures and traditions that severely limit their autonomy, particularly regarding the choice of a spouse, cultural freedom, and the ability to innovate. These young people are actually deprived of their youth. They often constitute a proletariat within the proletariat (Plate 60); increasingly subject to unbridled economic exploitation, they struggle for survival and sometimes find themselves in a situation of such dependence and poverty that they have only their bodies to sell.

Let us not lose sight of the fact that the emergence of youth as an independent experience remains largely the 'privilege' of sufficiently developed societies. For other young people, youth is either only a short stage in their lives or a time when their exclusion from society is accentuated.

## CONCLUSION

The last two decades of the twentieth century have therefore witnessed a reversal in the optimism of the years of growth and of personal and collective liberation. The 'modern' youth of the 1960s and the 'critical' youth of the subsequent period of revolt are being replaced by youth in crisis. The sociology of youth is associated with the sociology of deviance and urban sociology and is becoming the sociology of social problems much more than the sociology of cultural and social change.

The sociology of youth has developed considerably and no brief review can do justice to the work published in this field. The mechanics of entry into active life and the sociology

of the various age groups are of great interest to researchers; our understanding of these subjects is being built up gradually. Age and gender divisions and cultural definitions of identity will assume greater significance as traditional legal barriers rapidly become unstable and as the period of youth continues to grow longer. At the same time, however, youth is becoming a sort of central figure in the social experience, for, as its borders become blurred, the characteristics of legal uncertainty and the characteristics of 'passage' are extending beyond the youth experience itself. Adulthood is ceasing to be the only benchmark.

## OLDER GENERATIONS

*Tampalawela Dhammaratana*

### INTRODUCTION

With two world wars and numerous regional wars and internal armed conflicts, the twentieth century witnessed unprecedented human misery, deprivation, displacement of people, economic disaster and increased poverty. In Europe and Japan, the loss of several millions of youth created a serious imbalance in the work force. As the dependency ratio (an indicator of the age composition of the active vs. the ageing population) increased, Western countries encouraged massive immigration of an active labour force from the developing world. By the mid-1960s and 1970s, however, the increase in agricultural productivity, the improvement of transportation, the development of national political stability, social and economic change, and the extraordinary achievements of science and technology ushered in a period of economic and social consolidation. Resulting improvements in nutrition and health care increased the life expectancy and decreased the death rate throughout the world. Simultaneously, progress in education, improvements in the position of women, as well as factors such as modernization, increasing family cost, urbanization and industrialization, dramatically reduced fertility. The world faced a spectacular increase in the 'third age' or senior population. Ageing and the elderly became matters of universal concern.

Three specific areas regarding older persons are dealt with in this chapter: ageing as a global social phenomenon; older persons and value systems; a new perspective of the international community.

### A GLOBAL SOCIAL PHENOMENON

In 1950, there were 200 million people over the age of 60 in the world. By 1975, the number had increased to 350 million, and reached 600 million in 2002. Today, one out of every ten people is over sixty. The rapid growth of the older generations had significant consequences in economic, social, cultural and political spheres. The older generations proliferated both in the poorest as well as the richest countries of the planet, but not evenly. One out of every five Europeans, in comparison to one out of every twenty Africans, is at least 60 years old. One million men and women reach the age of 60 every month, and 80 per cent are from developing nations. Approximately 53 per cent live in Asia, 25 per cent in Europe and 22 per cent in the rest of the world. Japan has recorded phenomenal growth. In general, 55 per cent of the aged population are women. Moreover, 65 per cent of the oldest segment of the senior population are women.[1] In industrialized countries, 74 per cent of ageing people live in urban areas, while in developing countries the majority live in villages or remote areas with only 37 per cent in urban areas. One per cent of the total human population is over 80 years of age. Recent United Nations research reveals that six countries – China, United States, India, Japan, Germany, and the Russian Federation – account for 54 per cent of the total number of those aged 80 years or over.[2] The third category of the ageing populations, i.e., people over 101 years, also registered an overall increase. The quality of life of older persons has deteriorated in many parts of the world over the past 15 years. This situation is worse in the developing countries. Several millions of elderly people lack economic and social support to afford their basic human needs. The majority of elderly people live below the poverty level. Many have been excluded from society and neglected by their families. Beginning in the 1950s, the age structure of industrialized countries became younger, and the substantial decline in fertility reversed the trend of population growth. Public policies aimed to increase the birth rate have failed to bring about marked change. The dependency rate has increased to a considerable level. The member countries of the OECD (Organisation for Economic Co-operation and Development) as well as other European countries provide elderly people with substantial advantages and services after retirement. These include pension benefits, social security, health care and housing. Yet elderly people in these countries suffer from psychological problems resulting from isolation and lack of emotional support from their families. The number of suicides committed by elderly persons seems to be higher than in developing countries. Newly industrialized countries and areas such as Hong Kong, Singapore, the Republic of Korea and Taiwan, parts of Latin America and

the Caribbean region, and the oil exporting nations such as the United Arab Emirates, Kuwait, Saudi Arabia and Libyan Arab Jamahiriya have witnessed a considerable increase in the ageing population.[3] In many respects, the situation is similar to that of industrialized countries. Life expectancy has increased as a result of modern services, health care and other support systems. In such countries, economic support from pension benefits, provident funds and other social security programmes is available to only a very small proportion of the older population. Yet the elderly still have to contribute to their families by way of babysitting and housekeeping, while the younger generation goes to work. Such tasks carried out by older people are not considered to be of any economic value, but the older generations are nonetheless regarded as an asset to the family.

The situation of elderly people in developing countries is considerably worse than in developed regions. As no pension or social security benefits are available to them, despite their long involvement in agricultural production, older persons often become a burden to their families. However, increasing urbanization and inter-migration have changed traditional family life. As young married women and men migrate to urban areas for employment, the elderly parents are compelled to live alone with no one to care for them. Conditions vary in different cultures. In spite of rapid modernization in Latin American countries, the family relationship with elderly people still remains very strong, even though contact between different generations in the same household leads to a low level of satisfaction for the elderly.[4] In Asia, India is unique in that the joint family system wherein families of male children continue to live with the aged parents, treating the father as patriarch, enables the elderly parents to exercise control over family resources. The newly independent countries, especially those of the former Soviet Union, encounter considerable problems in matters related to the economy, social welfare, politics, inflation, immigration and population, including a rapid increase in the number of older persons. In such situations of transition, job seekers move from rural areas to large urban centres. Many others immigrate to developed countries, legally or illegally, to find economic security in order to help their families, including older parents.[5] This internal and external migration has created considerable problems as regards accommodation and other facilities especially in main cities. More older people in transition countries live with their families, than those from industrialized countries. Yet they also encounter problems of loneliness, abandonment and dissatisfaction with economic conditions. They also have very limited access to social security and other benefits of social well-being. Unprecedented longevity is a sign of prosperity of world nations. It has repercussions, however, firstly as regards economic growth, savings, investment and labour force, secondly, social affairs, and thirdly, political affairs such as migration and refugee problems. Ageing populations constitute a burden on the active labour force. According to the International Labour Organization (ILO), the ageing labour force's participation rate is much higher in developing countries of Asia, Africa, and Latin America and the Caribbean than in the developed countries of Europe and North America. The decline in participation affects national per capita income, while increasing expenditure on social security and other social benefits. In developed countries, people spend a longer period in education, begin their professional careers later in life, work for a shorter time and receive retirement benefits for a longer period. The main economic and social implications of an ageing population are the burdens of economic dependency and the non-recognition of its potential as a resource for development. The twentieth century has witnessed a marked improvement in mobilizing the elderly people as a social asset.

The experience of ancient cultures in which the ageing population had a significant educational, cultural and spiritual role to play in society has been evaluated in a favourable light. Many societies have also clearly recognized the desirable involvement of grandparents in early childhood care and education, thus relieving the economically active parents to pursue productive enterprises. Such a transformation of roles has been advocated not merely for economic effectiveness but also for the invaluable ethical and spiritual considerations in favour of transgenerational transmission of wisdom and values. If one wishes to call the twentieth century the era of the recognition of older generations, it is because of the awareness of the important role that the elderly population can play in overall social development. In traditional society, the family, recognized as a basic social unit, lived together, and was composed of grandparents, parents, children, grandchildren and great-grandchildren. The members of the family maintained respect, duties, and obedience towards elders. The ties between the old and new generations constituted the cement that held the social edifice together. Like other faiths, Buddhism teaches us that 'for one who frequently honours and respects elders, four worldly rewards (age, beauty, happiness and strength) increase'. Chinese culture – influenced by Confucianism, Taoism and Buddhism – assigns a position of great veneration to the elderly (Plate 61). In the third century BC, the preservation of ethical, cultural, and religious values and respecting aged people was highly praised by the Buddhist Emperor Asoka of India. The Edicts of Asoka highlight the duties of children towards their parents. For example, Rock Edict (Girnar) III states: 'meritorious is obedience to mother and father', (*sādhu mātari ca pitari ca sūsūsa*), and Edict XIII advises: 'develop obedience to elders' (*gurunā suśrusā*). The *Aguttaranikāya* records that families in which the parents are highly respected deserve approval; such families are declared to be of the Brahman rank *sabrahmakāni*, together with the early great teachers, *sapubbacariyakāni*, and worthy of offerings (*āhuneyya*). In recent times, due to modernism, globalization, urbanization and immigration, family ethics have deteriorated, resulting in an inevitable generation gap between the old and younger generations. Throughout the world, there is a growing awareness that the ancient value systems, which promote the mobilization of the ageing population into active participation, should be revived in society.

## OLDER GENERATIONS AND VALUE SYSTEMS

Elderly people have been honoured by generations as transmitters of a universal cultural heritage for the benefit of humanity in the form of popular and traditional expression, performance, language, customs, music, ritual and traditional knowledge, art, craftwork and wisdom

(Plate 62). Deference to elders is in many instances attributed not only to respect for old age, but also for recognition of their valuable accomplishment in preserving different cultural values and experiences over the centuries. Conscious efforts have been made to preserve the knowledge and skills transmitted by the elderly. In the latter part of the twentieth century, UNESCO launched an important programme pertaining to the study and recording of the so-called intangible heritage in countries with deeply rooted oral traditions. The stirring and often-used quote 'when an old man dies an entire library is lost forever' effectively illustrated the importance of such activities.

Older generations of the Semeiskie people in the Transbaikal region of Russia, for example, possess a cultural tradition derived from a pre-seventeenth-century orthodox cult. The Semeiskie culture maintains moral principles, traditional dress, songs and traditional oral practices with the direct involvement of the elderly population. In Africa, there are many ethnic communities that have preserved extremely important cultural activities. In Benin a well-known performance called Gelede by the Yoruba-nago and other communities has been revived and takes place every year just after the harvest season and during droughts and epidemics. The Gelede performance combines the use of masks and songs in native languages, to recall the myths and the history of the Yoruba-nago culture and its people. The awareness of the role of the older generations contributed to its revival.

The well-known *Nātya Sāstra* of India, which has been transmitted by older generations over many centuries, is a vehicle of incomparable cultural, social, educational and religious values. The *Rāma Līlā*, a famous classical drama, is annually performed in practically every village in northern India. Elderly people preserve the tradition. The same is true of the *Kutiyattam*, a Sanskrit drama performed in Kerala in southern India.

In Ecuador and Peru, the Zápara people have developed an oral culture that reflects a particularly rich understanding of their natural environment. This distinctive cultural tradition is expressed through their cosmology and mythology as well as their rituals, artistic practices and language.

The Korean Royal Ancestral Rite represents an outstanding component of the world's cultural diversity. During the performance of this cultural and ritual practice, an important place is given to songs, dance, and traditional ritual music.

The Mystery Play of Elche in Spain is a sacred musical drama that commemorates the death, the assumption and the crowning of the Virgin Mary. This unique religious celebration from the mid-fifteenth century offers living testimony to the religious performances of the Middle Ages in Europe and to a Christian cult of extraordinary cultural value.

The Kandy Perahara in Sri Lanka recalls the island's 2,000-year-old Buddhist and Hindu cultural heritage. This celebration is a unique pageant in which several hundred elephants and thousands of traditional dancers participate and showcase Sri Lankan artistic heritage. In all these cultural activities, older generations, with leisure to pursue cultural activities, have acted as the principal proponents and promoters. The twentieth century has also seen the recognition of the role of the elderly in the preservation and transmission of indigenous knowledge, safeguarded by our

ancestors for the benefit of humanity. Apart from ethical and religious lore, such knowledge includes hitherto unrecorded information on medicine, forgotten technologies and many other kinds of know-how. As custodians of such rare knowledge and skills, elderly people have made significant contributions. The older generations have also played an important role in the evolution of social values in the process of transformation from traditional to modern societies. The experience, knowledge and guidance of older people have always been great assets in this process. Their indisputable authority has been exercised in the traditional family structure, especially in Asia, Africa and some other countries as regards important internal and external family affairs. They have been respected by the family members for their wise guidance. Moreover, the elderly have always participated in religious, cultural or social celebrations as guests of honour and they continue to play an important role as leaders in communal life. As those who attempted to foster modern development have realized, no progress in modernization could be made without the participation of the older generations. This factor largely accounts for the success of many development initiatives in Asia, Africa and Latin America.

## A NEW PERSPECTIVE OF THE INTERNATIONAL COMMUNITY

The international community has been in the forefront in raising awareness of the importance of older generations. In 1948, as the first step, the United Nations General Assembly adopted a resolution concerning a draft declaration on the rights and position of older persons. In December 1969, the General Assembly included in the Universal Declaration of Human Rights the need to protect and assure the rights and social welfare of the aged. In 1973, the United Nations General Assembly adopted Resolution 3137 (XXVIII) entitled: 'Questions of the elderly and the aged'. On this occasion, the subject was studied by the United Nations specialized agencies, in particular by ILO, WHO, UNESCO and the United Nations Food and Agricultural Organization (FAO). In 1974, the World Population Plan of Action adopted by the World Population Conference urged member states to take into account the problem of the aged in elaborating their national development policies. In 1977, the United Nations Economic and Social Council and the General Assembly dealt with the subject of the elderly, and a resolution was adopted inviting the member states to a 'World Assembly on Ageing'. One year later, in the course of the thirty-third session of the General Assembly, Resolution 33/52 of 14 December 1978 paved the way for the Vienna World Assembly on Ageing in 1982. This very successful convention launched an International Action Plan aiming at creating opportunities for the elderly in the fields of economics, culture, education, health care and security. The Vienna Plan of Action contributed to making member states aware of the challenges and issues related to the elderly and demonstrated the international community's commitment to the ageing problem: 'The Plan of Action should … be considered an integral component of the major international, regional and national strategies and programmes formulated in response to important world problems and needs. Its primary aims are to strengthen the capacities of countries to deal effectively

with the ageing of their populations and with the special concerns and needs of their elderly, and to promote an appropriate international response to the issues of ageing through action for the establishment of the new international economic order and increased international technical co-operation, particularly among the developing countries themselves'.[6]

Since the Vienna Convention, the world has seen a dramatic change for the better in national programmes for elderly people. In 2002, on the occasion of the twentieth anniversary of the Vienna Plan of Action, the second Convention on Ageing in Madrid adopted a new International Plan of Action on Ageing. After a very successful five-day convention, the member states agreed on a political declaration comprising 17 articles. The commitment of the member states on the ageing problem is stated as follows: 'We, the representatives of Governments meeting at this second World Assembly on Ageing in Madrid, Spain, have decided to adopt an International Plan of Action on Ageing 2002, to respond to the opportunities and challenges of population ageing in the twenty-first century and promote the development of a society for all ages. In the context of this Plan of Action, we are committed to actions at all levels, including national and international levels, on three priority directions: older persons and development; advancing health and well-being into old age; and, ensuring enabling and supportive environments'.[7] The International Plan of Action on Ageing in 2002 reiterates the need for Member States to change policies, attitudes and practices regarding ageing in their respective countries in all sectors to enable older persons to contribute to development and to participate within their families and communities in a respectful and secure environment. It is hoped that the implementation of these decisions will result in meeting all challenges of the older generations and establishing a society where older persons are enabled to age with dignity and participate in development activities as full citizens at the dawn of the new millennium.

## CONCLUSION

The ageing generations occupy a considerable place in modern society and government and international agencies. They are engaged in politics, interacting in the globalization of education, culture, communication, technology and the economy. The increasing dependency ratio would appear to contribute to the perception of the elderly as a burden to the working society. Since 1982, the situation has begun to change in a positive way. Governments and people in general have become increasingly aware of elderly people as a social asset. Their knowledge and experience are recognized as potentially valuable towards developing various activities. The situation still remains unsatisfactory in the developing and the least-developed countries as related to health care, food and lodging, security and maintaining a minimum level of dignity for elderly people. The rapid ageing of the world population encounters two powerful forces: globalization and urbanization. Older persons live longer and leave the working place earlier. Their accumulating knowledge and practical experience may not fully contribute to development activities. As emphasized by the United Nations catch phrase 'a society for all ages', older persons could contribute to society as mentors, advisors, teachers and creators. On the other hand, lifelong education will facilitate the creation of a dynamic society, which could benefit, support and maintain a positive social order, promote productivity and enhance a society for all without discrimination on the basis of one's age.

## PEOPLE WITH DISABILITIES

*Seamus Hegarty*

### INTRODUCTION

In the sweep of history, the twentieth century will stand out as a time when people with disabilities began to come into their own. It was increasingly recognized that society had a civic responsibility to people with disabilities, as to any other disadvantaged group. Provision of all sorts – education, medicine, rehabilitation, housing and employment – was elaborated, in many cases for the first time. While there is still much to achieve, and access to ordinary social goods is extremely uneven, people with disabilities have progressed from a situation of widespread marginalization to one in which their rights to social goods are at least acknowledged. Moreover, in some countries, considerable help is available to enable them to live as full members of their communities.

Despite the progress made, significant problems persist. These fall into two broad groups: limited availability of provision, and the inappropriateness of some of it. In developing countries and in rural communities more generally, many people with disabilities who could benefit from support do not receive it. This can be explained by a lack of technical resources or expert staff or by the fact that services originally developed in a technocratic, urban context have failed to adapt to markedly different situations in other communities. The second set of problems derives from the inappropriateness of some models of provision and, in particular, their failure either to respect individuals' autonomy or to challenge segregative attitudes and social arrangements.

Estimates of the number of people with disabilities at a given time are complicated by problems of definition and limitations in the available statistics. Whether or not an individual is regarded as disabled depends on attitudes to individual differences, the extent to which structured definitions are in use and the availability of provision. The collection of statistics on disability is extremely variable and is based on different category systems.

E. Helander reviewed the available statistics and concluded that the global average for the prevalence of moderate and severe disability was about 5.2 per cent.[1] Estimates across countries varied from 0.2 per cent to 21 per cent, illustrating the difficulty in obtaining sound statistics.

It is clear, however, that the number of people with disabilities worldwide is extremely large.

### SOCIETAL ATTITUDES AND PROVISION

The history of societal attitudes to people with disabilities, and of the resulting provision, can be schematized in five stages: rejection, neglect, care, elaboration of provision, and inclusion. This schema is not intended to offer a precise, linear account; the stages overlap and are manifested in different ways according to the countries. Its purpose is rather to provide an explanatory framework for a diverse set of phenomena.

#### Rejection

In ancient Sparta, deformed infants were left to die of exposure. Other societies too have sanctioned the killing of children who were perceived as imposing an excessive burden on the community. This ultimate rejection had generally disappeared by the beginning of the twentieth century, but people with disabilities experienced – and continue to experience – rejection in a variety of other ways, ranging from social rejection to the denial of legal rights. Within disability politics, there is a radical viewpoint that certain medical interventions such as amniocentesis (a process that screens for abnormalities in the developing fetus) and cochlear implants (surgically inserted electronic devises that restore some sound to totally deaf persons) constitute a rejection of disability; amniocentesis, because it is used to identify and abort damaged fetuses, and implants because they devalue and even threaten the existence of natural sign languages.

#### Neglect

Education and social services have advanced through the twentieth century, in terms of both sophistication and

coverage. However, those with disabilities have regularly been ignored in these developments or have had services extended to them much later than their peers. As access to schooling spread, for instance, children with disabilities were often overlooked, and in many countries they were considered ineducable. Where education was provided, the ministry of education was often not involved; educational arrangements for these children were routinely entrusted to ministries devoted to health or social affairs (this situation has changed in recent years; most, though by no means all, countries now manage education for all children and young people within a single administrative framework). Similar neglect can be seen in relation to employment, housing and leisure: people with disabilities were widely ignored or marginalized in these essential areas of human experience.

## Care

Early improvements in the condition of the disabled arose from benevolence, whether fed by humanitarian concern, religious belief, or direct contact with people with disabilities. The centuries-old tradition of caring for the disadvantaged was extended intermittently from the eighteenth century to the disabled. Charitable initiatives initially led to schools for the blind and the deaf, followed, during the nineteenth and early-twentieth centuries, by schools and other institutions for children and adults with a variety of disabilities. Many institutions for adults with a mental handicap had little or no orientation to human development, and residents lived very restricted lives. Humanitarian concern remains a potent stimulus for educational, employment and rehabilitation initiatives concerning people with disabilities. Making adequate provision for the disabled entails additional costs, and very often the required resources are funded by voluntary bodies, charitable foundations or aid agencies (Plate 63).

While some outstanding provision has been established in this way, its origins in benevolence define people with disabilities as objects of kindness rather than recipients of entitlements. A more radical critique construes benevolence as a form of social control and highlights the negative features of provision associated with it. Thus, institutional provision is seen to serve professionals' self-interest and society's economic concerns rather than clients' well-being.

## Elaboration of provision

The outstanding feature of the twentieth century as regards people with disabilities was the elaboration of provision and specialist services. These developments drew from a wide range of sources: a general expansion in medical and social services, new understanding of disabilities, campaigning by pressure groups, research inputs, technical advances, increased prosperity, and legislation. Progress was uneven across and within countries, and developing countries had only a limited share in it, but the achievement was nonetheless significant (Plate 64).

Developments in education, a critical determinant of an individual's chances in life, included extending schooling to many previously excluded from it, targeting teaching approaches on individual need, reforming regular schools so that they provided appropriate, high-quality education for many more pupils and devising vocational training that

took into account individuals' capacities as well as job requirements. Rehabilitation services developed especially in the second half of the century, driven by medical and surgical advances and drawing on rehabilitation techniques developed for war-wounded people. As a result, people with disabilities in some countries have access to a range of medical interventions and therapy services and are better equipped both for employment and daily living.

A significant factor in the above-mentioned developments was the acknowledgement of the rights of individuals, as reflected in much national legislation but also in international declarations. Two important United Nations instruments – the Universal Declaration of Human Rights (1948) and the Declaration of the Rights of Disabled Persons (1975) – represented important symbolic steps. More concrete action followed from the International Year of Disabled People proclaimed by the United Nations in 1981, which marked a turning point in promoting issues relating to disability. This initiative stimulated activities within United Nations agencies, such as the International Labour Organisation and UNESCO, as well as at the regional level (the European Community) and national levels. In particular, it led to the United Nations World Programme of Action concerning Disabled Persons in 1982, and the subsequent Decade of Disabled Persons (1983–1992). In 1993, the United Nations adopted the Standard Rules on the Equalization of Opportunities for Persons with Disabilities, which urge governments to take the necessary steps to make systems and social structures accessible to people with disabilities.

## Inclusion

Towards the end of the twentieth century, the inadequacy of provision based on either benevolence or technocratic expertise began to be recognized. Several brands of social ideology fed into this: the Scandinavian belief that people with disabilities should live as normal a life as possible; the notion, elaborated by the anti-psychiatry movement in Italy, that large institutions provided an unsatisfactory living environment; the insistence on the civil rights of the disabled prevalent in the United States; and the growing demands for self-advocacy, whereby people with disabilities are expected to have a significant say on all matters affecting them. These developments were associated with a radical critique of existing provision which, when not marginalizing people with disabilities, was seen as reinforcing their minority status.

In the classroom, these developments led to a movement away from mainstreaming and towards inclusion. From the 1970s onward, a great deal of campaigning, research and innovation had centred on mainstreaming or integration in the sense of placing pupils with disabilities or learning difficulties in regular schools. While this led to more appropriate education in many instances, it was not enough, and more radical changes in regular schools were sought. These entailed creating new kinds of school that were defined and resourced in terms of meeting the particular needs of every pupil as an integral part of the school's provision, regardless of the individual pupil's disabilities or learning difficulties.

Community-based rehabilitation also challenges traditional models of practice with their excessive reliance on institutions and specialist expertise. People with

disabilities come from families, and the goal must be to locate rehabilitation measures within their families and the communities. This approach does not to reject expertise but recommends that it be deployed at the local level so that people with disabilities can live unrestricted lives within their communities.

These are examples of the general demand for people with disabilities to be included in everyday life and for action to focus on removing the social and institutional barriers that prevent integration. Given that these barriers exist in society and its segregative institutions and not in individuals with disabilities, action should be directed to the former rather than the latter. By the close of the century, these views were gaining ground but were far from widespread. There was a great deal of rhetoric in their favour, but much provision continued to be couched in terms of enabling people with disabilities to fit into society rather than reshaping social institutions so that they included all people, regardless of their disabilities.

## CONCLUSION

The twentieth century has seen major advances in the understanding of disability issues, in the legal status ascribed to people with disabilities, and in the range and sophistication of provision available to them. However, these advances are spread unevenly. While the situation of some people with disabilities has improved greatly, many others, particularly in developing countries, continue to be marginalized in their societies and to live extremely impoverished lives.

The challenge for the years ahead is twofold: to extend the best of current provision, and to ensure that people with disabilities can participate in decisions that affect them. Many people with disabilities continue to be neglected and marginalized in their societies. Improvement will come partly from obtaining more resources and deploying available resources more effectively, partly from securing commitment to action from governments and social institutions, and partly from changing attitudes ensure that people with disabilities are regarded as full members of their communities. All of this must be accomplished in a suitable context, that is, one in which the voice of the disabled is heard, the disabled set the agenda and shape decisions that affect them, and disability is seen as part of the normal pattern of differences between people.

# TRADITIONAL SCIENCE AND KNOWLEDGE IN EAST AFRICA

*Judith Mbula Bahemuka* and *Wellington N. Ekaya*

## INTRODUCTION

In Africa, the potential role of traditional knowledge systems in the arena of sustainable development began gaining prominence in the 1970s. Scholars started voicing concern over the failure of development efforts to improve the living standards of local communities, thus underlining the need to review development strategies and alternatives. The major focus was placed on the advancement of indigenous peoples in the context of prevailing physical conditions. More specifically, the idea of preserving the indigenous communities' resource base, while at the same time incorporating their knowledge within planned development packages, became imperative and topical. Thus, identification of local constraints and viable development efforts responsive to the social and environmental impacts of change required assessment.

Within this context, it must be noted that local ideological and institutional structures are important springboards acting to minimize the adverse effects of development packages. The underlying logic is that local people have their own ways of sustaining their own development. It follows that any development effort will fail if it is culturally offensive, socially insensitive, and ecologically incongruent with local knowledge.

The principle underpinning traditional knowledge and science is that between the physical environment and human activities there is always a mediating factor, a collection of specific objectives and values, and a body of knowledge and beliefs constituting the dominant cultural patterns. This knowledge is specific to certain societies and localities. It is created by one generation and passed on to succeeding generations through socialization. Traditional knowledge and science therefore constitutes an important component of culture. Culture itself is subject to change, but communities tend to cling to certain cultural elements, which generally persist even amidst sweeping changes. Early studies of African traditional knowledge systems were conducted on agricultural practices, for example among the Sandawe and Nyiha of the United Republic of Tanzania (Plate 65). Contemporary studies in traditional knowledge systems aim at adapting modern innovations to local

knowledge in order to induce change. This recognition of the variation in cultural approaches to resources ensures sustainable development.

This chapter deals with traditional technical knowledge within the East African region. It draws examples from some of the ethnic communities which have developed the art of herbal medicine and sustainable livelihoods through traditional irrigation systems for small-scale farming.

The term *traditional knowledge* conceptually brings into sharp focus and underscores the originality of the knowledge as perceived and practised by communities in a specific locale. The term *knowledge* as used in this context refers to collective perceptions, traditions, lore, and other associated knowledge and practices, whether intentional or unintended. Traditional knowledge consists of a large body of collective perceptions, traditions, lore, and practices generated by rural communities over time for various purposes. It is unique to a culture or society and believed to be consistent with coherent sets of cognitive techniques. It has been variously known as indigenous knowledge, traditional wisdom, indigenous technical knowledge, traditional knowledge, and community knowledge. This system of knowledge includes concepts, beliefs, perceptions, the stock of knowledge and the processes through which it is acquired, enriched, stored and transmitted. Traditional knowledge develops over generations as a product of human–environmental system interactions. Through indigenous creativity and innovation, traditional knowledge remains dynamic and often borrows from other knowledge systems through contact.

Ethnoscientists do not agree with the assumption that society can live in ambiguous and non-defined relationships with its socio-cultural, physical, and technical environment. This position is clearly defined by works of different scholars from several perspectives. On the one hand, learning can take place only when an individual wants something (value-aspirational base) or notices something (awareness governed by selective perception derived from existing knowledge). On the other hand, human beings are constantly defining their environment so as to derive meaning and a format for action. These two arguments can be taken to imply that communities are constantly reviewing and arranging all

signals emanating from the environment to present a unified definition of the situation. It is this act of defining each situation that gives communities a frame of reference for decision-making.

The work of ethnoscientists can be evaluated in light of earlier arguments on learning theory. In the works of McClelland, there is a fundamental assumption that learning and evaluation of new ideas and technologies are related to existing and accepted arrangement of relationships, ideas and technologies. Traditional knowledge acts as the catalyst, which influences modern scientific innovations, partly by communication, interaction or environmental stress.

In spite of the differences in terminology used by different communities, societies and professions, there is evidence that ethnic communities possess immense knowledge of the systems in which they live, together with the system components with which they come into contact. Furthermore, they have developed effective ways of utilizing the knowledge to sustainably and wisely interact with their total space.

Traditional knowledge is passed from one generation to another by word of mouth through an elaborate system. This education technology is codified in the language structure and social interactions between members of the ethnic group. This kind of structure leads to a shared knowledge, a kind of science.

In essence, traditional knowledge is interactively derived and embedded in the cultures of communities. It is adaptable, appropriate, and technical (the technical side being embedded in its practical nature and capacity) so as to provide sustainable utilities. It is therefore a practical type of knowledge based on intimate experience accumulated over many generations. This ultimately forms the core of the process of community development.

## TRADITIONAL KNOWLEDGE

Traditional knowledge possesses a number of unique distinguishing properties:

a) It is generated within specific communities wherein it forms the basis for, *inter alia*, decision-making and livelihood strategies.

b) It is location – and culture – specific but allows for some degree of overlap due to contact between communities or cultures.

c) It concerns critical issues related to humans, their environment and resource management.

d) It is oral in nature and not systematically documented.

e) It is dynamic and based on innovation, adaptation and experimentation.

Prior to the general awareness of the value of traditional knowledge, certain practices were considered to be associated with superstition and witchcraft. Within the past quarter of a century, the applicability and usefulness of traditional knowledge has been gradually recognized by professionals and practitioners in various fields. Traditional knowledge is less expensive, readily available, environmentally sound, and most importantly, it has a proven record of effectiveness. However, professionals are

often unfamiliar with such knowledge owing to its oral nature. It appears clear that the use of such knowledge to foster sustainable natural resource management and development is vital.

## Traditional knowledge and science in sustainable development

Natural resource management in African pastoral systems has tended to emphasize the international scientific value of resource conservation and biological diversity, which has dictated the 'what, where and how' in relation to conservation efforts in Africa. For instance, IUCN (International Union for Conservation of Nature) noted that many biodiversity conservation strategies have failed to effectively address African values, priorities and practices. Africa's dependence on biological resources for economic and natural purposes has not been given adequate recognition.

For a long time, there has been some antagonism between the wide range of traditional resource management systems practised by African farmers and the conventional or mainstream range management, which has been advocated by development institutions, academicians and modern society in general. On the one hand, conventional range management dismisses traditional resource systems as primitive, self-destructive, and thus too unproductive to provide goods for the increasing human demands. It has since imposed its de facto authority in matters pertaining to pastoral development. On the other hand, farmers have interacted and, at times, accepted – albeit with suspicion – this approach to survival and development that often conflicts with tradition and culture. This accounts for the numerous failures characteristic of development interventions in rural Africa.

Debate on sustainable development stresses the importance of harmonizing traditional knowledge and Western science. *Agenda 21*, a comprehensive plan of action adopted by the United Nations at the 1992 Rio Summit, for example, notes that governments should provide local communities and resource users with the information and know-how they need to manage their environment and resources sustainably, applying traditional and indigenous knowledge and approaches when appropriate (Plate 66). However, the challenge consists of determining the manner in which such integration can be achieved, considering the differences between the two epistemologies. A general overview of the two systems of knowledge is presented in Table 1.

From the foregoing discussion, it is clear that traditional knowledge can be used to complement modern science. The following two examples are derived from the experiences of communities in East Africa.

### Case study: range management among the Masai of East Africa

Conventional range management is a multidisciplinary field bringing together scientists in biological sciences, social sciences and policy-makers. It depends on basic sciences, concerns grazing animals and forage in uncultivated lands in sub-humid, semi-arid and arid regions and focuses on the production of animal products, water, timber, wildlife and recreation that are useful to humankind.

*Table 1* **Traditional ecological knowledge and Western science**

| Traditional Ecological Knowledge | Western Science |
| --- | --- |
| Oral tradition | Written tradition |
| Learned through observation and hands-on experience | Taught and learned (abstracted from the applied context) |
| Holistic approach | Reductionist |
| Intuitive mode of thinking | Analytic and abstract reasoning |
| Mainly qualitative | Mainly quantitative |
| Data generated by resource users | Data collected by specialists and experts (exclusive) |
| Diachronic data (long-time series on one location) | Synchronic data (short-time series over a large area) |
| Environment as part of social and spiritual relations | Hierarchical and compartmentalized organization |
| Based on cumulative, collective experience | Based on general laws and theories |

Adapted from Johnson, 1992.

Unlike the mainstream range management, traditional pastoral resource management is based entirely on traditional knowledge that has evolved over generations as a product of man-environment interactions. Like other sciences, ethnoscience has a variety of knowledge systems to deal with biological and physical environments (indigenous climatology and weather forecast, botany, medicine, conservation, etc.), with cognitive and ideational environments (value systems), and others that deal with the social environment. In essence, local knowledge differs from modern scientific knowledge in that it allows a greater understanding of the heterogeneity of local conditions as opposed to scientific knowledge, which may be developed into universal generalization for a wide range of situations. The exploitation of indigenous plants and animals using rudimentary technology requires knowledge of the local ecological conditions.

Despite the apparent differences and dissimilarities between the two systems of resource management as conceived and practised for a long time in the African pastoral system, there are a number of unrecognized or ignored similarities that can be combined to improve and strengthen pastoral development.

All along, development agencies have designed and implemented livestock production rather than pastoral development in Africa. This misinterpretation of pastoral development has its genesis in the background of the development agents responsible for the design and implementation of pastoral projects, especially following the Sahelian droughts of the 1970s. Firstly, these development technicians were either from Europe or North America, where livestock production and conventional range management originated and evolved. Secondly, their African counterparts, who were largely educated in the West, tried to replicate their learning experience in their home countries. Thirdly, the successes recorded in animal production in these countries have enticed African policy-makers to readily accept the implementation of livestock development in pastoral Africa.

Commercial livestock production as practised in Europe and North America is primarily intended to increase beef production. The economic objectives of commercial beef production emphasize such parameters as optimum stocking rate and carrying capacity, weight gain, weaning weight and meat off-take in order to maximize livestock production per head. It is capital intensive in practice and confined in space. Livestock production is first and foremost geared towards the improvement of livestock and livestock products and their availability for market consumption. Its application in rural areas, as exemplified by group ranches across Africa, translated into the establishment of production units complete with disease control, water development, extension and marketing services to supply the larger domestic economy, increased off-take of pastoral animals for fattening and the strengthening of and support to livestock marketing services.

Livestock production programmes failed in pastoral Africa primarily because they took narrow conceptual and technical approaches to pastoralism, which wrongly equated livestock production and pastoral development. The programmes focused on animals and range lands rather than herders, people and institutions, thereby literally neglecting the social, cultural and ecological particularities of pastoral production systems. In addition, they failed to take into account the complexities and the development potentials and constraints of traditional pastoral organizations and production systems.

It has been stressed that pastoral development involves, in addition to livestock production, the recognition and genuine support of a pastoral entity within a wider national development programme. Pastoral development involves management of people. As such, it integrates anthropological aspects, cultural and sociological beliefs and practices of a people into a comprehensive development plan. This is in accordance with the nature of pastoral production systems where there is a strong interdependence between humans, livestock and land resources, leading to a true collaboration with nature rather than a control over nature, which is less painful and destructive.

Each culture has its own ethnomedicine, which is part of its indigenous knowledge. Knowledge of ethnomedicine provides insights into the diseases and the available medical care in a given community as a basis for considering contemporary health problems in that society. Every culture has its worldview, traditions, values and institutions, which have developed over time to handle disease and illness. Furthermore, each culture has its own disease aetiologies, medical terminologies and classification, medical practitioners and medicinal substances. Of course, a group's beliefs and response to disease and illness are hardly static; indeed, they change with time and as a result of interaction with the medical systems of other cultures. In this sense, the terms *traditional medicine* and *ethnomedicine* are somewhat misleading. The goal of the study of ethnomedicine is to understand how a society's system of medicine functions, to distinguish different types of systems, and arrive at theories concerning how these operate and change. All medical systems, including those with such labels as 'traditional' and 'ethno', are ever-changing, highly adaptable and adaptive. What appear to

differentiate medical systems are the key concepts and philosophical foundations of each system.

Traditional medicine is highly developed in Masai culture. It is based on the Masai's deep knowledge of ethnobotany (or ethnosystematics), that is, folk knowledge of botanical classification and the capacity to identify their natural environments. In traditional Masai society, herbal medicines were widely used for the treatment of both humans and livestock. Drugs are derived from trees and shrubs. The bark or roots are then mixed with water or fatty soup to make medicine, which is taken as soup, or mixed with milk, porridge, honey, blood and/or beer. Traditional Masai medicine is used to treat gonorrhoea, stomach upsets, throat infections, chest pains, dental problems, pregnancy disorders, infertility, eye diseases, fever, colds, swollen legs, painful joints, worms, and nervous disorders. It is also used to quench thirst and to give courage and strength, to treat anger or melancholy, and as a purgative or a poison.

Trees and shrubs hold ritual significance for the Masai. Only tree wood, bark and leaves may be used in 'purification' ceremonies to avert supernatural misfortune (Plate 67). The special ritual value of trees and shrubs is closely related to certain notions of Masai creation myths. The Masai believe that 'sky' and 'earth' were once one, and that it was only at the time of their separation and permanent division that rural Masai acquired their cattle, which, according to the various versions, were brought to them from *enkai* (which means 'God' and 'rain' as well as 'sky') via a rope made from the bark of a ficus tree, *Ficus natalensis*, or via a 'firestick' made from the same tree.

Perhaps the extensive Masai knowledge of ethnobotany is linked to these cosmological beliefs about their origins and their central economic resource, cattle. If so, this can help to explain the Masai repertoire of plant uses for myriad everyday tasks such as fodder for goats and medicine. But there are other reasons for the well-developed indigenous medical knowledge of the Masai, including the spatial and seasonal availability of pastures and water: the Masai's traditional migratory lifestyle forced them to inhabit multiple ecologic environments, varying from low to high altitude. On the face of it, these movements were intended to exploit resources, which were found at different places at different times of the year. The Maisai needed detailed local knowledge on the plants and grasses that grew in one place or another. This inventory of each habitat's flora had to be accompanied by their uses. Beyond this, the movements made it possible not to overuse any part of the range and so avoid the development of certain unpalatable grasses and the colonization of excellent grazing land by certain diseases and pests, especially ticks and the associated East Coast Fever. The spread of East Coast Fever is a function of the ecology of the tick vectors.

These conditions required that the Masai become skilled in epidemiology, that is, the spatial and temporal occurrence of diseases. This knowledge heavily influences the patterns of pastoralists' use and avoidance of certain areas until the signs of a disease dissipate. In addition, they would use medicinal plants both for prophylaxis and for treatment. The Masai are capable of making differential diagnosis of diseases such as foot-and-mouth, contagious bovine/caprine pleuropneumonia, malignant catarrhal fever, lumpy skin disease, anthrax and East Coast Fever. They base their diagnoses on the manifested symptoms and on indigenous knowledge of the diseases' course and known vectors.

Some traditional skills in the treatment and/or control of livestock diseases have been noted. For diseases like the East Coast Fever, the Masai's cauterize the inflamed lymphatic glands with a hot iron. The effectiveness of this 'cure' may depend on the mode of application. In addition, special herbal concoctions are used. The Masai are not entirely helpless in containing East Coast Fever.

The Masai withhold water from cattle that have contracted anthrax. Although it is not known exactly why this is done, experts speculate that withholding water from cattle in the semi-arid zone leads to an increase in body temperature and the delay of the onset of the disease. The virulence of *Bacillus anthraces* could be influenced by changes in temperature. A dramatic experiment by the famous chemist and microbiologist Louis Pasteur demonstrated that lowering the body temperature of fowl (chickens) by dipping the animal in ice-cold water increases the probability of its contracting anthrax. Due to their high body temperature, chickens are normally resistant to anthrax. Withholding water does not 'cure' the disease, but the Masai believe that it does give them enough time to trek long distances to buy the antibiotic.

The Masai have no effective cure for malignant catarrhal fever and other viral diseases. Through diagnostic skills however, they have known for centuries that the gnu (wildebeest) is a silent reservoir for this disease. This knowledge has enabled them to develop an elaborate disease control procedure involving strict separation of cattle from the gnu and avoidance of surface water as watering sources for the animals during the gnu-breeding season. Only recently did modern scientists realize that malignant catarrhal fever, which was described by an Egyptian nomadic cattle healer as early as 3600 BC, was transmitted to cattle by the gnu.

### Case study: The Perkerra irrigation scheme

The Perkerra River flows through the Koibatek District of Kenya. The traditional inhabitants of the area were the Ilchamus Masai, more widely known as the Njemps. In the nineteenth century the British explorer Joseph Thompson and his caravan reputedly stopped by the Perkerra to purchase grain from the Ilchamus. How did the local pastoral-oriented community manage to obtain grain? The answer can be found in the Masai's capacity to understand their environment. In order to survive, the community developed an elaborate irrigation system based on traditional water management and basin irrigation. They constructed rectangular-shaped basins, with an area of 6 to 9 sq. yards, that were flooded via an opening. Once the canal was full, the opening was sealed and another opening was made in the next row of canals. The Njemps community has maintained its knowledge of water use, control and distribution to the present day. This knowledge can be tapped to enable other communities to respond to their developmental needs.

### Challenges to indigenous knowledge

The spatial and ecological design of traditional Masai life provided a stable foundation for their economy and

welfare. Traditional medicine flourished. Occasionally, such as occurred in the late nineteenth century, the risks of drought and disease can overwhelm traditional arrangements, placing severely strains on their system of medicine. During such times, appropriate interventions using their know-how, in irrigation systems for example, become crucial.

British colonial intervention in the land of the Masai dealt a blow to traditional ecosystems. Large chunks of land around Lakes Naivasha, Elmenteita, Nakuru and Baringo in Kenya and the rivers flowing into them were adversely affected. Such lands were always crucial to the proper management of the Masai pastoral system by providing dry season herding resources. Native reserves were created in the drier areas of their territory.

As populations of livestock and humans increased, natural resource degradation set in. In Masai territory, there has been a dramatic reduction of vegetation diversity over the past several decades. The evidence for this includes the further colonization by the *Tarchonanthus camphorates* bush[1] and the destruction of forest vegetation and grassland, which began during the colonial period. This process has left occasional patches of trees and bushes. With this destruction, indigenous medicinal plants have disappeared, thereby affecting the supply of Masai traditional medecines and, with it, precious indigenous medical knowledge.

There is little systematic recording of this rapidly disappearing knowledge because the older members of the community have been the traditional repositories of this knowledge. Leading scholars have called for a thorough and systematic survey, collection, identification and proper documentation of medicinal herbs with a view to building a germ plasm collection. In order to do this, ethnomedical information is required to create proper standards for traditional medicine, thereby enabling its use in the general context of health care. Such information may be obtained from traditional medical practitioners, published literature and oral sources within the community concerned. The data will make it possible to extract natural drugs from plants and then isolate their known active ingredients. In the case of irrigation systems, the Njemps have demonstrated that traditional knowledge can be refined and augmented by modern science to provide communities with sustainable livelihoods. Such is one of the challenges facing scientists in the twenty-first century.

## MODERN SCIENCE AND CHANGING NOTIONS OF TIME, SPACE AND MATTER

*Michel Paty*, coordinator

in collaboration with *Michel Morange* and *Christian Houzel*

### INTRODUCTION

As the First World War was raging, providing yet more evidence of human folly, new scientific knowledge that would revolutionize our perception of the world was taking shape at a speed quite unprecedented in the history of humankind. This expanded vision would also revolutionize our perception of ourselves and our basic concepts of knowledge. Once the smoke from the epic confrontation finally cleared, the landscape that emerged was nearly unrecognizable, so great were the intellectual and scientific transformations affecting our understanding of the natural world.

The most ambitious and surprising change, which gave rise to heated debate and was a source of fascination for many, concerned the new vision of the physical world and the Universe. In May 1919, the astronomer Arthur Eddington led a scientific expedition commissioned by the Royal Society and the Royal Astronomical Society of London to the Gulf of Guinea and Brazil to observe a solar eclipse on the equator; the expedition was a symbol in itself. The challenge extended far beyond the bounds of astrophysics and knowledge of the Sun's corona and solar eruptions; indeed, the main purpose was to see if any curvature could be observed in light rays from stars as they passed close to the Sun. Any such observation would prove that space was bent by the large masses of matter it contained and thus support the general theory of relativity presented by Albert Einstein at the Berlin Academy of Sciences in late 1915.

Einstein's theory of relativity radically changed our physical notions of space and time, and with it the kind of intuitive assumptions about physics that had prevailed for more than two hundred years. Over the same period, *cosmology* almost literally brought the entire Universe within the scope of scientists, who were realizing how immense it was and would soon discover that it was expanding. The final years of the First World War had been decisive, paving the way for another, and perhaps even more radical, revolution. This concerned a new understanding of what constituted 'common' matter in its innermost structure: first the *atom*, then the *subatomic structure* that emerged during the 1930s and 1940s following the impact of *quantum physics*. Off in a quite different direction, during the 1930s a

number of scientists, working on the findings of Henri Poincaré, explored the mathematical theory of *dynamic systems*. This theory produced concepts of 'deterministic chaos', starting in the 1960s.

All other areas of science, and specifically other exact sciences or natural sciences, underwent considerable change during this period. The so-called formal sciences, such as the different branches of mathematics and logic, saw changes that brought into question their very foundations, while operational calculus and computer science were also beginning to emerge. Like physics and chemistry, the natural sciences, and especially biology, felt the aftershock of the quantum revolution, which altered interpretations of Darwin's theory of evolution, and gave rise to immunology and genetics and the biomolecular approach that would prevail in the 1950s. Neurophysiology, supported by the latest techniques of physics and chemistry, expanded greatly from the 1980s on, bringing with it the growth of cognitive sciences. In geology, pioneering work on continental drift begun by Alfred Wegener in 1912 was confirmed by the theory of plate tectonics. Although rejected at the time, these breakthroughs turned out, fifty years later, to totally alter our perception of the world. Wegener's findings were consistent with work in other disciplines (e.g. the evolution of the Universe, the 'life and death' of stars involving chemical elements and the evolution of life). These showed that constant change is the cosmic, physical and biological world, that matter and the Universe are one, and that all these processes are interconnected.

Thus new borderline sciences emerged and, like the shifting and thrusting of continental plates forged over thousands and millions of years, they too gave rise to new and different perspectives of the world we live in.

### NEW CONCEPTS OF MATTER, SPACE AND TIME

#### The theory of relativity

The theory of relativity was developed in two stages in the early twentieth century. The first stage, *special relativity*,

arose from the need to reconcile two well-established sciences: the mechanics of physical bodies and the dynamics of electromagnetic fields. By expressing the invariance of the laws of physics in uniform motion in a straight line (i.e. *inertia*), the concepts of space and time as defined and accepted since Newton had to be changed: they were no longer independent and absolute, but merely relative, as was the concept of *simultaneity* in the frame of reference of spatial coordinates and the time related to them. Their close relationship was then expressed as a new physico-mathematical concept: four-dimensional *space-time*. Mass is a form of energy, as expressed by the formula E=mc², which became famous when it was later tested and applied in nuclear reactions.

The second stage, the *general theory of relativity*, arose from two key considerations: the arbitrariness of physical invariance being restricted solely to inertial motions, suggesting it might be extended to the most general accelerated motions; and equal local acceleration of bodies in a gravitational field (Galileo's law of falling bodies) – stated by Einstein as a *principle of equivalence*, between a gravitational field and accelerated motion. The theory, as developed on these bases using the mathematical formalism of space-time and absolute differential calculus (tensor calculus), meant a new generalized theory of relativity of gravitation could be expressed producing the space-time structure for physical spaces that were no longer Euclidean, and for non-uniform times: in other words, the curvature of space is determined by the masses contained in it and the gravitational fields they generate.

These two stages in the theory of relativity were originally the work of Albert Einstein. He pursued a line of thought based on the idea of the invariance of the laws of physics in transformations due to relative movements, and, from that perspective, he criticized existing theories of physics. The special theory of relativity emerged (retrospectively) as a prelude to the general theory of relativity. The fundamental originality of the second theory, which developed solely in the brain of Albert Einstein, confirmed the clear idea already present in the first theory, making it more radical still. It was his idea to change the concepts of space and time and to endow them with *physical content* dictated by general properties of matter, such as those expressed in the statement of the *physical principles* of the theories.

## Special relativity

Certain aspects of special relativity had, however, already been explored in other studies preceding or concurrent with Einstein's research; the most prominent were by Hendrik A. Lorentz and Henri Poincaré, who had presented the properties of *electromagnetic dynamics*, formulating equations similar to Einstein's, yet working on quite different conceptual content. In their view, the formulae for transforming the coordinates of space and time (referred to by Poincaré as 'Lorentz's transformations') – which, they argued, were needed for electromagnetic dynamics – could still be reconciled with the concept of absolute physical space (the ether at rest) and absolute, physical time, consistent with Newton's classical mechanics.

Einstein's theory, published in 1905, originally covered the 'electrodynamics of moving bodies', a theory he tried to refashion so that it would fit the 'principle of relativity'. His

theory stated that laws of physical phenomena did not depend on the motion (i.e. in a straight line and uniform, or 'inertia') of the bodies which were the focus of these phenomena. To do this, Einstein actually embarked on a much wider change, going beyond the initial project and producing what is known as the *(special) theory of relativity*, stating an invariance condition (or more accurately, one of *covariance*, i.e. not linked to any specific dynamics, but required of *all dynamics*).[1]

It seemed to Einstein that the validity of the principle of relativity, used previously for mechanics, should be extended to optics and electromagnetism for both empirical and theoretical reasons. The empirical reasons were actually generalizations of the findings of experiments on groups of *proven phenomena* rather than isolated observations; they were related to optical and electromagnetic phenomena which remained unchanged in systems at rest or in relative motion: it was therefore impossible, for example, to extrapolate the absolute motion of the Earth in relation to the 'ether' (the medium assumed to transmit waves) on the basis of these findings. However, electromagnetic theory (as formulated by James Clerk Maxwell some decades earlier) used the reference system of the *ether*, assumed to be at rest in the absolute space of Newton's mechanics, making its role too important and skewing it in relation to the set of systems in uniform motion and in straight lines.

This skew was not consistent with the principle of relativity, which the phenomena seemed to fit in other respects. Einstein noted this contradiction and ascribed it to a fault in electromagnetic theory (which did not comply with the principle of relativity), and also to the inadequacy of mechanics, laying down definitions and general laws on motion and relating them to absolute space and time, independent of physical phenomena. Einstein went on to change these two interrelated theories, yet retaining their most fundamental properties as a universally valid principle of physics: the *principle of relativity* for mechanics and the principle of the *constant speed of light in a vacuum*[2] for electromagnetic theory. The two principles appeared to be incompatible: if the speed of light was constant in the ether (absolute rest), it had to be different in any system in motion with reference to it, and this was contrary to the conditions of the principle of relativity. Yet (as Einstein realized), the incompatibility arose from the implicit assumption that the speeds of the two motions (here, the speed of light and the speed of the frame of reference) were calculated according to Galileo's law of the addition of velocities.[3]

But this rule could and indeed had to be abandoned, provided a new definition could be given of the *velocity* parameter, i.e. the *distance* and *time interval* to which it is related, imposing on these the two principles of physics so as to give them a *physical value*. Einstein, working on ideas previously expounded by Ernst Mach and Poincaré, began by pondering simultaneity, which was absolute for instantaneous actions (in Newton's physics), but only relative (to a specific frame of reference and not to all) for actions propagated at a finite speed. A new definition of the physical concepts of space and time, i.e. concepts given in relationships with phenomena, would then follow. The shift from one point in space to another and from one instant in time to another requires consideration of physical phenomena (e.g. the transmission of a light signal) operating between these spaces and times, and applying the two principles chosen.

On the basis of these considerations Einstein directly deduced transformation formulae that allowed a shift from one system of coordinates and time to another system in relative motion (Lorentz's transformations), showing there was mutual dependency of the time and space coordinates. These formulae then led to a new (relativistic) law of the composition of velocities for the constant speed of light when combined with any other speed, thereby making it an absolute limit.[4] This also led to the symmetry of relative motions and the end of the choice of *ether* at rest as the frame of reference: the very idea of ether, seen as a sort of half-way medium between matter and space, then became redundant.

The special theory of relativity that arose from these considerations led to new kinetics that could be applied to all systems of physics regardless of their dynamics, and which complied with the dynamics of Newton's mechanics in the approximation of low velocities.[5] In relativistic kinetics, relative distances are shortened in the direction of the motion, and relative time intervals get longer. This relativity of time and space means that a body in rapid motion seems shorter when seen from a system at rest in relation to it, and that the ticking of clocks there is slower. Paul Langevin later used this idea in arguing his 'thought experiment' on two twins being reunited after a cosmic voyage and having different ages. The same reasoning applies to a short-lived particle in its own system,[6] produced in the upper atmosphere through the interaction of cosmic rays, and able to reach Earth before it disintegrates: its lifetime in the laboratory frame of reference is extended because of the high speed of its motion. Similarly, high-energy particles produced in accelerators have a longer life in the relative system at rest where they are detected. Such experiments were not conducted until a long time after the special theory of relativity was first propounded, but they provide a direct illustration of it. They are commonly used today and have helped physicists become familiar with these concepts, which they now intuitively take for granted.

The relationship between mass and energy is a consequence of new kinetics and applies to any element of matter. It is more apparent with high levels of energy or exchanges of energy, as with radioactive decay and nuclear reactions, but applies generally. It has even been observed over recent years in certain chemical reactions of elements high in the periodic table with high binding energy in the inner atomic layers.

The main part of Einstein's special theory of relativity is in these properties: they concern new 'kinetics', i.e. a new way of conceiving and formulating the general properties of the motion of bodies in space and time, and having effects restricting the form of dynamics, because of the requirement of *covariance*, i.e. the principle of relativity mathematically transcribed on the form of the quantities in the physical theory and its equations. Hermann Minkowski presented a mathematical theory of space-time soon after this, basing it directly on Einstein's special theory of relativity. He took the idea originally stated by Poincaré that time should be entered as a fourth, but imaginary, space coordinate.[7] Spatial coordinates and time were then replaced by *space-time*, a four-dimensional continuum with three dimensions for space and one for time, bound together by a space-time structure constant, which was none other than the speed of light, an invariant in all transformations.[8]

## General relativity

The general theory of relativity extended the scope of critical study of the concepts and formulation of physical theories related to the question of the relativity of motion by generally applying the invariance of the laws of physics to any (accelerated) motions. With this requirement, Einstein had the idea of expressing the basic fact of gravity (i.e. Galileo's law of falling bodies stating that all bodies falling from the same height have the same acceleration) as a 'principle of equivalence' (located at a given point in space-time) between a homogeneous gravitational field and a uniform acceleration force. A person inside a free-falling elevator is not conscious of falling, the fall being cancelled by the drift of the accelerated motion. This was consistent with the argument of there being a fundamental property in every gravitational field, related to accelerated motion. It was then possible to produce the (relativistic) theory of the gravitational field solely by considering *general covariance* (the same form of the law on transformations of coordinates for any movements). The mathematical representation of Minkowski's space-time diagram made it possible to formulate this statement, using non-Euclidean curvature of space (Riemann's geometry).[9] The form of space-time (given by the metric) is physically determined by the gravitational fields involved, according to the equations Einstein had formulated by late 1915.[10] The existence of the general theory of relativity demanded even more radical changes to thinking about the physics of space and time than did special relativity: space and time were not only interrelated, but were related to matter itself; space-time no longer stood as a framework outside the phenomena occurring within it, but was physically affected by them; relations of distance and time interval at any and every point were subject to the gravitational field at that point.

Three physical consequences arose directly from Einstein's theory: the perihelion shift of the planet Mercury, the fastest planet in the solar system, as observed in the mid-nineteenth century by Urbain Le Verrier but unexplained by Newton's theory of gravitation;[11] the bending of light rays in a gravitational field, which is equivalent to the curvature of space near large masses, as reported in 1919 when observing the solar eclipse mentioned above; and the red shift of the wavelength of light in a gravitational field, observed some time later. The extension of time, which is the parallel phenomenon, was later observed with accurate measurements on atomic clocks positioned near mountain ranges.

Other deductions arising from the general theory of relativity subsequently proved to be of great importance, for example, the existence (as posited by Einstein as early as 1916) of *gravitational waves* (variations in the gravitational field conveyed in space, such as space-time ripples); these ripples are to Einstein's relativistic theory of gravitation what electromagnetic waves are to Maxwell's theory. Indirect proof of the existence of these waves was found by R. A. Hulse and J. H. Taylor observing the oscillations of a binary pulsar (the '1916+17' system). It is extremely difficult to verify these findings because of the tiny level of the gravitational constant and the large masses of matter required. Projects like 'Virgo' in Europe and 'Ligo' in the United States are constructing giant antennae to detect gravitational waves coming from the cosmos (explosions of *supernovae*), and may provide the verification needed.

Other major consequences of the general theory of relativity concern very high-density celestial objects such as 'black holes' and even the emergence of cosmology as a science (see below). The general theory of relativity was remarkably fruitful for describing the physical universe, but this did not become apparent until the 1960s, with developments in astrophysics and observational cosmology. Prior to this, the theory had attracted the interest of a small number of researchers (mostly mathematicians), who worked on it for its formal beauty. It is now considered to be one of the principal theories of physics, along with quantum physics, and is seen as the theory of gravitation and cosmology.

## QUANTUM PHYSICS

Quantum physics is a subject of considerable scope, covering the deepest structure of matter in general, from cosmic objects to the bodies in our environment and the very atoms of which we are made. It provides an explanation for the unity of matter in the diversity of its organizational forms, from molecular combinations of atoms to the properties of the atomic nuclei and the elementary particles contained, actually or 'virtually', inside the nuclei. The tool for the theoretical understanding of this field is built around *quanta* applied to specific theoretical models (atomic or nuclear models) and extended, from a fundamental viewpoint, as the *quantum field theory*. As quantum electrodynamics, the theory can accurately describe the properties of atoms, determined by the electromagnetic interacting field. The most recent extensions of the quantum field theory, and covering other interactions operating at the level of the nucleus, include 'gauge fields'. They have been done in the conceptual framework of quantum mechanics, providing confirmation of its heuristic potential.

While the conceptual framework adopted in the late 1920s broke away from a number of features previously ascribed to the description of physical phenomena, it has given rise to problems of interpretation, for questions both physical and philosophical. Heated discussion among leading physicists of the age contributed to the founding of the theory.

### The quantization of radiation and atoms

The introduction of quanta to physics goes back to research on radiation conducted in 1900 by Max Planck. He developed a hypothesis on the discontinuity or 'quantization' of the energy exchange in the emission and absorption of a light ray at a given frequency.[12] Planck's ideas were taken further by Einstein's initial research in this field from 1905 to 1909 (on the quantization of light energy itself,[13] this being an extension of the quantum hypothesis on specific heats of atoms, the first form of the particle-wave duality of light) (Plate 68). This discontinuity, which became a fundamental feature of physical phenomena involved in atoms and radiation, meant the entire theory of physics had to be rethought, as it was based on the continuous approach of differential equations in mechanics as with electromagnetism.

In 1913, Niels Bohr presented a theoretical model of the atom, changing Rutherford's planetary model (with electrons moving in orbit around a core nucleus carrying almost all the atomic mass and having a positive charge), quantizing the electron orbits and thus accounting for the stability of the atom and for the energy exchanges in the emission and absorption of radiation[14] by the core nucleus. Soon after, in 1916, Einstein brought together data on quantum phenomena to form a synthetic theory, but which still featured classical concepts; this was the 'first theory of quanta', and the starting point for theoretical developments that led to quantum mechanics. Einstein calculated the transition amplitude between atomic levels and showed that radiation emitted or absorbed in these transitions had dual behaviour, as both waves and particles (a quantity of motion being the wavelength, and energy being the frequency).[15] These two features were retained in quantum mechanics and in fact provided the basis for its further development. In 1923, Louis de Broglie extended the wave-particle duality of radiation to cover all elements of matter[16] (the property being verified subsequently by the observation of the diffraction of electrons and then of other particles).

In 1924, Satyendra N. Bose and Einstein noticed that the quantum properties of physical systems for radiation and for certain single-atom gases[17] were intrinsically linked to the 'indiscernibility of identical particles'. This means that the physical state remains unchanged if two of the particles are interchanged (being symmetrical in mutual exchange), corresponding to a specific statistical behaviour pattern:[18] any number of particles in a system can be found in the same physical state and are therefore phase coherent. This produced a certain number of effects that did not exist in classical physics, and which will be discussed below: Bose-Einstein condensation (Einstein, 1925), the first example of a description of phase transition, superfluidity and superconductivity.

Parallel to these findings, Enrico Fermi and Paul A. M. Dirac discovered other non-classical statistics for another class of particles, which were indiscernible and anti-symmetric when mutually exchanged. When these statistics (Fermi-Dirac statistics) were applied to particles dubbed 'fermions',[19] they described a general property called the 'exclusion principle'. This principle had been formulated some time earlier by Wolfgang Pauli working on an empirical basis: he noted that, in a physical system, two identical electrons cannot be in the same quantum state (e.g. a given atomic level). This rule accounts for the way energy levels in atoms are composed and therefore explains the organization of the periodic table of elements.

Quantum mechanics integrated these basic properties into the formalism of the wave 'function' (or state vector) to describe a physical system, either symmetric or anti-symmetric, for the exchange of identical particles (respectively, bosons and fermions): these properties comprise one of the features of the 'principle of superposition'.

### Quantum mechanics

The foundations for what was to become quantum mechanics had thus been laid. Quantum mechanics was established in 1925–26, using two different approaches but producing equivalent results: *wave mechanics*, developed by Erwin Schrödinger working on the concept of matter waves (equations from mechanics are applied to a 'wave

function' in the system), and *quantum mechanics*, as developed by Werner Heisenberg, Max Born, Pascual Jordan and Paul Dirac, calculating transition amplitudes between atomic levels without the use of any classical image such as electron trajectories. This calculation of 'observable quantities' was equivalent to matrix calculations in linear equation systems. The formalism of quantum mechanics was developed on this basis, the physical quantities being depicted by *linear operators* (which, unlike numbers, do not commute when multiplied in pairs),[20] and the state of a system by a 'state vector' on which these quantities operate.

Schrödinger showed the equivalence between wave mechanics and quantum mechanics, and in the same year (1926), Max Born (Plate 69) presented his *probabilistic interpretation* of the wave function or state vector depicting the physical system: this function, $\psi$, produced by a causal equation (Schrödinger's equation), gives the probability so that the system it describes is in the state characterized by physical quantities at given values.[21] The function $\psi$ in physics therefore means a 'probability amplitude', and Schrödinger's wave is not a physical wave in the usual sense, but an abstract entity, a 'probability wave'. The quantity depicting a physical system, the state function $\psi$, has the 'superposition' property specific to such amplitudes: any linear superposition of functions, which are solutions to the equation of the physical system, is also a solution and can therefore describe the system.

This property proved to be one of the most fundamental in quantum mechanics, accounting for its most specific features such as wave-particle duality and the diffraction of quantum particles (e.g. electrons and neutrons), the indiscernibility of identical particles, as well as the local non-separability of systems of particles (see below), and the 'oscillations' of various electrically neutral systems of particles (e.g. of neutrinos).

In 1927, Heisenberg showed that 'conjugated quantities' operators that did not commute (e.g. position $x$ and momentum $p$) featured relations of inequality in their spectral width, such as: $\Delta x.\Delta p \geq \hbar$ (Heisenberg's inequalities). Such quantities, known as 'incompatible' or 'conjugated' quantities, therefore cannot be studied together to make a joint determination of absolute accuracy.

Quantum mechanics at the time was expressed with appropriate mathematical formalism; the state function of a physical system, with its (vectorial) property of linear superposition and physical value of probability amplitude, is defined in Hilbert's Space (the elements, or vectors, of this abstract space being the space of square integrable functions). The physical quantities were no longer expressed as numbers or numerical functions, but as mathematical, linear operators, acting on the state function of the system. The state of a physical system is determined by using a 'complete set of (observable) quantities which commute'.[22]

Quantum mechanics as developed this way (with the term generally including wave mechanics) was then able to account for the properties of matter and radiation, as well as their interaction. It constituted a body of doctrine, and from 1927, when presented at the Solvay Physics Conference in Brussels, it was recognized as a physical theory with mathematical formalism (more abstract than before), complete with interpretations capable of describing physical systems. In addition to physical interpretations, such as the probabilistic interpretation of the state function, when

quantum mechanics first emerged and for a long time after, it also included a 'philosophical interpretation'. In the minds of its proponents, this interpretation was designed for rational use, even though the principal statements were unusual, differing from concepts previously accepted in physics, e.g. the reality of described systems being independent of the action of the observer, and the determinism of the variables involved in the description.

## Quantum field theory

Quantum mechanics was then seen as a conceptual framework for describing physical systems, their development and interactions. But these same systems required that dynamics be developed to account for this behaviour, for example, to actually calculate the amplitude of atomic transitions instead of entering this factor on the basis of observational data. One direction that favoured development of the dynamics of quantum systems was the quantum field theory. During the late 1920s pioneering work was being done by eminent scientists such as Paul Dirac (Plate 70), Oskar Klein, Pascual Jordan and Eugene Wigner. In 1927, Dirac had devised a relativistic quantum equation of the electron, predicting the existence of antiparticles associated with known particles (identical except for opposite charges). This provided the foundation for developing the quantum field theory (at the time only in the electromagnetic field), based on a 'second quantization' approach whereby the state function was replaced by an operator that itself acted on the state. This meant that the creation or destruction of particles or antiparticles in a physical system could then be described, and it was therefore possible, in theory at least, to deal directly with interactions between atoms, nuclei, particles and fields.

This path and others were explored over the ensuing decades, with varying degrees of success. Efforts proved extremely fruitful in the field of electromagnetic interaction, with the development of quantum electrodynamics emerging around 1947; but it was not until the 1960s and 1970s that this perspective also became the path for other interacting fields discovered in the intervening period: the strong field of nuclear binding and the weak field of $\beta$ decay of nuclei and particles. Through these transformations, the conceptual framework of quantum mechanics remained intact, and physicists became accustomed to working with this intellectual tool, which is still essential for exploring quantum phenomena, from the atomic level to the level of elementary particles.

## UNCERTAINTIES ABOUT ACCURACY AND PROBLEMS OF INTERPRETATION

While quantum mechanics gave physical theory great potential for describing and forecasting phenomena in the atomic field, it also raised problems of interpretation quite unusual in the world of physics. First, the mathematical formalism of quantum physics, which had made it so fertile, seemed far removed from any 'intuitive physical meaning'; the mathematical properties of the quantities used (e.g. the state function as 'probability amplitude' and the principle of superposition) had only an apparently indirect link with the physical properties, despite being so accurately described

and forecast. Quantum theory seemed to mark the beginning of a new type of physical theory, comprised of abstract formalism extended by a physical interpretation of its elements, whereas in previous theories of physics, the mathematical form of the quantities was directly involved in the constitution of the theoretical relationships that provided the 'physical content'.

Most importantly, quantum mechanics seemed to cast doubt not only on determinism, through its solely probabilistic forecasts and Heisenberg's 'indeterminacy' relations, but also on causality with the 'postulate of reduction of the wave packet', supposed to account for the fact that one specific physical state was observed in superposition. Superposition was often seen as the result of random interaction between the measuring instrument and the quantum system studied. One unresolved question was of direct philosophical import: do material quantum systems exist as an independent reality?

### A philosophy of observation and complementarity

In a bid to justify the unusual procedures of quantum mechanics, Niels Bohr developed a philosophical interpretation known as the Copenhagen interpretation which was considered the 'orthodox line' for almost two generations of physicists. According to this observationalist philosophy, the properties of a physical system can only be contemplated independently of the conditions of observation. In the microphysical domain of quanta, this position required continued use of classical concepts, i.e. the concepts of the measuring instruments. The interaction of the measuring instrument with the quantum system perturbs the quantum system, and, because of the irreducibility of the quantum of action, the impact cannot be countered and corrected or overlooked, as would be the case in classical physics.[23] This perturbation in the observation process is apparently the underlying reason for Heisenberg's inequalities. These inequalities express the conditions of use (and limits of validity) of the conjugated quantities classically used in the field of quantum studies, and for that reason are often referred to as 'relations of uncertainty' or the 'principle of indeterminacy'. These relations are said to express a limit to the principle of omniscience, because even omniscience cannot avoid classical quantities and must at least use complementary viewpoints as an alternative so as to gain a complete view.

By placing the first reference of knowledge within the sphere of observation, thought concerning any physical reality is then subjected to the conditions of observation, and ultimately the concept of independent reality has to be abandoned. Heisenberg, for example, stated that physics did not concern 'real objects' but the 'inseparable object-subject partnership', that it did not concern nature but our way of finding out about nature. Under these conditions, the state function, $\psi$, would be understood not as depicting the physical system as such, but as collecting or cataloguing the knowledge acquired through observation and measurement.

### The reality of an individual physical system

While this notion prevailed for a long time with physicists, it was not accepted by all the 'founding fathers' of quantum physics, and notably Einstein, Schrödinger and Broglie. One of the important moments in the Einstein-Bohr 'debate of the century' – the now famous argument referred to as 'EPR'[24] – stands as the starting point in proof of a previously unnoticed quantum property: local non-separability. Quantum theory, through the principle of superposition, cannot provide separate descriptions of two physical systems (of particles) previously joined in a single system, regardless of the distance currently separating them and despite the lack of any physical interaction between them. For Einstein, this absence of local separability, which he showed to be inherent in quantum theory, indicated that the theory was unable to describe individual systems and was therefore 'incomplete'. He believed the apparent non-separability of quantum systems did not concern individual systems, and was simply the effect of the statistical description using the state function $\psi$.

It subsequently became apparent,[25] following theoretical research by John S. Bell and high-precision experiments on correlations at a distance conducted by, among others, Alain Aspect, that local non-separability was indeed an effective property of individual quantum systems. In general terms, quantum physics describes individual systems, albeit in a probabilistic way, as has been shown by experiments to isolate these particles in a beam without perturbing them.[26] A photon, or any other quantum particle (electron, neutron or even an atom), interferes with nothing but itself. Non-locality, which is the reason for this, seems to suggest that quantum systems cannot be depicted by proper spatial representation.

These conceptual and experimental advances cast light on the nature of the quantities specific to the quantum domain and helped make them directly intelligible despite their 'counter-intuitive' quality when compared to the more tangible quantities characteristic of classical physics. However, familiarization and adaptation to a world of quantum phenomena and objects still leaves open the philosophical question of the possible existence of an 'independent physical reality'.

### Measurement and reduction

One of the most puzzling of the different problems in interpreting quantum mechanics was still the problem of measurement or 'reduction'; this was also the problem of the relationship between quantum systems and the classical and macroscopic physical systems, and of the transfer of information from the former to the latter. The literature devoted to the subject is extensive and all sorts of solutions have been proposed, ranging from actual reduction caused by the interaction of the quantum system with a microsystemic part of the measurement device, to the absence of any reduction in physical terms, as with Hugh Everett's 'interpretation of the relative state'.

Recent experiments on the 'decoherence' of quantum states seem to have had a crucial effect, suddenly making it possible to 'visualize' an initial stage of quantum superposition in the measurement process, this being transferred to the measurement device, after which the state very quickly loses its phase coherence through the many interactions with objects in the environment in the macroscopic device. The measured quantum state ends up being randomly transferred to one of the basic states of the

preparation, according to the statistical distribution for the probability of that state. What remains important, ultimately, is the total state function of the system, in its superposition form; it is found by reconstituting the coefficients on the basis of statistical observations. Essentially then, as had already been suspected by a number of scholars, reduction might be simply a practical rule for expressing this set of operations.

If that is the case, a large part of the ad hoc philosophical arguments devised in order to rationalize our knowledge on quantum theory will have become redundant.

## THE ATOMIC STRUCTURE OF MATTER

Such was the influence of positivist ideas and doctrines of energy that physicists in the late nineteenth century were scarcely interested in the atomic structure of matter. Atomic physics came into its own in the early twentieth century when the physical reality of atoms was established by counting them and determining their dimensions. Theoretical predictions in the theory of molecular movements presented by Einstein in 1905, were tested in experiments conducted by Jean Perrin (between 1908 and 1913); this made it possible to determine Avogadro's constant (the number of molecules in a mole of substance) and also molecular dimensions, to $10^{-8}$ cm. These findings, together with others, clearly endorsed the physical nature of the molecular hypothesis and the reality of atoms.[27]

Atomic physics' first concern is the properties of atoms at the *microscopic level* of the individual atom or of aggregates of atoms as molecules, thus forming the first level of the physics of the 'infinitely small'. The discipline emerged early in the twentieth century from the study of molecular properties, the electronic constitution of matter and of radiation phenomena (X-rays, radioactivity, energy quanta and atomic spectra), first developing as the physics of the atom and its internal make-up. It also concerns the macroscopic properties of matter involved in this underlying quantum and atomic structure, and constitutes the focus of solid-state physics and the physics of condensed matter. The properties of atoms and the possibilities they have of forming molecular structures, or even as complex chains of molecules, are also relevant to chemistry.

### Radiation and atomic structure

A number of major discoveries in the late nineteenth and early twentieth century – the discovery of the electron, X-rays, the splitting of spectral lines in a magnetic field (the Zeeman effect) and radioactivity – corroborated the atomic theory of matter. The discoveries also provided indications of the composite nature of the atom, making it possible at the same time to gradually penetrate the atom's internal structure. From a theoretical point of view, an initial and decisive step was made with Einstein's work on the specific heat of bodies (1907), where he extended the hypothesis of the quantization of energy exchanges to cover atoms. Specific heats were cancelled out at absolute zero, as predicted by his calculations and confirmed in experiments conducted by Walter Nernst (c. 1914); this result stood as a crucial argument for accepting the quantum of action.

Ernest Rutherford's discovery of the atomic nucleus in 1911 led to a planetary model with a central, positively charged nucleus of tiny dimensions (a few $10^{-13}$ cm), in which nearly all the mass was concentrated. The nucleus was surrounded by a cloud of orbital electrons. But this mechanical model was not consistent with the atom's being stable (because of the classical law on electromagnetic radiation requiring electrons to lose energy continuously, radiating on their orbits). Niels Bohr modified this model in 1913, with his hypothesis of quantization of energies of electronic orbits; the only electron transitions allowed were discontinuous leaps from one orbit to another, with emission or absorption of radiation making the difference in orbital energies.

Bohr's theory of the atom, modified to take into account relativistic effects, explained the simplest atomic spectra. The characteristic quantities for the levels of the atom were subsequently specified by quantum mechanics in terms of four 'quantum numbers' describing energy, the kinetic moment, the magnetic moment and the 'spin' or intrinsic angular momentum.[28] According to Pauli's exclusion principle (1925), no two electrons can occupy the same state, and this determines the arrangement of the atomic electrons and explains the periodic classification of the elements (by successive levels of energy). It was later observed that the atom lines could be broken down into a 'hyperfine structure' ascribed to the spin effect of the nucleus; this discovery led to major applications in physics (nuclear magnetic resonance, first observed in 1937 by Isidor Rabi, and the MASER quantum oscillator, invented in 1954, measuring atomic frequencies with very high relative accuracy to the magnitude of $5.10^{-12}$), as well as applications in chemistry and medicine.

### Solid-state physics and condensed matter

Solid-state physics emerged in the early twentieth century with the quantization of the energy of atoms and the study of the crystal structure (in particular of metals), using $X$-ray crystallography discovered by Max von Laue and developed by William Henry Bragg and his son, William Lawrence Bragg.[29] Thanks to their efforts the configuration of atoms in all types of solids, both organic and inorganic could be determined.

The atomic theory of matter and later, quantum theory, could also be used to describe the magnetic properties of bodies in terms of directions of magnetic moments of elementary atoms, thus giving an explanation for paramagnetism (moments aligned in a magnetic field), diamagnetism (lack of direction, the alignment being countered by thermal agitation), and ferromagnetism (ordered magnetic states of paramagnetic bodies above what is referred to as Curie temperature). Paul Langevin, Pierre Weiss, Léon Brillouin and Louis Néel are the names of some of the pioneers in this field. Quantum statistics on electrons in solids, established by Dirac, Fermi and Pauli, made it possible to develop a quantum theory of free electrons in metals (Félix Bloch, 1928). In a crystalline solid, electronic states are divided into bands of energy in accordance with quantum rules, and the arrangement (in completely or partially occupied states, determining the mobility of the electrons) is what distinguishes insulators, conductors and semi-conductors (insulators at absolute

zero temperature, semi-conductors behaving as conductors at a non-zero temperature, and with conductivity increasing with the temperature).

The establishment in 1933 of a quantum theory of solids[30] boosted the development of solid-state physics and many new technical and industrial applications during the Second World War. The transistor, for example, was designed in the late 1940s in connection with advances in radar technology, and went on to produce the next generations of electronics and computer technology.[31]

The Mössbauer effect, a phenomenon of resonance produced by the absorption or emission of gamma radiation in a crystalline network at a very low temperature (Rudolf Mössbauer, 1958), proved to be of fundamental importance for studying the properties of solids, and also for applications in many other areas, ranging from atomic physics to astrophysics: it can be used to detect extremely small differences in frequency, such as the shifts produced by gravitational fields, accelerated movements and variations in a magnetic field.

The laser (acronym for light amplification by stimulated emission of radiation), developed in 1968, was behind many innovations in both *quantum optics* and solid-state physics. Many of its applications have changed our everyday life. The laser is based on the properties of semi-conductors and on 'stimulated emission' of light, a process predicted by the semi-classical quantum theory presented by Einstein in 1916, and which led to Alfred Kastler and Jean Brossel developing 'optical pumping' of atomic electrons by accumulating atoms in the excited state (1950). Lasers produce intense beams of coherent light of a specific wavelength from stimulated excitation of semi-conductors.

Beginning in the 1970s, major advances in low-temperature physics, and particularly the access to temperatures close to absolute zero,[32] opened the way for studying collective quantum phenomena that can be observed at a macroscopic level, such as superconductivity, superfluidity and Bose-Einstein condensation. Superconductivity, or the lack of any damping of electric currents through the Joule effect in a given solid that cancels out the electrical resistance, occurs in certain metals when their temperature is below what is referred to as 'critical' temperature).[33] Superfluidity is a 'phase change' from a gas or liquid state, e.g. helium, to a 'superfluid' state, with almost zero viscosity, perfectly homogeneous and without boiling; this occurs at a very low temperature (2K for *He*-4) by Bose condensation of part of the liquid, according to the model which Fritz London and Laszlo Tisza devised for *He*-4 in 1938. It was also observed (in 1972) for the isotope *He*-3.

Einstein had formulated a theory of *Bose-Einstein condensation* as early as 1925, seeing it as a consequence of the indiscernibility of quantum particles,[34] but for many years it had simply seemed to be an intellectual stance. It was not until the end of the twentieth century that the effect was observed under experimental conditions. This was because the temperatures needed had to be lower than one millionth of a kelvin, extremely close to absolute zero. The gas or liquid atoms, being physically identical and in phase, described by the same state function, can accumulate in an individual state of minimum energy, 'zero point energy', equivalent to a mean temperature of absolute zero, provided it is possible to stop the atoms from combining to form molecules and becoming solid. Once the atoms are shifted

and have no interaction, having lost their individuality within the collective physical system (and there may be a large number of them, from a few thousand to a significant fraction of Avogadro's constant), they form a condensate, a sort of super atom in the same state: this state of 'condensation' occurs at the macroscopic level and is observed as a perfectly homogeneous liquid with no viscosity, ready to fill immediately any space made available to it. A Bose-Einstein condensate was made for the first time under experimental conditions in 1995: a few thousand identical atoms of an alkaline metal were cooled to $0.4 \times 10^{-6}$ K, and accumulated in the same individual atomic state of 'zero point energy' for approximately ten seconds.[35] Other experiments have been successfully carried out since then.

Absolute zero temperature is a threshold value which, strictly speaking, can never be reached. The increasing difficulty of getting closer to it is expressed in the 'third principle of thermodynamics', as formulated by Nernst and Planck, which states that the entropy of any physical system goes to zero as the temperature tends towards absolute zero. This principle also defines an absolute scale for entropy (determined differently in a relative way, through differences in entropy).

These developments and others that cannot be included here concern macroscopic properties of atomic matter that are quantum in origin, and go beyond the bounds of solid-state physics and concern all 'collective phenomena'. This branch of physics is now more commonly referred to as the physics of condensed matter.

## Quantum chemistry

Over the past 50 years our understanding of the way atoms bind to form molecules, in particular on the tetrahedral structure of the valences of the carbon atom in three-dimensional space (providing the explanation of optical isomerism observed by Louis Pasteur), has been confirmed and expanded using X-ray crystallography. With this technology it is possible to determine the positions of the atoms in a large number of crystals, including complex molecules such as proteins (e.g. penicillin, discovered in 1944).

The first proteins were synthesized in 1907 and comprised chains of a large number of amino acids (polypeptides). This development opened a whole new field leading to the chemistry of macromolecules, whose existence was first proved in 1922 by Hermann Staudinger. It also revolutionized industrial chemistry (e.g. with fibre-form 'superpolymers' and plastics such as nylon, produced on an industrial scale from 1938 on) and *biochemistry*, and gave rise to the new discipline of *molecular biology*.

On the theoretical side, the electronic structure of matter meant that atoms bonding to form a molecule could also be represented as a particle comprising shared electrons. Quantum physics offered prospects for studying chemical bonding, understood in terms of *covalence* and *electrovalence*, the terms coined by Irving Langmuir in 1919. In 1927, Walter Heitler and Fritz London presented a theoretical description of the diatomic hydrogen molecule ($H_2$) as a resonance of the electronic waves for both atoms and applied this finding to the theory of chemical valence. Working along the same lines in the 1930s, Linus Pauling and John C. Slater found an explanation in quantum mechanics for the

chemical bonding of many molecules and, specifically, for the tetrahedral arrangement of the hydrogen bond of the carbon atom. Theoretical chemistry, considered equivalent to physical chemistry, then became quantum chemistry.

Experimental study of the structure of molecules benefited from all the resources of spectroscopy and, as of the 1920s, infrared and Raman spectroscopy. By the 1950s there were nuclear magnetic resonance and mass spectroscopy, which was important in determining molecular structures and looking inside them. Starting in 1937, work done by Pauling to determine the molecular structure of proteins using X-ray and electron diffraction techniques paved the way for molecular biology. There were also pioneering but more speculative contributions by physicists such as Schrödinger. Following in Pauling's footsteps came Francis Crick and James Watson who, in 1953, discovered the double helix structure of the DNA molecule.

## NUCLEAR PHYSICS AND ELEMENTARY PARTICLES

### Looking inside the nucleus of the atom

The second structural level of atomic matter is buried deep within its nucleus. The two levels, atomic and nuclear, are clearly separated by five orders of magnitude,[36] and research into the very tiny dimensions of matter opened up the new domain of nuclear physics. In the 1930s, nuclear physics truly emerged with the discovery of the neutron (the electrically neutral partner of the proton in the nucleus – James Chadwick, 1932),[37] artificial radioactivity (Irène and Frédéric Joliot-Curie, 1934), the production and systematic study of artificial transmutations and the new radioactive isotopes that could then be made[38] (e.g. Enrico Fermi who produced the first atomic pile in 1942), and exploration of the properties of nuclei.

Guided by theoretical models this investigation was done along two paths: one based on the classical thermodynamic 'water-drop' model proposed by Bohr, the other a quantum model 'in layers' that described the nucleus in terms of levels of energy, like the atom, with the different states being occupied by protons and neutrons. This path opened up the major chapter of nuclear spectroscopy, while the first path explained the behaviour of heavy nuclei with their large number of nucleons; when these heavy nuclei split they cause nuclear fission, an effect discovered in 1939 by Otto Hahn and Fritz Strassmann for uranium.

Once the heavy nucleus of uranium has absorbed a neutron, it splits into lighter nuclei, releasing energy: Lise Meitner and Otto Frisch explained this phenomenon using the water-drop model. The emission of neutrons during fission, observed by Frédéric Joliot-Curie, Hans Halban and Lev Kowarski, introduced the possibility of chain reactions, thus launching the idea of an atomic pile, for controlled reactions, but also that of a bomb, fulfilling the prediction of the special theory of relativity that 'matter is a reservoir of energy'.[39] Nuclear energy was released during the Second World War in the Los Alamos laboratory in the United States as part of the secret Manhattan Project to develop an atomic bomb before the Nazi regime developed one in Germany; it combined the skills of a large number of physicists, including many

European scientists who had emigrated for political reasons. This was the beginning of atomic energy's dual history – as a weapon in the Cold War arms race, and as a peacetime instrument for the development of nuclear reactors and power stations. A path for producing nuclear energy other than by fission was also opened with thermonuclear fusion; it became a reality with the making of the hydrogen bomb. The search continues for 'controlled fusion', i.e. exothermic synthesis of light nuclei such as deuterium, tritium or helium, from hydrogen. If achieved, this peaceful pursuit would offer the promise of an inexhaustible source of energy.[40]

For scientists to be able to explore the atomic nucleus, whether or not for these applications, they needed great penetration power: at least a few million electron-volts (MeV) of energy radiation,[41] i.e. the degree of magnitude of nuclear binding energies,[42] first supplied by radioactive bodies and by the acceleration of protons and light nuclei in electrostatic machines (accelerators: Cockroft-Walton, 1930, and Van de Graaff, 1931). Later, higher energy proton and electron accelerators made it possible to obtain elementary particles.

### Elementary particles

Nuclear physics and the study of cosmic radiation (discovered in 1912 by Victor Hess) gradually gave rise to the physics of elementary particles and discovery of a whole series of naturally accelerated particles, from 1930 on. After the electron, proton and photon came the *neutron* and the *positron*, the anti-particle of the electron as postulated by Dirac's theory;[43] then from 1936 to the late 1940s, the *muon* (a sort of heavy electron) and the *p meson* (predicted in 1935 by Hideki Yukawa in his theory of nuclear forces and finally observed in 1947). Next came 'strange particles' and the first 'resonances'. After this, accelerators reaching ever-higher energies (cyclotron, synchrotron and even supersynchrotrons and large electron and positron colliding rings) produced a large number of new particles by penetrating ever further into the fine structure of nuclear matter.

As a result, nuclear physics and elementary particle physics then became two quite distinct disciplines: the first focused on the structure of nuclei and their binding forces in a field where energy levels are relatively modest,[44] while the second targeted research into the elementary constituents of matter, to identify them and analyse the dynamics of their interaction. From an experimental viewpoint, particle physics featured a constant increase to ever-higher energies.[45] By the 1950s, the field was being referred to as high energy physics and ranked on the same level as subnuclear or elementary particle physics.

### The three interacting fields of subatomic particles

The study of nuclear reactions of nuclei and particles demonstrated a set of dynamic interactions different from those observed in an electromagnetic field:[46] the 'strong interaction' force, or more accurately nuclear force, is responsible, *inter alia*, for the cohesion of the nucleus, binding the protons and neutrons together, while the 'weak interaction' force is responsible for ß decay. These force

fields were the subject of major theoretical studies starting in the mid-1930s. Fermi took an hypothesis formulated by Pauli on the existence of a neutral particle with zero (or virtually zero) mass – the 'neutrino' – released in ß decay, and developed a theory of radioactivity. Subsequently a part of this theory was integrated into the theory of weak interactions, based on the quantum field theory developed for quantum electrodynamics.[47] However, in 1935, Hideki Yukawa submitted his theory of nuclear forces postulating that a particle of mass, intermediate between the electron and the proton, i.e. the meson, is exchanged between nucleons: the discovery of the $\pi$ meson in 1947 (a particle which exists in three states of charge) confirmed the validity of this approach.[48]

The properties of elementary particles concealed in nuclear matter were characterized by their behaviour in these three fundamental interactions. The quantum numbers that defined the states corresponding to these particles are in transitions between the different states, covered by conservation or selection rules depending on the type of interaction involved. In the degree of intensity (measuring force) and invariance (or conservation), being higher or lower, the interacting fields follow a hierarchy: strong, electromagnetic and weak, which means that a distinction can be made between stable (and relatively stable) particles and metastable particles or 'resonances'. Resonances decay very quickly through strong interaction:[49] these are the excited states of hadrons, the term used for any particle subjected to a strong interacting field.

The discovery in 1957 of the 'non-conservation of parity'[50] (left-right asymmetry) in ß decay, and also the decay of particles in a weak interaction, led to Fermi's theory being modified and generalized, while still retaining the validity of its structure: further work elucidated the concept of 'currents' (particles being transformed in interaction) and paved the way for later work done on symmetries.

Between the late 1940s and the late 1960s, hundreds of hadronic particles were discovered, both fermions (e.g. nucleons, known generically as baryons) and bosons (generically mesons).[51] The establishment of their spectroscopy as a function of characteristic quantum numbers (spin and parity, isospin, 'strangeness') uncovered regular features in their properties, making it possible to rank *them as state multiplets*, characteristic of a rule of symmetry for hadrons: *SU(3) symmetry*. The theory of groups of representations meant that by studying the mathematical properties of the phase changes they could be considered as combinations of other more elementary states, called 'quarks'.[52] Each of these quarks had its own characteristic quantity (high *isospin*, low *isospin*, *strangeness*), later generally referred to as *flavour*.[53] By 1962 three quark flavours were needed to cover all known hadronic particles; three decades later the discovery of families of particles of different flavours[54] meant the number had grown to six.[55]

These representations still only corresponded to the mathematical properties of the quantum states of the particles, which alone could not make them *physical* particles. However they did provide a simple theoretical understanding of the particles' properties of 'internal symmetry'.

After *hadrons* in the classification of elementary particles, came *leptons* and *photons*, both without strong interaction. Leptons (fermions with spin ½) included the electron ($e$) and the muon ($\mu$, a sort of heavy electron, first observed in 1937 in cosmic radiation), and their respective neutrinos, $v_e$

and $v_\pi$ (these being electrically neutral states). The neutrino-electron conjectured by Pauli in 1930 had been detected through its interactions by Frederick Reines and Clyde L. Cowan in 1953–56, working with a nuclear reactor. The independent existence of the neutrino-muon was confirmed in 1962 in a particle accelerator. A third pair of leptons appeared later, in 1977, with the identification of a charged 'heavy lepton' $\tau$ (together with its tau neutrino $v_\pi$). The photon ($\gamma$, zero-mass boson) was the quantum exchanged between charged particles interacting electromagnetically. Before long it was joined by other 'exchange bosons' from other interacting fields.

Experiments in scattering leptons (electrons, muons and neutrinos) and photons (all particles with no strong interaction, for which hadronic matter is relatively transparent) on protons and neutrons showed (between 1967 and 1973) that these *nucleons* had an internal structure shaped like hard seeds or *partons*, seen as the equivalent of the *quarks* in the symmetry groups. These quarks were therefore the *elementary physical constituents* of hadrons, which meant considerable simplification of hadronic physics, reduced to the properties of quarks, either bound or in interaction. But it was still impossible to extract and isolate them from the nuclear matter (to date no fractional charged particles have ever been observed): when excited, they recombine among themselves within the nuclear matter and produce ordinary hadronic particles.

The spatial dimensions of particles covered by particle physics range from the size of nucleons (a few $10^{-13}$ cm) to the upper limit of particles considered to be 'punctual', i.e. quarks and leptons ($10^{-18}$ cm), and the mass spectrum of elementary particles is spread quite evenly from zero (for the photon, and for a long time accepted as the threshold for the neutrino $v_e$) and 0.5 MeV (the electron), through a few GeV (for particles known in the 1960s), right up to hundreds of GeV since the 1980s.

### The structure of atomic nuclei

Throughout this whole period nuclear physics was continuing its investigations into the properties of atomic nuclei using two complementary approaches. The first analysed the overall behaviour of the set of nucleons, and the second focused on the properties of the nucleus seen as the sum total of the individual behaviour patterns of each of its component parts. The connection between collective motion and individual motion in the nucleus of the atom, which had been studied both experimentally and theoretically, had made it possible, *inter alia*, to describe the non-symmetrical configuration of the nucleus.[56]

The use of the first accelerated beams of heavy ions (starting in 1966) expanded the scope for studying nuclear reactions by providing access to levels of high angular momentum, and increasing possibilities for synthesising new and remarkable isotopes known as *exotic nuclei*, as well as *super-heavy elements* with atomic numbers higher than any previously known on the periodic table (extended to Z=112 in 1996). Heavy nuclei possess a large number of tightly packed energy levels with some even overlapping for high energies: the elimination of discontinuities meant (as with the water-drop model) that statistical mechanics and classical thermodynamics could be applied to them. This global analysis for collective phenomena, such as fission or

the formation of a compound nucleus, originally developed in nuclear chemistry. It was then generalized as nuclear macrophysics, with the study of collisions between two complex nuclei. Collisions of heavy ions also opened the way to another state of nuclear matter, where borders between individual nucleons were broken down, and where nuclear matter is seen as being comprised of free quarks and gluons, forming a *plasma* confined within the dimensions of the range of the strong interaction.

Certain aspects of recent developments on this and the concept of *nuclear matter* will be discussed below.

## Gauge symmetry fields and the 'Standard Model'

Another area of greatly expanded knowledge concerns the interactions of elementary particles. By the 1970s it was clear that the three force fields could be understood within the general framework of quantum field theory, previously thought to be restricted solely to the electromagnetic field. The theory of quantum electrodynamics, as proposed in 1947 by Richard Feynman, Julian Schwinger, Shin Itiro Tomonaga and Juan José Giambiagi, made it possible to determine the quantities involved in electromagnetic phenomena by a calculation of 'perturbations' reduced to convergent series, measured using the approximation required.[57] The greatest difficulty, which was the appearance of infinite quantities in the series development, had been resolved by a 'renormalization' procedure. This procedure was able to eliminate these quantities by an appropriate transformation related to the 'gauge symmetry' of the electromagnetic field, that symmetry itself being related to the zero mass of the photon, the quantum responsible for the electromagnetic coupling. The electrodynamic theory could then be used not only to calculate the value of the physical quantities, such as the mass and electric charge of the electron, and to do so with great accuracy, but also to explain new phenomena such as the Lamb effect.[58] The degree of theoretical and experimental accuracy also provided a limit to the spatial extension of the electron and of other 'punctual' charged particles such as leptons and quarks.

For a long time the properties of the other two types of interaction were an obstacle to any prospect for study by a similar theoretical approach. The punctual nature of the weak interaction required a quantum propagating the field to have mass too large for renormalization to be possible, and the high 'coupling constant' of strong interaction meant there was no hope of limited series developments. For a long time, both types of dynamic interactions between nuclear or elementary particles remained the subject of phenomenological studies, both theoretical and experimental. This debate thus paved the way for new syntheses developed since the 1970s, which would attempt to integrate and unify the fundamental forces within a single overarching theoretical framework.

This new approach was made possible first with the theoretical work being done on gauge symmetry fields, and secondly with the reduction of strong interacting particles into more elementary constituents – namely quarks, or punctual particles; this simplified the couplings of particles with the interacting fields. The role played by the electric charge in weak interaction appeared to be played by the quantities of weak charges characteristic of lepton and

hadron currents in interaction, and generically referred to as flavours. For strong interaction, the role seemed to be played by a quantity called colour,[59] which appeared as a constituent of quarks, and seemed able to bind them together.

The basic idea of gauge field theories is that the dynamics of particle interactions are determined by a property of invariance or symmetry of the quantities characterizing them: for weak interaction, the symmetry is related to weak charges or flavours. The electroweak gauge theory of Sheldon Glashow, Abdus Salam and Steven Weinberg (1967–68) sees electromagnetic and weak fields as simply components of a single field, described as 'electroweak'; it is symmetrical (or invariant) at very high energy with respect to 'local' gauge transformations viewed as an extension of the 'global' gauge of the electromagnetic field. Four field quanta (or bosons) are needed, two charged and two neutral, the neutral ones being mixed (as in quantum superposition); all of them in this state of exact symmetry, must have zero mass.

However, in weak interactions at the energies studied, this was impossible because the weak bosons, which had not yet been observed then, had to be of very high mass. Work then turned to a mechanism for breaking exact symmetry, known as the Higgs mechanism.[60] While separating weak and electromagnetic interactions, it assigned high mass to the three weak interaction bosons while retaining the zero mass of the photon. It was shown that renormalization of the component parts of the weak interacting field ultimately remained intact in this process, making it possible to make finite calculations of physical quantities.

The theory made a number of predictions, the two main ones being the existence of previously unobserved weak neutral currents (which are, as it were, the weak counterpart of the neutral, electromagnetic currents between the particles[61]), and the existence of three intermediate high mass bosons. The theory introduces a 'mixing' parameter between weak and electromagnetic fields, which is factored into theoretical predictions. Neutral currents were observed under experimental conditions in 1973, in the giant Gargamelle bubble chamber placed in a beam of neutrinos at CERN (Plate 71).[62] Their rate, linked to the electroweak parameter, suggested very high masses for the intermediate bosons, in the vicinity of 80 GeV (more than 80 times the mass of the proton). The three weak intermediate bosons, two charged ($W^{\pm}$) and one neutral ($z^0$), were produced and identified in 1982 with proton-antiproton colliding rings specially developed for this purpose at CERN.

After the success of the electroweak gauge theory, strong interaction was then studied in terms of gauge fields, which gave rise to the theory of quantum chromodynamics, developed from 1974 on. The punctual nature of quarks and their known properties shed new light on the structure of the strong interacting field: as the distances got tinier, their ability to interact faded to the point of disappearing. This asymptotic freedom provided the possibility for calculating series of perturbations. But their 'confinement', i.e. the impossibility of extracting them, was interpreted in quantum terms by a superposition of states which could not be dissociated or escaped from, and assigned to a quantum number, referred to as colour, which had to be introduced. Each ($q$) flavour quark[63] is itself a superposition of three different colour states, $q_1$, $q_2$ and $q_3$. Colour only plays a role in strong interaction, which is, however, invariant for

flavours. In fact, 'colour' can be understood as the 'strong charge' in the field carried by intermediate zero mass bosons, eight in number and electrically neutral, the *gluons*, colour field quanta exchanged between two quarks in their interaction.[64] Chromodynamics has proved very useful for conducting experiments in high-energy hadronic physics.[65]

## Prospects for further unification

The larger body formed by the electroweak theory and chromodynamics includes most of the theory of elementary particle physics and has been accepted as a standard model. Each of these theories has considerably simplified representations in its own domain, with one single explanation covering previously separate phenomena. But the theories do introduce 'free' parameters, i.e. produced solely through experimentation. What's more, while there is a relation between the two theories, they do remain fundamentally independent of one another. Ideas involving field symmetry have raised hopes of also being able to extend or unify ideas in greater symmetry, making it possible to go beyond these limits and reach a rational understanding of facts simply observed to date, such as the parallelism between the three families of quarks and leptons,[66] or the values of their masses.

In this way, work on unifying the three interactions has proceeded. The gauge symmetry that governs field equations is valid from a fundamental viewpoint, even though it remains hidden because it is not displayed directly in the phenomena observed (e.g. particles have masses which are all different, whereas the perfect symmetry joining them requires zero mass). Exact symmetries are only confirmed when masses (the result of symmetry breaking) can be overlooked: theoretical thought has therefore moved towards the domain of higher energies. The goal is a 'grand unification theory' where the three fields mentioned here converge, for example, merging quarks and leptons. This could mean coming back to the idea of a gravitational field, which has been sidelined, but will nonetheless have to be taken into account. The general theory of relativity would then give way to a quantized theory. An important first step in this direction has come from 'supersymmetry' theories. These mix fermions and bosons, or super strings with particles no longer seen as discrete points but as objects in space having more than four dimensions, and with the additional dimensions being folded in on one another.

## New trends in subatomic physics

By the 1980s, *nuclear physics* and *particle physics*, the two previously diverging branches that grew out of atomic physics, had begun to move back towards one another, not only in terms of their techniques and methods (producing differentiated beams at high energies, detecting complex interactions), but also through the nature of the subjects studied. If we think of the quark structure of matter, for example, the distinct borderline between the constituents of nuclei and particles has obviously become blurred. Nuclei and particles undergo the same fundamental interactions in systems, which are not always very different. Both fields include the study of neutrinos and are attempting to detect any 'oscillations' or spontaneous transformation from one

form into another; the findings have combined data from experiments conducted in both domains. The neutral currents of the weak interaction also exist in the nuclear domain and, indeed, also in atomic physics. The physics of hadrons is part of both nuclear physics and particle physics. These common concerns and the overlapping of subjects offer an incentive to see nuclear physics and particle physics as basically comprising the same discipline, i.e. subatomic physics. In their most differentiated parts, one focuses on research into the elementary and fundamental – as seen with the reduction of elementary particles and gauge fields – whereas the other focuses on nuclear matter in its complexity.

In nuclear physics, the concept of the nucleus (with its discrete levels of energy and the individual behaviour of the nucleons) has been replaced by the more general concept of nuclear matter with a diversity of structures, bound or unrelated, in ground state or excited, and covering not only nuclei and fragments of nuclei studied on Earth, but also compact celestial objects as big as neutron stars. The thermodynamics of ordinary matter (adapted to quantum conditions) has been applied to nuclear matter so as to account for properties at equilibrium or far from equilibrium. The theory shows two phase transitions: the first, similar to transformation from liquid to gas, has the atomic nucleus losing its identity by simultaneously emitting the nucleons comprising it; in the second, at very high energy, the nucleons themselves lose their identity in a plasma of quarks and gluons analogous to the ion and electron plasma of atom gases at high temperature.

Another highly significant convergence of disciplines to be discussed is that of nuclear and particle physics with astrophysics and cosmology.

## ASTROPHYSICS AND COSMOLOGY

Astrophysics first emerged in the nineteenth century when observation of the visible spectra of stars made it possible to identify their chemical elements. In the twentieth century the description was expanded, bringing new knowledge about the structure of matter. The equivalence of mass and energy quickly pointed to the idea that atoms might have arisen through a genesis process originating with the very simplest one – the hydrogen atom. Nuclear physics and knowledge of the properties of nuclei provided support for this idea, and the apparently inexhaustible source of energy in the Sun and stars was soon identified: it was, quite simply, nuclear reactions with light nuclei fusing into heavier nuclei. It could be said that the stars were ovens where the cosmos synthesized chemical elements that underwent changes in the course of time: the life and death of stars is directly attributable to competition between their tendency to collapse under gravitational force and the centrifugal pressure from the energy released in nucleosynthesis reactions. Advances in radioastronomy (radio, infrared, X-rays and gamma rays) have taught us still more about the properties of the stars and identified new celestial objects of various kinds, from radiogalaxies (discovered in 1953), to quasars, pulsars (in the 1960s) and intense sources of radiation.

In parallel, over the first decades of the twentieth century, astronomical observations provided more accurate knowledge of the galaxies, measured their luminosity, estimated distances and calculated the number of stars – an

average of 100 billion per galaxy. Cosmology, drawing on both the general theory of relativity and observation of distant regions of the Universe, had developed as a science in its own right; its main focus was the Universe, seen as a whole with its own structural make-up and evolution. While the vast structures of cosmology are concerned with the gravitational field, the elements and local sub-structures are the focus of astrophysics. The two have moved closer together over recent decades with the establishment of a standard model for matter and the Universe. It combines the model for the physics of fundamental interacting fields discussed above, and the model for evolutionary cosmology, known as the big bang.

## Astrophysics, stellar matter and new cosmic objects

As a consequence of their mutual gravitational fields, atoms in the same area of space gather together and 'fall' on top of one another: this is how stars and planets are formed. For a mass of matter in sufficient quantity (from slightly below one solar mass), the strong gravitational field compresses the atoms. They lose their electrons, forming a plasma where colliding nuclei (of hydrogen or helium for first generation stars) start a series of nuclear reactions forming heavier nuclei, which then, in turn, collide. In 1939, Hans Bethe submitted his theory of the fusion cycle; in it hydrogen is converted into helium, also producing neutrinos in the stars, and ultimately synthesizing carbon and then oxygen (Bethe-Salpeter cycles).

Stellar cycles include stable phases where combustion energy counters the gravitational force and gravitational compression phases when the stars cool down after they have exhausted their fuel: the density of the nuclei triggers new nuclear reactions producing heavier nuclei, and so it goes on until iron is synthesized. The lifetime of a star and its final state depends on its mass and density. Observation of new objects in cosmic space has provided a greater understanding of the different stages in the evolution of the stars: when compressed to extremely high densities, they are white dwarfs (gravity is balanced by the degeneracy pressure of the electrons, a directly quantum effect), brown dwarfs[67] (very dense but with mass too low to trigger combustion reactions), pulsars or neutron stars (observed for the first time in 1967, and with 400 now identified in our galaxy[68]), novae (a sharp, temporary increase in brightness), supernovae or extremely violent explosions with luminous flashes some ten billion times brighter than the Sun[69] (e.g. '1987A', which could be seen with the naked eye in 1987 in the Large Magellanic Cloud and emitted neutrinos detected on Earth), and black holes, so massive and dense that no light or radiation can escape from them.

Stars explode across space sowing nuclei of heavy and medium-weight elements. When they re-form, they, in turn, produce second-generation stars, and so it goes on and on. Space also contains cosmic rays (protons or nuclei) and gamma rays from sources that can be situated: these particles are usually the result of violent phenomena in the Universe, such as the activity of galactic centres or the explosion of supernovae.

Observational astronomy using optical and radio telescopes was recently strengthened by neutrino-astronomy, which uses neutrino detectors[70] to catch neutrinos produced in the stars (primarily in the Sun) and in the different cosmic phenomena. The ability of neutrinos to penetrate matter make them ideal for probing opaque objects in the Universe. Neutrinos emitted by the Sun are detected on Earth but found at a level that falls short of predictions. One explanation could be the spontaneous transformation of these neutrinos ($V_e$) on their path to Earth, forming a neutrino of a different family that may not be able to produce the corresponding lepton (which is heavier than the electron) and would remain 'sterile' instead of interacting in the detector.

Other outstanding celestial objects of a quite different nature are the extra-solar planets that are difficult to detect because of their distance, although towards the end of the twentieth century a number of these were finally detected both by direct means (visibility) and indirect means (effects of gravity on their star); and quasars, which are very intense, but very distant sources of light and more directly related to cosmology.

## The cosmology of an expanding universe

When developing his concept of general relativity, Einstein focused on the link between inertial mass and other masses in the Universe (Mach's principle); he then established the dependence of the metric structure of space as a function of the masses and energies it contained (sources of gravitational fields). In doing so, Einstein linked the idea of cosmology to the foundations of his physical theory. It was the general theory of relativity that determined the beginning of cosmology as a science: in 1917, Einstein raised the question of the conditions of the limits for relativistic space-time, i.e. the nature of space beyond the domain determined by gravitational fields. To avoid reintroducing absolute space in regions devoid of matter and extending infinitely, he had to accept – or so he thought – that the curved space of the Universe as a whole was closed. In geometry, Riemann had already dissociated the finiteness of space from its limits: finite spaces can be considered as having no limits, e.g. the two-dimensional space of the surface of a sphere.

Einstein then came up with the idea of applying his theory to the entire Universe, and of looking for solutions using simplifying hypotheses according to 'models' of the Universe. He devised the hypothesis of a 'cosmological principle', featuring homogeneity and isotropy in the distribution of the density of matter in the Universe; assuming that the radius of the Universe does not change with time, he introduced a 'cosmological term' that counterbalanced the impact of gravity. Alongside this cylindrical model of the Universe devised by Einstein, Willem de Sitter proposed a spherical model. Then in 1922 Alexander Friedman came up with the idea of a non-static universe, which was confirmed some time later with observations of the recession of the galaxies, and which Einstein eventually had to accept.

From an observational viewpoint, cosmology gradually established itself: by producing accurate calculations of astronomical distances, by realizing there were other galaxies well beyond the Milky Way, by observing the red shift of their spectral lines (Slipher, 1920), by calculating their distances (Edwin Hubble, 1920–30) and the proportional relationship between the spectral shift and distance, as formulated by Hubble in 1929 (Plate 72). Hubble's law (or the Slipher-Hubble relationship) indicated a mutual moving

away or recession of the galaxies.[71] Arthur Eddington interpreted it in the context of general relativity as observational proof of the Universe expanding, while Georges Lemaître, in 1930, presented his model of the primitive atom. In his view, the atom had exploded, giving birth to the Universe as we know it today and thus causing the galaxies to recede.

The theory of the expanding Universe was given spectacular confirmation in 1965 when Arno Penzias and Robert W. Wilson made the chance discovery of radiation at centimetre wavelengths in the cosmic background: isotropic radiation corresponding to the radiation of a black body at a temperature of 3 Kelvins. Such radiation had actually been predicted, in qualitative terms, by George Gamow in his hypothesis of a very hot Universe at the beginning of its expansion (the model now referred to as the big bang or 'primordial explosion').

In addition to these two major 'cosmological facts' – the recession of the galaxies and residual radiation – there was a third one concerning the *abundance of light elements* (De, He-3, He-4, Li) in the Universe that were stored in the stars. Their abundance was relative to the quantity of hydrogen.[72] Stellar nucleosynthesis alone could not explain the values observed, although they did tally with the predictions deduced from a state of great heat in the primordial Universe (primordial nucleosynthesis). The corresponding period had to have been very short because of the extremely fast cooling of matter as it scattered across the expanding Universe, for lower density meant that heavier elements could not be synthesized.

The general theory of relativity constitutes the framework needed to support cosmological theory; however, the exact form of the equations and the values of the solutions depend first on the simplifying but reasonable hypotheses used (e.g. the cosmological principle), and secondly on the parameters based solely on observation. Friedman's simplified cosmological equations, expressing the radius of global curvature of the Universe as a function of time, have three types of solution depending on the average value of the density ($\rho$) in relation to a 'critical density' ($\rho_c$).[73] The critical density is an exact compensation between the expansion and gravitational attraction of the constituent parts of the Universe. For any density less than critical density, the Universe is 'open' and expanding indefinitely; for any density greater than critical density, at a certain moment gravitational attraction will prevail over the expansion and the closed Universe will re-form, after reaching a maximum radius, moving towards a 'singularity'[74] symmetrical to the singularity of the primordial Universe.

Data from observational cosmology has provided us with information about the age of the Universe. This input can help make the theoretical model more accurate, with the prospect of forecasting the future evolution of the Universe. The value of Hubble's constant, depending on the value chosen,[75] sets the age of the Universe at between 10 and 17 billion years.[76] While the value of the average density estimated from the visible Universe is much less than the critical density (by a factor of approximately ten), it is also known that it is less than the real value that can be observed through the effects of gravitational force (the interaction of galaxies). In other words, the Universe contains 'dark matter' that is not visible, and the problem of determining this 'missing mass' is now one of the most important challenges for modern cosmology and astrophysics. This

missing matter may be quite diverse in nature: massive black holes of non-zero mass of 'fossil' neutrinos in the cosmic background, produced at virtually the same time and in the same quantities[77] as the isotropic electromagnetic radiation or 'exotic' particles[78] created at the very beginning of the cosmos' expansion and in sufficient numbers and with enough mass to constitute a predominant share of the energy and mass in the Universe.

This cosmology, backed by its fundamental theory (general relativity) and observational data which generally supports the hypotheses of expansion and the big bang, is today quite well established and has been endorsed and recognized as a standard cosmological model.

## The origin of the Universe

In its very early phases ('the first instants') evolutionary cosmology includes conditions that greatly restrict spatial dimensions and require extremely high energy density and temperature, equivalent to the conditions studied in research into subatomic physics (nuclear and particle physics). It pays special attention to that region where symmetries of interacting fields are increasingly close and where there is effective unification. Symmetries have been broken, fields differentiated and masses of particles have appeared as we move down the cosmogenesis timeline, with each period featuring a type of unification or differentiation of fields and of plasma of matter and radiation.[79] Next, continuing through time towards the present, we discover organizational forms emerging that are more familiar to us, forms such as galaxies (appearing around one billion years ago) of gas, dust, stars which form and fade, and other cosmic objects.

Cosmology thus offers an all-encompassing and coherent version of the genesis of the Universe and the objects it contains. It is reasonable to think that the Universe – in line with the implications of the general theory of relativity, of relativist and quantum cosmologies, as well as astronomical and astrophysical observations – has deployed its space and time in the movement of its own expansion, as space and time are not defined outside the matter comprising them. One of the most striking aspects of this theoretical representation is the intersection of the cosmology of the first instants and unified gauge field physics, and their convergence. This convergence began in the 1960s when it was realized that the two disciplines – one focusing on the distant cosmic background and the other on the innermost depths of the microcosm – were in fact one and the same. This convergence has continued to grow and the standard model discussed by cosmologists and physicists is now the juxtaposition of the model of unified gauge symmetry fields in particle physics and the big bang model in cosmology.

What then remains at the furthest point going back in time? It could be a mathematical singularity (a point with no dimensions, of infinite density), if arguing by extrapolation from the model developed from the general theory of relativity. But that theory is not the only one in these areas, where the other fields expressing the quantum structure of matter were actually dominant. Yet looking beyond the phase where the grand unification field dominates, i.e. times below a specific value known as 'Planck's time' ($t_P = 10^{-43}$ s), the gravitational field then recovers its value, playing a role as important as others, i.e. quantum matter fields, and it is thought that the gravitational field could be

unified with these. But the theory of the gravitational field under these conditions of space and energy needs to be transformed to comply with quantum conditions. Such a theory of quantum gravitation still defies efforts in theoretical research. This means we do not know the laws of physics for the period beyond Planck's time, and therefore that the concept of time has no physical meaning for us below that value. To persist in discussing time as if it were a continuous quantity, indefinitely divisible, is then nothing more than convention; and there is no proof that this same concept of time would be retained in a quantum theory of gravitation should it be achieved. In these circumstances, any reference to zero time is quite meaningless, for here we are grappling with the limits of our ability to even conceive of an origin of the Universe.

## MOLECULAR BIOLOGY

### Redefining the nature of living systems

The twentieth century witnessed three major scientific revolutions. In physics, the classical paradigm was questioned and two new schools of physics were established at opposite ends of the scale of magnitude: quantum physics and relativistic physics. The second revolution occurred in biology and led to the nature of living systems being redefined. The third revolution was the invention of the computer and the birth of information technology (Plate 73). The three revolutions were not independent: the revolution in physics provided inspiration for upheavals in biology; information technology (IT) and molecular biology emerged at the same time; and molecular biology adopted the metaphors of IT.

The development of life sciences in the twentieth century proceeded by stages: the early decades saw the development of two new disciplines, genetics and biochemistry, which laid the foundations for the new biology that first emerged in the 1940s. As was the case for physics, the revolution brought greater control over certain aspects of the world – especially towards the end of the century with its application to biotechnologies, molecular medicine and gene therapy. This new vision of the living world was named 'molecular biology'.

### The Birth of Molecular Biology

Many and varied are the arguments presented to explain the spectacular development of biology in the twentieth century, and many and varied are the models presented to account for the scientific 'phenomena'.

An inward-looking view of scientific development based on the interaction between models devised by scientists and observations obtained through advances in technology – constantly shifting and going deeper (or more accurately to ever more elementary levels of organization) – sees the boom of molecular biology as simply the completion of a movement first begun in the Renaissance, at the dawn of the scientific revolution. In this worldview, life sciences were established in the seventeenth and eighteenth centuries (although the term 'biology' was not coined until the nineteenth century); their goal at the time was to explain the properties of living beings. This meant analysing the complexity of biological phenomena, breaking them down to their simplest elements. In parallel, the movement contributed to the discovery of the hierarchical organization of the structures that comprise living beings. In the seventeenth and eighteenth centuries physics had set the example. By the middle of the nineteenth century, encountering difficulties associated with an excessively mechanistic description of living organisms, biologists had chosen chemistry as the indispensable partner in their work. At the same time, the invention of more powerful microscopes in the nineteenth century led to the development of cell theory. But biologists did not stop at that level of complexity: they went beyond the cell to discover the remarkable properties of the cell nucleus and then of the chromosomes inside. And in the meantime, the catalytic properties of enzymes had been slowly uncovered, explaining the amazing chemical properties of the cytoplasm.

The twentieth century simply took this characterization of the fundamental components of living organisms a step further. Chromosomes proved to be gene containers, and the young science of genetics showed the fundamental role they played in determining heredity. This branch of science, which should be credited to Gregor Mendel, the nineteenth-century Russian monk, was not understood and used until it was 'rediscovered' in the early twentieth century. Genetics benefited from the dynamic impetus of Thomas Hunt Morgan's research team at Columbia University in New York City. Using just one organism as a model, the fruitfly (*Drosophila*), Morgan and his team showed that genes were located on chromosomes (Plate 74). This observation allowed them to create the first genetic maps. Other groups extended these findings to different organisms, both animal and vegetable. Genetic analysis was becoming increasingly accurate, and the localization of genes on chromosomes was becoming ever more reliable; however there remained much to learn about the nature and functioning of genes. At the same time, the characteristics of enzymes were being documented; they were identified as proteins, and painstaking work to determine their structure began. Molecular biology emerged in the 1940s when these two experimental approaches combined both their techniques and questions, and when the chemical nature of genes and their role in protein synthesis were determined.

For anyone who believes that the development of science is mostly a response to external forces, the boom in molecular biology would appear as a response to problems affecting industrial society in the early twentieth century. On the one hand, advancement of science, particularly physics, gave us technology and its control of the inanimate world; and with it there is continuing economic growth (at least in industrialized countries). Yet on the other hand there are social and health problems associated with mental illness, crime, tuberculosis and sexually transmitted diseases – afflictions often passed on from one generation to the next. Faced with these challenges, it was tempting for some (the eugenicists) to take the findings of studies into hereditary conditions and apply them in full to reverse the supposed deterioration of human germ plasma. Another response was advocated by members of the Rockefeller Foundation, liberals determined to combine industrial progress and social progress. These enlightened minds believed biological sciences should catch up with the physical sciences. Deeper knowledge of living organisms, they claimed, would

inevitably enable us to more successfully control problems affecting the biological foundations of human society.

The role of the Rockefeller Foundation in the rise of the new biology has been the subject of lengthy debate. Some believe it was fundamental, combining pro-active work with financial incentives that attracted physicists to molecular biology – encouraging them to devise new techniques and technologies to study living organisms, and helping them equip their laboratories accordingly.

This view is no doubt far too geographically limited, for the same trend is found in all countries where biological research had reached a similar level of development (e.g. the USA, France and the UK). Surely the Rockefeller Foundation was not so much the driving force as simply supportive and attentive to those who saw the future development of biology in using both the concepts and tools of physics.

Whether through its own development or through a deliberate choice made by political and economic decision-makers, it is clear that everyone saw how future advances in biological knowledge could be achieved through the application of physical theories and techniques, by focusing on the elementary constituents of living organisms and their complex macromolecules.

Molecular biology emerged triumphant from the meeting of such diverse disciplines as biochemistry and Morgan's genetics. No one today would challenge the molecular view, but that was certainly not always the case. In neither the Soviet Union nor Eastern Europe was genetics accepted until after the Stalin era. Lyssenko (1898–1976), a fanatic anti-geneticist, even succeeded in having genetics dismissed as a 'bourgeois science', promoting instead a vague pseudo-scientific theory influenced by Lamarckian ideas.

Domestic and foreign political considerations in the Soviet Union explain much of Lyssenko's success. Morgan's genetics also faced opposition in many countries, including the United States, France and Germany. Genetics stood in opposition to other biological disciplines such as embryology, yet gave no explanation of the role of the genes in the development of the embryo. It was not until the 1960s that molecular biology began to produce models able to meet the demands of developmental biologists.

### Stages in the molecular revolution

The main discoveries that helped establish the new view of living organisms occurred in the period between 1940 and 1965. They arose from the choice and construction of model systems for studying the fundamental relationships among the constituents of living organisms. In the first half of the twentieth century, the fruitfly had contributed to the growth of genetics, but micro-organisms, and in particular the common intestinal bacteria named *Escherichia coli*, provided the optimal test organism for molecular biologists. For a long time doubt had persisted as to whether these elementary organisms possessed genes, but this was dispelled when the mechanisms of genetic action and their role in coding proteins were uncovered thanks to these micro-organisms. The molecular revolution was also built on the use of new tools: while there were electronic microscopes, the images they captured were often difficult to interpret; the techniques of physical and organic chemistry could be used to isolate the macromolecules in living organisms, and specifically in

proteins, highlighting how the composition and structure play an essential role. Nuclear physics contributed by providing the isotopes of the main atoms that make up the macromolecules in living organisms and offering options for tracking transformations of these molecules, either in samples or inside the cells and living organisms.

The combined use of models and techniques between 1940 and 1965 helped illuminate the basic molecular mechanisms that control the functioning and reproduction of living organisms. In 1940, unequivocal proof was given of the clear relationship between a gene and a corresponding enzyme (a protein): the relationship had been inferred since the early twentieth century, but by using one micro-organism (a fungus, *Neurospora crassa*) it could be generalized. In 1944, O. T. Avery et al. showed that genes were made of deoxyribonucleic acid (DNA). This finding was in direct opposition to previously accepted ideas. The structural and functional diversity of proteins were already well known, so proteins were chosen for investigating the chemical nature of genes. Eight years after Avery's experiment, a second experiment was conducted on the bacteriophage to show that the genetic material did indeed contain DNA; then in 1953, J. D. Watson and F. Crick discovered the double helix structure of DNA. This was immediately acclaimed for the 'beauty' of the structure and because it provided a simple explanation for the self-replicating properties of genes. The code was deciphered between 1960 and 1965, when scientists finally understood that a protein corresponds to one specific fragment of the DNA molecule, called the gene. Over the same period, regulatory mechanisms controlling enzymes, proteins and genes were identified. Once these regulatory models had been constructed, molecular biologists could, with complete faith in their explanatory diagrams, move away from the study of micro-organisms and embark on the study of complex multicellular organisms and their development, i.e. their gradual formation from a single cell.

### Moving towards the study of complex organisms

Over the next ten years, molecular biologists studied the complexity of these multicellular organisms, but with little success. The period between 1940 and 1965 had provided biologists with a fine framework for interpreting basic phenomena in the living world. However the tools developed to study micro-organisms proved unsuitable for complex organisms. With research at a standstill, existing models were discarded and other, more complex models were devised, but again without success. This period of doubt and questioning must have been necessary for molecular biologists to realize just how complex the levels of organization were inside living organisms – molecules, organelles, cells, tissues, organs and organisms.

Doubts and questioning of models continued until the tools of genetic engineering eventually provided the long-awaited resources. The discovery of restriction enzymes that can cut the DNA (genes) at specific points has often been cited as marking the birth of genetic engineering. Genetic engineering is, in fact, a complex range of techniques used to: (a) isolate genes; (b) make fine characterization (determining the sequence of proteins they code for); (c) make transfers from one organism to another (with the possibility of producing transgenic animals and plants, i.e.

with new genes integrated); and (d) modify or mutate them to change their function or regulation.

The advent of these new tools was greeted with apprehension, first by biologists and then by the general public. There were questions concerning the risk of spreading pathogenic genes in the wild and to the human species, and whether a natural barrier, which had previously separated the species, might be broken down. The decision was for a moratorium on research that was only lifted once very strict measures had been adopted to restrict any danger arising from genetic manipulation. The measures did not put an end to the controversy, however, although favourable reports came in and no accidents occurred. Gradually, the storm settled down and precautions adopted were eased.

With these new tools, information could be collected at great speed which, when presented as findings, would sometimes cast doubt on dogmas in the new discipline. There was the discovery that genes of higher organisms were split into many different pieces; this explained the substantial increase in size of genomes in the course of evolution, although it was difficult to see what advantage had been gained from such genetic complexity. This period of questioning was short-lived, for the mass of data and findings that accumulated using the tools of genetic engineering produced strong backing for the molecular view of living organisms developed between 1940 and 1965.

By 1986, with the volume of findings and the speed at which they were obtained, biologists were contemplating the possibility of determining the complete structure of the human genome. This mammoth task, which could be compared to the Apollo programme to conquer space and put a man on the Moon, raised fears (or hopes) that biology was moving into the 'Big Science' arena. Since the time when the basic concepts were first formed, the programme had changed substantially, not in terms of the ultimate objective, but in terms of organization. Sequencing of the genome had become a final stage, following the mapping of the human genome, offering the possibility of quickly localizing and identifying the genes involved in diseases. More important was the extension, after sequencing the human genome, to sequencing simpler genomes, such as bacteria and single-celled nucleate organisms like yeasts. The first complete genome sequences were determined in 1995 and 1996, no doubt heralding a new stage for biology (Plate 75).

## Biology today

While molecular biology was developing, it was also 'redefining' life. Definitions of living organisms that had been accepted since ancient times gradually receded. The borderline between things living and non-living faded. The distinguishing feature of a living organism was no longer the nature of its constituents or properties, but simply the complexity of its macromolecules comprising it. Aside from the redefinition of life itself, the most characteristic feature of the molecular revolution is the profound unification achieved in the biological sciences. While biochemistry, genetics, development biology and cell biology have retained their own specific features, they all have the same molecular interpretation of the phenomena observed and also share a large number of technologies. The techniques of molecular biology have become indispensable tools for the many other biological disciplines, including population genetics, taxonomy and even palaeontology and ecology.

The new molecular view exposed the deep-seated unity of the living world: unity in the nature of the constituents and also in the rules of the correspondence between the structure of genes and the structure of proteins, rules respected by all living forms known today. This fundamental unity highlights the single origin of all living beings, yet goes beyond the basic constituents behind all primary living forms. What do the structure of a fly and the structure of a human body have in common? Or the compound eye of the fly and the human eye? Yet the same genes are used for both. To explain this strange phenomenon, the French biologist François Jacob chose the metaphor of DIY – do-it-yourself – work. With the passage of time, evolution has worked using the tools available, i.e. the genes ready at hand, using them again and again to build either analogous structures or, the opposite, to build structures that are different but perform new functions. These findings show that to understand the workings of living beings, biologists should not just focus on the structures they discover, but should look to their evolutionary origin. The intention is not to discredit Darwin's model of the evolution of living beings, but the DIY view does provide a counterweight to an excessively 'Pangloss-like' view of evolution, whereby the presence of any structure might be explained in terms of its having some selective advantage. Through its corrective lens, the DIY interpretation shows just how many constraints were involved in the creation of living forms.

The unification that came about with molecular biology has sometimes been held against it, with allegations that it was achieved by downgrading – or reducing – the description of the functioning of living beings to its most elementary level. It is true that in the 1970s certain molecular biologists might have overlooked the organizational complexity of living beings, seeing nothing more than molecular exchanges and interactions. It was thought that individual facts could be memorized and stored in the brain as molecules, just as the genetic memory is stored as DNA. This is no longer the case today, and contemporary biologists have explained living phenomena at the molecular level, after first describing them at a supra-molecular level, as a cell or organism. The 'reductionism' of molecular biology is in fact only partial. Molecular biologists do not set out to produce descriptions at the atomic or electronic level when reporting on interactions between macromolecules, or between proteins and DNA. In most cases, a rough description in terms of mechanisms is sufficient and can even be more relevant.

Physics provides another counterpart to the reductionism of molecular biology. This is particularly surprising for, as we have seen, physics played a major role in the emergence of molecular biology: it provided a model, it contributed both techniques and the scientists who were instrumental in its growth and who, in many cases, had been trained in physics. In the 1940s and 1950s, these scientists dreamed of electronic biochemistry, a biological science as fundamental as its senior discipline. It was thought that cybernetics, the science of controlled systems, based on simultaneous observation of living beings and machines, would inevitably forge the way to designing theoretical models able to account for the physiological properties of cells or organisms. While molecular biologists today still use the concepts of information theory and cybernetics to account for relationships between genes and proteins, it is merely a

metaphor; the complex concepts drawn from information theory (IT) have never found a place in molecular biology.

Why, to this day, do biologists still attempt to describe the most complex regulatory mechanisms using approximate mechanical models without any formalism or equations? Surely there is a weakness in this new biology, which must be corrected if the doors of complexity are to be opened for researchers. In addition to this enduring absence of theoretical biology, there is the disconcerting development of techniques that biologists had temporarily borrowed from physicists. The techniques have now been simplified and made 'democratic'; they can be used without any theoretical or practical expertise in physics. This trend in modern biology stands as a formidable enigma challenging philosophers of science and epistemologists who had built their model by studying physics and had used the historic developments of physics to adopt its evolution as a paradigm for the evolution of all the sciences. Perhaps new biology has simply lagged behind in this evolution, in which case it is high time for it to catch up. Modelling will probably arise 'naturally' with the very rapid acquisition of knowledge achieved through genome sequencing programmes and the ever-increasing use of the IT tools required for this. But it may also be that in a few years' time, developments in physics will appear as applying to that field only (or to a few other disciplines), and that the history of biology may present a different kind of scientific evolution.

While modern biology has not followed the path of physics, it has adopted one of its specific qualities – efficiency. In the past, biologists could only observe living organisms, but today's biologists can act on the organism, and change it. At present the applications may seem trivial: enabling bacteria to produce human hormones, producing a parasite-resistant plant, or mice as big as rats; these are mere curiosities. Quite obviously biologists have not yet mastered all the complexity of living organisms, but their knowledge has already been put to use and small advances may lead to a substantial expansion of the means of action available.

## Molecular biology and beyond

The development of any science is always dependent on other factors. In rational terms, two paths seem to be opening up for molecular biology: one is heading towards an increasingly elementary level of living matter, while the other is returning to complexity by integrating molecular observations. Both developments have been expected for a number of years, and some researchers are waiting eagerly. However, the recent development of molecular biology (which could also be seen as its non-development) demonstrates that caution is required.

Molecular biology has not abandoned its current paradigm, but is still undergoing change. Two related fields of research are expanding rapidly: development biology and evolutionary biology. Development biology has characterized essential genes involved in constructing multicellular organisms and has shown how these genes have been conserved over the course of evolution. The question now raised is whether analysis of these genes will uncover a logic behind the make-up of complex living organisms, or whether these genes are only 'tools' that higher organisms have used to construct themselves, according to rules and logic yet to

be understood and which may only be uncovered at a different level of complexity.

The discovery of 'development genes' will no doubt lead to radical change in prevailing theories of evolution. Darwin's theory must no longer stop with natural selection and the complex interplay of the variation of multiple and non-identified genes. Surely the only genes with variations that are relevant to evolution are precisely these development genes. Surely these are the genes which, when they appeared or were modified, were part of or even *the* reason for the main branches growing out from the evolutionary tree, as for example, with the explosion of living forms observed in the Cambrian period. When defining an animal, instead of attempting to describe properties (e.g. motor skills) as points of reference in relation to organisms that do not have the properties in question, surely it would be more accurate to characterize all the development genes the animal possesses; given their role in the structure of the organism, they are what defines the 'zootype'.

There is, however, one last area of research, which has so far stood up to the attacks of biologists and also artificial intelligence experts, and that is the workings of our brain and cognitive faculties. In the 1960s, after the basic mechanisms involved in the function and operation of living organisms had been established, many molecular biologists saw a new frontier in brain research where they might use some of this recently acquired knowledge. Indeed, Max Delbrück, a founding figure in molecular biology, had set the example when he abandoned his study of bacteriophages to work on a phototrophic fungus, in the hope that he would uncover the elementary principles of sensitivity and nerve function.

Years have gone by. Molecular biologists have been instrumental in laying bare the extraordinary complexity of nerve cells and the brain. It is believed that a large part of the human genome (70–80 per cent) is made up of genes specifically expressed in the nervous system. The small molecules, which transmit signals between cells and the membrane receptors they bind to, have been characterized. Some of the enzymes involved in stabilizing these signal transduction paths, and therefore in memory, have also been characterized. Using the technique of homologous recombination (once a gene has been identified and characterized, it is replaced by a non-functional copy), neurobiologists have been able to show that the genetic coding for these receptors or enzymes is clearly also involved in the workings of the brain and memory. However, there is no guarantee that the greatest advances in neurobiology will come from these molecular studies, for they uncover the nature of the materials used to build the central nervous system, but do not explain the functional organization. Nor is research into artificial intelligence or the work (of variable quality) covered by the term 'cognitive sciences' likely to advance studies on the brain; while they are important for progress in information technology and systems, only rarely do they give consideration to existing knowledge about the structure of the central nervous system. In most cases, the key objective is not to describe what happens in the brain, but to provide new tools for developing 'smart' machines achieving ever-greater performance levels. New technologies, however (magnetic resonance imaging, MRI, and positron emission tomography, PET) have made it possible to 'see' the brain at work and thus describe the structures involved in each type of behaviour. For a number of years now, these

have been revolutionizing our knowledge of the central nervous system. They have provided convincing arguments that support the existence of mental images as postulated by psychologists for so many years. Progress over years to come in our knowledge of the human brain may not be, therefore, at the most fundamental level. It could be that the development and expansion of these studies may well signal the end of the golden age of molecular biology.

## FUNDAMENTAL CHANGES IN THE NATURAL SCIENCES AND MATHEMATICS

At the second International Congress of Mathematicians held in Paris in 1900, the German mathematician David Hilbert gave a remarkable lecture presenting twenty-three problems, which he believed could keep research occupied for years to come. His goal was to show just how vital the mathematics of his time was and to note that advances in mathematics result from research into problems.

Hilbert's first six problems concerned fundamental questions on set theory, arithmetic, geometry and probability: (1) the continuum problem, posed by Georg Cantor, on possible cardinal numbers for the infinite subsets of the straight line, (2) the consistency of arithmetic axiomatized by Giuseppe Peano, (3) the need for infinitesimal methods to calculate the volume of a pyramid, (4) the classification of geometries where a straight line is defined as the shortest path between two points, (5) analysis of transformation groups with continuity being the only assumption, and (6) the axiomatization of calculations of probability and mechanics.

The next six problems concerned the theory of numbers: (7) transcendence of numbers in the form $\alpha\beta$ where $\alpha$ and $\beta$ are algebraic, $\alpha \neq 0, 1$ and $\beta$ is irrational, (8) Riemann's hypothesis on zeros in the function $\zeta(s)$ and the distribution of prime numbers, (9) general reciprocity laws for $\ell$-th power *modulo* residues an ideal prime of a number field, (10) a decision algorithm for the existence of integral solutions to Diophantine equations, (11) the theory of quadratic forms with any number of variables and with coefficients in a number field, and (12) construction of Abelian extensions of a number field using special function values.

The next two problems were algebraic: (13) is it possible to solve the general equation of the 7th degree by formulae using functions of only two variables? (14) the existence of a finite number of generators for certain sub-rings of a field of rational functions. Then problems number 15 (a rigorous foundation for Schubert's enumerative geometry) and number 16 (the number and arrangement of the connected components of a real plane algebraic curve, the number of limit cycles for a differential equation) concern algebraic geometry, while problem 17 (can any positive definite form be expressed as the sum of squares?) is another algebra problem. Problem 18 concerns Euclidean geometry of a higher dimension; basically it involves classification of crystallographic groups.

The last five problems deal with the theory of functions and differential equations: (19) the analysability of solutions to regular variational problems, (20) the existence of a solution for boundary value problems arising from regular variational problems, (21) the existence of a Fuchs type linear differential equation with given singularities and a given monodromic group, (22) the uniformization of analytical relations by means of automorphic functions, and (23) the development of methods in the calculus of variations.

While some of these problems, for example the third and fourth, were solved quite quickly, others have kept research going for many years and have led to new theories which, in turn, have left their mark on twentieth-century mathematics. Hilbert's problems 8 and 12 remain beyond our reach.

Problems 1, 2 and 10 have been the subject of research in *mathematical logic*. The discipline emerged from a programme on proof theory formulated by Hilbert in the 1920s in an attempt to solve problem 2. The programme institutes a formal method where the mathematical theories studied are codified using a set of symbols assembled according to explicit rules of syntax to write up the propositions and proof of the theory; the meaning of the statements is set aside to focus study solely on the groups of signs, using rigorously finite reasoning. In 1931, the Austrian logician Kurt Gödel succeeded in demonstrating the impossibility of proving the consistency of a formalized theory containing Peano arithmetic without using more powerful resources than those found in the theory being considered; such a theory by definition contains undecidable statements, i.e. while they cannot be proved, they cannot be disproved either. In 1938 Gödel proved that while the axiomatized set theory is consistent, it can be associated with the continuum hypothesis (whereby one infinite part non-countable on the right has the power of the continuum) without introducing inconsistency. It was not until 1963 that the American mathematician Paul Cohen showed it is possible to associate the negation of the continuum hypothesis without introducing inconsistency; and therefore the continuum hypothesis is undecidable in set theory. These proofs of *relative* consistency are based on the concept of a *model* for formal theory, and theoretical work on this had started in the 1930s with research by the Polish logician, Alfred Tarski. The symbols and propositions in a formal theory were assigned to subjects and statements of a theory believed to be known (e.g. set theory), in such a way that the axioms of the formal theory correspond to the true statements in the model; a formal theory that accepts a model will not be inconsistent if the theory used to provide the model is not inconsistent.

In 1970, the tenth problem was solved by Yuri Matiyasevich; the solution is negative, i.e. the algorithm in Hilbert's question does not exist. Work by logicians in the 1930s had helped specify what had to be understood by algorithm and computable function; reference can be made to the notion of recursive function devised by Gödel and the Turing machine concept of the English logician Alan Turing. According to Gödel, there are sets of natural numbers that are recursively enumerable (sets of recursive function values) but not decidable, i.e. there is no algorithm for deciding whether a number belongs to it or not. It is also noted that a set of natural numbers is Diophantine when it is the projection of the set of the solutions to a Diophantine equation, i.e. a polynomial equation with integral numerical coefficients where the unknown quantities must be whole numbers. In 1952, the American logician Julia Robinson established that, to prove that any recursively enumerable

set is Diophantine, a Diophantine predicate of 'exponential growth' was all that had to be constructed; a Diophantine predicate expresses belonging to a Diophantine set. This is exactly the construction devised by Matiyasevich: he proved that the property '$n$ is the $2m$-th Fibonacci number' is an exponential Diophantine predicate.

The axiomatization of probability calculus was the subject of a great deal of research in the first thirty years of the twentieth century. In 1933, the Russian mathematician Andrei Kolmogorov published a monograph detailing the fundamental axioms for calculating probability; it links up with the theory of measurement and integration developed earlier in the century by Émile Borel and Henri Lebesgue. The basic concepts are *event*, *probability* and *random variable*. The events are certain parts of a set $\Omega$; these parts form a *sigma-field*, i.e. that the complement of an event is an event and that the union of a series of events is an event. The probability of each event $A$ is assigned a number $p(A)$ between 0 and 1; the probability $p(\Omega)$ of the *certain* event $\Omega$ is equal to 1 and, where $(A_n)$ is a series of two-by-two disjointed events, the probability of them being reunited is equal to the sum of the $p(A_n)$. This definition needs to be completed by including the definition of conditional probability: let $B$ be an event with non-zero probability, then the probability $p(A|B)$ of $A$, given that $B$ is occurring, is defined as the quotient

$$\frac{p(A \cap B)}{p(B)};$$

where it is equal to $p(A)$, i.e. where $p(A \cap B) = p(A).p(B)$, events $A$ and $B$ are said to be independent. A random numerical variable is a function $X$ over $\Omega$ with real values and so that, for any interval $I$ in real numbers, the set $\{\omega \mid X(\omega) \in I\}$ of elements $\omega$ of $\Omega$ where the range $X$ belongs to $I$ is an event. The law of probability of $X$ is the measurement which assigns $p(\{\omega \mid X(\omega) \in I\})$ to the interval $I$; the expected value of $X$ is defined as the integral of $X$ with respect to probability $p$ or the integral of the function $x$ with respect to the law of $X$. A theory of *stochastic processes* was successfully developed, similar to Brownian motion. Such a process is defined by the datum of a family $(X_t)_T$ of random variables; interpreting the index $t$ as a time, $X$ is the random result of a physical measurement at the point of time $t$. In the 1950s, the American mathematicians Joseph Doob and G. Hunt interpreted potential theory in terms of stochastic processes. Subsequently, numerous applications for calculating probabilities in analysis and differential geometry were developed. One example is ergodic theory, which emerged from Boltzmann's ideas on statistical mechanics and involves the study of dynamical systems from the point of view of measurement. Probabilities are also present in many applications in the world of physics, through mathematical statistics.

The solution to Hilbert's fifth problem comes from the theory of topological groups, such a group being a topological space with a law of continuous internal composition, which makes a group where the inverse of an element depends constantly on that element. A Lie group is an analytical variety with a law of analytical composition, which makes it a group. The theory of topological groups was devised in the twentieth century, starting in the 1930s; over the same years, Elie Cartan and Hermann Weyl tackled the global theory of Lie groups (Lie theory being a purely local theory). In 1935, the positive solution to Hilbert's problem was found by John von Neumann and Lev Pontryagin for a finite-

dimensional compact group or a locally compact commutative group, using the linear representation theory of groups. The key tool is the Haar measure which is invariant for translations (e.g. right translations) on the group; the existence of such a measure, which is virtually self-evident in the case of Lie groups, was proven by A. Haar in 1933. A complete family of finite-dimensional irreducible linear representations in a given compact group can then be constructed; the spaces of these representations are formed by the intrinsic functions of certain integral operators on the group. As a result, any neighbourhood of the neutral element in the group contains a sub-group distinguished so that the corresponding quotient is a Lie group; in particular, a connected finite-dimensional locally compact group is a Lie group. Irreducible representations of a locally compact commutative G group are all of dimension 1; these are continuous G homomorphisms in the multiplicative group U of complex numbers with the absolute value 1, known as G *characters*. The G* set of characters of G has a natural group structure, arising from the structure of U, and a topology which makes it a locally compact group referred to as the *dual* group of G; the G group naturally identifies with the dual group of G*. The dual of a compact group is discrete; for example, the dual of U identifies with the additive group Z of integers, its characters being in the form $\chi_n(e^{i\theta}) = e^{in\theta}$ ($n \in$ Z), but the dual of the additive group R of real numbers identifies with R, the characters being in the form $\chi\lambda(x) = e^{i\lambda x}$. This theory meant Pontryagin was able to prove that a locally compact commutative group generated by a compact neighbourhood of its neutral element is a finite product of groups of one of the types U, R, Z, Z/$n$Z. It should be noted that Pontryagin duality provides the natural framework for commutative harmonic analysis, covering the study of the Fourier transformation between the functions over G and the functions over G*.

The general case required other methods, for there are locally compact topological groups without any complete system of linear representations; this was done in 1952 by A. Gleason, Deane Montgomery and Leo Zippin, who proved that a locally compact group that operates in an effective and transitive way on a finite-dimensional locally connected and locally compact space X is a Lie group and that X is a homogenous space in it (and therefore an analytical variety). The central finding is that a locally compact group G where there is a neighbourhood of the neutral element $e$ not containing any sub-group other than $\{e\}$ is a Lie group. The tangent space $e$ is formed for this group using sub-groups with one of the G parameters, i.e. continuous homomorphisms of R in G; if $x$ and $y$ are two such one parameter sub-groups, their sum is defined as the limit, for infinite $m$, of

$$\left( x\left(\frac{t}{m}\right) y\left(\frac{t}{m}\right) \right)^m \quad (t \, \hat{I} \, R).$$

An 'associated' representation of G can then be defined in this tangent space and the kernel of this representation is essentially commutative.

The linear representation theory of Lie groups was a subject for a great deal of research, in particular because of its role in quantum mechanics (representation of the Lorentz group). In 1939, the physicist E. Wigner discovered that irreducible unitary representations could be infinite-dimensional. To this day little is known about the more

general case and the theory has only been properly developed for real reductive groups (Harish Chandra) and for nilpotent groups (A. Kirillov). Coefficients of linear representations are special functions and this theory has been greatly elucidated by the theory of groups.

Algebraic numbers are complex numbers that satisfy an algebraic equation of whole coefficients; the others are called transcendental numbers. Joseph Liouville proved the existence of transcendental numbers in the nineteenth century; excluding Liouville's numbers (which are somewhat artificial), the only transcendental numbers known prior to 1900 were $e$ (Charles Hermite, 1873) and $\pi$ (F. Lindemann, 1882). General methods for proving that certain numbers were transcendental were developed in the twentieth century and helped solve Hilbert's seventh problem in 1934 (Aleksandr Gelfond and Theodor Schneider). These methods related to the properties of certain transcendental functions; it was shown that their values are transcendental numbers when the variable has an algebraic value. They are also based on the approximation properties of irrational numbers using rational numbers ('Diophantine approximations'); the idea is that if the number is considered as algebraic, the approximation cannot be very fast. After the theorems devised by Axel Thue (1909) and Carl Ludwig Siegel (1921, 1929), the best finding of this kind was by K. Roth (1955), stating that where $a$ is algebraic and $\varepsilon > 0$, there can only be a finite number of couples $(p,q)$ of whole prime numbers between them, so that

$$\left| \alpha - \frac{p}{q} \right| \leq q^{-2-\varepsilon}.$$

Such findings have applications for Diophantine equations; Siegel was thus able to prove that an equation $f(x,y) = 0$ of the kind $\geq 1$ can have only a finite number of solutions in whole numbers. Interest in transcendental numbers was revived after Alan Baker (1966) succeeded in lowering the bounds of linear combinations with algebraic coefficients of logarithms of algebraic numbers.

Riemann's hypothesis, which is Hilbert's eighth problem, states that the *zeta* function, defined for

$$\mathrm{Re}\, s > 1 \text{ as } z\,(s) = \sum_{n \geq 1} \frac{1}{n^s},$$

does not vanish for $\mathrm{Re}\, s > 0$, when on the 'critical' right $\mathrm{Im}\, s =$ ; if this property is true, it can be used to show, as Riemann had observed, the order of magnitude of the difference between the function of distribution of prime numbers and the integral logarithm function equivalent to it. In 1942, the Norwegian mathematician Atle Selberg showed that, whenever $T > 0$, the proportion of zeros $s$ of $\zeta$ so that $|\mathrm{Im}\, s| \leq T$ which are on the critical right remains higher at a certain number slightly smaller than 1; if Riemann's hypothesis is true, this proportion must be equal to 1. It is also known that for any zero $s = \sigma + it$ with $t > 0$, $\sigma \leq 1 - A(\log t)^{-2/3}$ when $A$ is a positive constant (I. M. Vinogradov and N. M. Korobov, 1958). Computer calculations, which can be used to reach a very large number of zeros of $\zeta$, still confirm Riemann's hypothesis, but no path has been found for attacking the proof and the Clay Foundation has acclaimed it as one of the seven great mathematical problems for the twenty-first century.

However, proof has been given of the analogy with Riemann's hypothesis for zeta functions attached to algebraic varieties over finite fields. The situation is then simpler as these functions are rational in relation to the variable $q^{-s}$, where $q$ is the number of elements in the base field. These functions are found in evaluating the number of polynomial congruence solutions; the first were submitted by Emil Artin (1924) for congruences expressed as $y^2 \equiv P(x)$ (mod.$p$) ($P$ being a polynomial of whole coefficients, $p$ a prime number), defining a hyperelliptic curve over the field with $p$ elements. In 1935, Helmut Hasse proved Riemann's hypothesis for the $\zeta$ function of type 1 curves (elliptic curves) over a finite field, then André Weil (1940, 1948) proved it for any curve. To do so, he had to devise abstract algebraic geometry (1946), where the coordinates could be in any commutative field and no longer in the field of complex numbers. In 1949, Weil developed his famous conjectures on the zeta function of an any-dimensional algebraic variety over a finite field (rationality, functional equation, Riemann's hypothesis). These conjectures, interpreted in terms of cohomology of algebraic varieties, boosted algebraic geometry, in particular from 1957 on, with Alexandre Grothendieck, who successfully developed the cohomological theory that was to lead on to the proof of Weil's conjectures by Pierre Deligne in 1973.

According to the law of quadratic reciprocity, if $p$ and $q$ are odd prime numbers which are not both in the form $4n+3$, the properties '$p$ is congruent to a square mod.$q$' and '$q$ is congruent to a square mod.$p$' are equivalent; where $p$ and $q$ are in the form $4n+3$, if one of the two properties is true, the other is false. In the nineteenth century, analogous laws for residues of the powers of 4 and 3 (Jacobi, Eisenstein) then $\ell$ odd prime (Kummer) were found. In his ninth problem, Hilbert calls for a more general law, where the field of rational numbers is replaced by a field of algebraic numbers, prime numbers being replaced by ideal primes. This law was proven by T. Takagi (1920), Hasse (1926, 1930) and Artin (1928) as part *class field* theory, studying the structure of finite Abelian extensions of a given number field $k$ and the decomposition of ideal primes in $k$ in such an extension. Hilbert himself had transposed the law of quadratic reciprocity using 'local' symbols

$$\left( \frac{a,b}{p} \right),$$

equal to 1 or $-1$ depending on whether the congruences $x^2 - ay^2 \equiv b$ (mod.$p^k$) have or do not have a solution for any $k$; a symbol has to be added

$$\left( \frac{a,b}{\infty} \right)$$

equal to 1 unless $a$ and $b$ are negative, in which case it is equal to $-1$. The reciprocity law is then expressed by stating that the product of

$$\left( \frac{a,b}{p} \right)$$

for all prime numbers $p$ and for the 'point at infinity' $p = \infty$ is equal to 1. Generalization consists of defining symbols

$$\left( \frac{a,b}{\mathrm{P}} \right)_\ell$$

for all the 'points' p of a number field $k$; these points are the embeddings of $k$ as a sub-field in a non-discrete complete valued field: there is an infinite number of these assigned to the ideal primes of $k$ and a finite number of them which

embed $k$ into R or C. Unfortunately there is no complete knowledge explaining these local symbols.

The eleventh problem again makes use of these local methods, for the theory of quadratic forms over a number field $k$ is based on the Hasse-Minkowski principle which states that, for a form $f$ to be transformed into a form $g$ with variables introduced by linear substitution (representing $g$ by $f$), it is enough for it to be on each local completion $k_p$ of $k$. But, for forms with whole coefficients, local conditions are not sufficient for concluding that the transformation can be done from $f$ to $g$ by linear substitution with whole coefficients. Two forms, $f$ and $f'$, are said to belong to the same type if, at every point $p$, it is possible to go from one to the other by invertible linear substitution with coefficients in the ring of whole numbers of $k_p$; each type contains a finite number of classes of forms equivalent on the ring of whole numbers of $k$. Siegel (1935, 1937) showed how to calculate the average of the number of representations of a form $g$ by the forms of the type to which $f$ belongs as a product of relative local factors at different points. Subsequently, T. Tamagawa and M. Kneser (1961) interpreted these formulae using the adele ring of the orthogonal group G. This is the sub-group $G_A$ of the product

$$\prod_p G(k_p)$$

formed by the elements for which all the components, except for a finite number of them, are whole; this sub-group has a topology which makes it a locally compact group into which $G(k)$ is embedded as a discrete sub-group. The quotient $G_A/G(k)$ is finite in volume for an invariant measure, and Siegel's formula is equivalent to the calculation of this volume.

In the mid-nineteenth century, Leopold Kronecker realized that any Abelian extension of the field Q of rational numbers is contained in an extension generated by the roots of the unit of the form $e^{2\pi i/n}$. He had conjectured an analogous expression for the Abelian extensions of an imaginary quadratic field $k$, these being contained within extensions generated by values of elliptic functions with complex multiplication in $k$ and by the corresponding values of the modular invariant. This conjecture was proven by Takagi (1920). Hilbert's twelfth problem was to find functions able to give a similar description of Abelian extensions for any number field. Certain extensions of an imaginary quadratic field over a totally real number field can be described using complex multiplication of Abelian varieties, these being analogs, on a higher dimension, of elliptic curves (Goro Shimura and Yutaka Taniyama), but there is no hope of finding all Abelian extensions this way. A more interesting path seems to be in the programme devised by R. Langlands in 1967. This was a generalization of the work by E. Hecke showing a correspondence between automorphic forms (one variable) and the Dirichlet series. Langlands defined generalized automorphic forms associated with a reductive linear algebraic group G defined over a number field $k$ considering the space $E$ of square integrable functions on the quotient of $G_A$ by $G(k)$. A parallel theory exists where $k$ is an algebraic function field in one variable over a finite field. The subject is the natural representation of G in the subspace $E_0$ of 'parabolic forms', and each irreducible representation $\rho$ of G occurring in this representation is associated with a function L($\rho$,$s$), an infinite product of local factors associated with points in $k$;

Langlands conjectured that this could be used to calculate all the Dirichlet series occurring in number theory and algebraic geometry. Where G is the multiplicative group $GL_1$, Langlands' conjecture is equivalent to Artin's law of reciprocity. The general case was recently proved by Laurent Lafforgue for the case of a function field. For a number field, we are still a long way from having complete results, which would extend the theory of class fields to non-Abelian cases. The proof of Fermat's last theorem by Andrew Wiles (1994) consists of proving a Taniyama-Weil conjecture on elliptic curves as a consequence of Langlands' conjecture.

In a sample of some ten cases, it has been seen that the solving of Hilbert's problems inspired research throughout the twentieth century. But some theories developed independently of these problems, for example algebraic topology, the theory of partial derivative equations, the theory of dynamical systems and differential geometry. In these, as in previous cases, the mid-1930s can be seen as a turning point; this was a time when difficulties had built up, forcing mathematicians to devise new theoretical tools for general application, reviving work on the very foundations of a number of sectors.

This was the case for logic, with the theory of models and the specific notion of computability, and for probability with Kolmogorov's axiomatics and the theory of stochastic processes. The theory of linear representations of groups and the theory of partial derivative equations led to the development of *functional analysis*, where objects are infinite-dimensional spaces of functions, which may conceivably be generalized. In particular, the study of hyperbolic equations imposed the idea of generalized solutions, no longer seen necessarily as functions (Sergei Sobolev, 1936, Laurent Schwartz 1951); this was how the theory of *distributions* was developed. Algebraic topology, which endeavours to classify topological spaces using invariants that are algebraic in nature, was one of the dominant theories in the twentieth century; it became increasingly algebraic in the 1930s and developed to the point of devising auxiliary techniques such as homological algebra (a type of extension of linear algebra), the theory of categories (Samuel Eilenberg and S. MacLane, 1942) and sheaf theory (Jean Leray, 1945–46). Sheaf theory provided the basis for the revival of algebraic geometry led by Jean-Pierre Serre (1955) and Grothendieck. Algebraic geometry and number theory also stimulated the development of commutative algebra.

This period of renewed interest ended by the mid-1960s, by which time a certain number of problems previously beyond reach could be successfully tackled. The years from 1935 to 1965 were marked by the activity of N. Bourbaki (a collective name for a group of French mathematicians) working on the most fundamental aspects of mathematics in a unified approach, based on Hilbert's axiomatic method and the concept of mathematical structure. The period was also a time when mathematics and physics moved apart, in contrast with the 1920s when physicists and mathematicians joined forces, working closely together on general relativity and quantum mechanics. The theory of general relativity revived interest in research into differential geometry, while quantum mechanics provided an opportunity for developing the theory of the algebra of operators on a Hilbert space; in fact, mathematicians such as Weyl and Von Neumann did the work of physicists. The symbiosis between physics and mathematics returned in the 1970s and 1980s with the development of the quantum theory of fields, gauge theories,

supersymmetry, non-commutative geometry and quantum groups. One example can be seen with the 1990 Fields medal, awarded to the American physicist Edgar Witten.

Outside of fundamental physics, mathematics can also be found in such applications as celestial mechanics, elasticity, hydrodynamics, medical imaging, oil exploration, cryptography, telephone transmission and information technology. But groups of mathematicians focusing on these applications often see themselves as apart from other mathematicians, thus creating a sociological divide between 'pure mathematics' and 'applied mathematics', which is not based on any fundamental difference in methods. Perhaps the reasons behind this divide should be looked for in the vast expansion of new applications over the war years.

## NEW SUBJECTS AND METHODS IN PHYSICS

Many of the major technical achievements and changes to our knowledge of physics have not been mentioned in previous chapters, even though they have helped transform our everyday lives. Take, for example, plasma physics, or our hopes of finding a way of controlling and using thermonuclear fusion, or developments in statistical mechanics and thermodynamics, relevant not only to phase transitions and critical phenomena, but also to phenomena far from equilibrium. There are numerous applications in chemistry, with illustrations provided by the work of Ilya Prigogine and his school. Another enriching field of study is found in 'everyday' physics, where problems that seem as ordinary as the equilibrium of a pile of sand or the contact between a drop of boiling liquid and a hotplate require ingenious and erudite theoretical explanations. In the field of chemistry, mention should be made of the complex architecture of molecules which, to cite one example, Jean-Marie Lehn shaped to fit multiple applications. And there are many other illustrations of how physics has contributed to our understanding of everyday events.

In the following section we will simply point out some of the problems raised by the new ideas arising from physics: first there is the basically philosophical question of the relationship between physics and mathematical abstractions, which extends to the issue of the dialectics of simplicity and complexity; then there are the changes in the conception of the nature of physical theory arising from the theory of dynamical systems, commonly referred to as the theory of deterministic chaos; and lastly there are various aspects concerning experimental techniques and developments that have occurred in what is now called 'big science'.

### Abstract subjects, mathematically formalized theories, simplicity and complexity

Physics underwent major theoretical changes in the course of the twentieth century, affecting both the definition of the subject of study and the nature of the founding theories and experimental procedures.

From a conceptual and theoretical point of view, physics went through both the relativistic and quantum revolutions, forcing it to rebuild, or rather acquire a different understanding of the concepts of time, space and energy, of the material particle and even of the idea of quantity or magnitude and of a physical system in general. These concepts and quantities were then beyond the grasp of previous 'intuitive' or absolute representations, and their form (expressed in mathematical terms) and content were constituted as functions of phenomena expressed in physical principles governing their relations. These principles are often presented as conditions of invariance applying to the transformations of these quantities, being characteristic of the dynamic laws governing a given domain.

These conceptual and theoretical changes simultaneously transformed our general views on physics, on the definition of its subject area and the development of its theories. One of the most striking features of current conceptions is the increasingly close relationship between physical theories and mathematical formalisms. This interweaving simply highlights a feature in the logical path of previous developments where theoretical physics was built through analysis, with differential and integral calculus for the mechanics of material points and solid state mechanics, and was then extended to partial derivative equations for fluid mechanics and field theory.[80]

With general relativity and quantum theory, *mathematical formalization* became a particularly powerful tool for theoretical work in physics, making it possible to express known or recognized physical properties, both general properties or *physical principles* and quantitative relationships between quantities. The principles (spatio-temporal or internal invariances) had been laid down, and the quantities or magnitudes used to describe the physical systems (e.g. atomic or nuclear states, particles or fields) were already known or had been formulated, so the theory connecting these quantities and guided by the principles was almost entirely deductive.

Theoretical representations of the (quantum) structure of matter have taken this feature to quite an extreme degree. They involve physical magnitudes derived from abstract formulation, devised on the basis of properties of invariance; this is the case, for example, of quantum numbers such as spin, fermion charges or baryonic and leptonic numbers, and the flavours and colours of quarks. The relationships between these quantities determine the more general symmetry properties, which are then raised to the rank of principles and adopted to govern the form of the dynamic theory. This was how gauge invariant theories were formulated for fundamental matter, electroweak and chromodynamic fields. The idea of *invariance* or *symmetry* required these to also be unified at the same time, as developments leading to these theories have shown with great eloquence. So it is that a large part of fundamental physics, the most mathematically formulated part, seems to be moving towards a unified theory.

Underlying this observation is a new version of the idea that mathematics can be used as the most accurate means of expressing the hidden, deep-seated structural link between elements that are part of the same reality. This is no doubt the basic reason for the preferred relationship (although it is actually a relationship in constitution) between physical thought and mathematical thought.

It should be noted, however, that this trend in theoretical physics towards more abstract and mathematical expression has not, despite its fundamental nature, exhausted the representations of matter in its different structural levels. The complexity of these levels, even when reduced in principle to elementary simplicity, does not vanish, but

requires intermediate theoretical concepts and models. Knowledge of the basic constitution of matter (fields and particles), while reconstructing combinations of elements, cannot produce a representation for direct use depicting the complex levels of organization (e.g. nuclear matter inside atomic nuclei, atoms and chemical properties, large sets of molecules and macromolecules, or macroscopic behaviour of matter). Specific theories or models, which can be appropriately handled and are relatively simple, are needed for each level, where the relevant physical quantities are only connected in an increasingly remote way to the quantities at the most 'fundamental' level. This observation applies for both conceptual and practical reasons.

The connection between the representations of the different levels is the task for research in the diverse branches of physics, chemistry and other disciplines. But the epistemological questions it raises are related to the general issue of reducing something to its elementary level and of constituting 'complex' levels, or 'emerging' levels. When moving from the level seen as fundamental to a structural or organizational level of greater complexity, consideration must be given to properties which appear only at this level and are expressed by specific 'emerging' quantities (e.g. the concept of valence in chemistry). Here it is more a case of tension developing between two approaches, each with a different orientation, yet each one essential, rather than a case of inherent duality. New interdisciplinary approaches are needed to explore the dynamics of knowledge in these bordering regions.

## Dynamic systems and deterministic chaos

Since the 1970s, the study of dynamic systems, previously relegated to a relatively minor branch of mathematics, has developed into a discipline that now stands as one of the most important, not only in mathematical physics but also in theoretical and experimental physics. The central idea goes back to the mathematical research of Henri Poincaré in dynamics, working on the qualitative theory of differential equations that developed from his study of the three-body problem in astronomy (1889). One of the solutions to these totally deterministic equations was so complicated and unusual for a certain configuration that it seemed to be random. Yet it was possible, without writing out exact solutions, to describe the nature of the solutions, i.e. their structural behaviour, with stable or unstable equilibrium. Poincaré then introduced the 'limit cycle' concept.

Considering therefore that the fundamental problem for dynamics was to find quasi-periodic solutions of systems and to discover how they behaved, Poincaré devised, to quote the Swedish Academy, 'a new way of thinking'. He had shown for the first time that, in perfectly determined events, 'a very small cause, which escapes us, determines a considerable effect'. At a certain point in time, a tiny element of uncertainty on the initial conditions makes it impossible to produce any accurate prediction.

Around 1892, Alexander M. Lyapunov had been conducting work with a similar focus on the stability of motion. Between 1930 and 1960, a school of applied mathematics and mathematical physics developed in the Soviet Union. Its focus was non-linear dynamic systems and stochastic processes. Problems in the regulation of

machines and radio techniques (with electromagnetic waves) focused interest on non-linear oscillations, working on systems of conservation and their qualitative behaviour, and also on dissipative systems.

A. A. Andronov, one of the pioneers of the Russian school of mathematics in dynamic systems, studied the findings of Poincaré and Lyapunov and applied them to physical situations in the domain of dissipative physical systems, developing a general theory of non-linear oscillations based on the idea of a self-oscillating system and bifurcations. His first paper on 'Poincaré's limit cycles and self-sustained oscillations' was published in 1929 by the Académie des Sciences in Paris. Applications were relevant to many fields, including acoustics, radiophysics, reaction chemistry and even biology. In 1937, with his fellow authors A. A. Vitt and S. E. Khaïkin, he published his landmark work, *Theory of Vibration*.

Other prominent members of this school were L. I. Mandelstam, N. S. Krylov and N. N. Bogoliubov, who developed non-linear physics, and the great mathematician Andrei N. Kolmogorov, who was also known for his outstanding work on the theory and applications of probability. In 1940, he had also tackled turbulence phenomena and later, in 1950, dynamic systems.

In the United States, George David Birkhoff, author of *Dynamical Systems* (1927), and his student G. M. Morse, worked on the development of 'topological dynamics', while Salomon Lifschitz explored the findings of the pioneers in the Russian school and, in the late 1940s, pursued his study of differential equations in dynamics.

In the course of the 1960s, work by Stephen Smale and Valentin I. Arnold investigating differentiable dynamical systems drew attention to the findings of the Soviet school and marked the beginning of international interest in these problems. In 1963, the meteorologist Edward Lorenz used a computer to calculate predictions with a simplified mathematical model of convection currents in the atmosphere and found the same considerable effect amplifying small differences in the initial condition that had been noted by Poincaré: small causes, such as localized storms or the flutter of a butterfly's wings, can produce substantial effects on weather on the scale of the hemisphere, or of the entire planet. The sensitivity of such totally deterministic systems to tiny changes in the initial conditions meant it was impossible to predict their ultimate behaviour: the term 'chaos' was suggested soon after to describe this situation, which is in fact extremely frequent. In the 1970s, Lorenz applied his ideas to the biology of populations and it was subsequently noted that chaotic behaviour patterns were to be found in the most diverse areas, e.g. the behaviour of the solar system, the operation of lasers, the evolution of ecosystems and the kinetics of chemical reactions.

In 1971, David Ruelle and Floris Takens showed that chaotic behaviour is not intrinsically linked to a large number of parameters, and introduced the concept of the 'strange attractor' to describe the characteristic curve of the parameter of a chaotic system that is actually the final stages possible in dissipative systems. This concept was then moved to the centre of the theory as a substitute for the parameters: the attractor is the hidden structure concealed by the apparent chaos of the trajectories. In doing so, the local focus becomes global, details give way to generic considerations and to the type of stability of the configurations. Proof could be found for these attractors,

first through digital simulation, then in laboratory conditions with, for example, hydrodynamic phenomena (Pierre Bergé, one of the pioneers in the physics of chaos as studied from the phenomenological viewpoint).

For a dynamic system to be chaotic, it must comply with certain conditions: complex systems with a large number of parameters need to be described using well-established equations (e.g. the future orbit of the Earth), or otherwise to have a small number of parameters (e.g. certain chemical reactions). In biology and economics, it is more difficult to establish whether the systems are genuinely chaotic because of the uncertain nature of their mathematical modelling. Whatever the case may be, chaos can be a powerful theoretical tool for studying new properties and behaviour patterns.

## Experimental methods and techniques in the era of 'big science'

In certain areas of physics, such as nuclear and solid-state physics, a close link was established between the development of scientific research and the development of industry after the Second World War. The Manhattan Project for building the first atomic bomb is a good example.[81] This seems to have been the signal for change in research in these and other disciplines. The change has affected the way researchers work, the methods and techniques used for experimentation, relations with public authorities, and the organization of research, which is now performed by groups and teams working in large laboratories where researchers and engineers collaborate closely, inventing and using original, complex, high-precision instruments.

These are large and costly machines that have been built using the most advanced techniques, such as high vacuums, superconductivity, electronics and computer processing, often developed in research laboratories well before being adopted for industrial use, and providing just as many offshoots for use in other domains. They are increasingly being used by groups built around international partnerships; this is the case of large particle accelerators, major observatories and space laboratories.

Subatomic physics and astrophysics are two typical examples of this form of science that originated in the second half of the twentieth century and which has been dubbed 'big science'. The term refers to science requiring 'big' resources – financial, material, technological and organizational – and which is considerably different from scientific research in the past, which was conducted more on an individual basis. In research nowadays, there is a close link between the development of theoretical ideas and the conducting of experiments related to technical advances it has often helped bring about; this is the case for the technology used in accelerators for nuclear physics[82] and particle physics.[83] These are needed to generate and accelerate intense beams of nuclei and particles or radiation of all kinds,[84] to develop various detectors for precision analysis of reaction products,[85] and for on-line processing of complex data and fine statistics using huge calculators, and for shape recognition and high-definition tracking. These analytical techniques originally devised for particle physics have also been adapted for collecting data in the field of astrophysics.

Interaction between leading-edge technology and experimental research is also common practice in domains other than those cited above: e.g. in very low-temperature technology and the cooling of atoms, for Bose-Einstein condensation, plus in overcoming the challenges in the planned use of devices for detecting gravity waves. Generally, in order to find proof of phenomena of a new kind deduced from the theoretical advances of physics, it is necessary to make the corresponding experimental and technical advances.

Another noteworthy feature is the 'plasticity' of the applications of modern physics, with equipment developed to gain knowledge of fundamental physical phenomena subsequently being used for research or applications in quite different domains, in physics, biology and medicine. One example is synchrotron radiation, with electron accelerator rings producing beams as intense and finely defined as lasers, covering a broad range from gamma and X-rays to visible light, and used both to study solid-state structure and for applications in biology and medicine. A parallel can be seen with X-rays and radioactivity, which were used almost immediately after they were discovered to observe the inside of the human body and provide medical treatment.

A very long list of the uses and applications could be drawn up, but here only a few examples will be highlighted: NMR spectroscopy in chemistry; dating techniques using radioactive elements, first with radiocarbon or carbon-14; the cobalt bomb, with induced radioactivity, used to treat cancerous tumours; advances in brain imaging using radioactive elements, and most importantly the positron camera for extremely accurate localization of damaged areas, which has recently led to great steps forward in neurophysiology; and proportional multi-wire chambers with highly accurate localization capacity, with prospects for diverse applications beyond the simple detection of elementary particles, ranging from medicine to fraud detection for customs officers inspecting goods.

Large telescopes must also be cited. Astronomy and astrophysics are now rivalling subatomic physics with the large machines used for fundamental research. In this field, astronomy already had the experience and a long tradition of large, classical science observatories (e.g. Maragha in Iran, dating from the twelfth century, and the larger-scale copy built in Jaipur, India, in the eighteenth century; the Uranienburg observatory in Denmark built by Tycho Brahe in the seventeenth century; observation using telescopes, and the huge mirror telescopes made by William Herschel towards the end of the eighteenth century). In the late twentieth century large land and space telescopes were constructed, with resolution capacity for viewing celestial bodies in remote systems and the very furthest galaxies – those first formed on the bounds of the visible universe at approximately 15 billion light years.

Of the different land telescopes, special mention should be made of the 10-meter double telescope in Hawaii, named Keck. It is positioned on the top of Mauna Kea volcano, where it can observe the sky of the northern hemisphere. In 1997 and 1998 it spotted two very primitive galaxies on the bounds of the Universe, at some 13 billion light years. There is also the European Southern Observatory (ESO) for the southern hemisphere. Located in the Andes in Chile, it offers outstanding visual acuity with an array of four 8.2 metre telescopes, and a Very Large Telescope (VLT) installed in 2001.[86] Of the different satellite-borne instruments, the Hubble Space Telescope will go down in history, and rightly so, for the extraordinary contribution it has made to our knowledge of celestial objects, distant

galaxies and extra-solar planets. Freed from the constraints in the Earth's atmosphere, it was able to explore regions and phenomena inaccessible to land observatories (e.g. phenomena which can only be seen using infrared light[87]). Many other observatories have giant telescopes, either on land or satellite-borne, and will, over the early years of the twenty-first century, continue this observational exploration of the Universe. (Hubble's successor, NGST,[88] will not orbit around the Earth, but around the Sun.)

## BIOLOGY

### Fundamental changes in biology

Biology is seen today as a group of different disciplines, with quite distinct subjects and levels of observation. One approach classifies these disciplines according to the scale used to study phenomena in living organisms.

An initial group is composed of molecular genetics, biochemistry and cell biology. These three disciplines analyse the complexity of living organisms at the macromolecular level. Each one has its specificity: genetics studies genes and their mechanisms of action; biochemistry focuses on a structural study of DNA and more importantly of proteins, the second essential constituent of living organisms; while cell biology investigates intra-cellular organization and movements of macromolecules within that structure. The term 'molecular biology' is often used to refer to part or all of the experiments conducted in these three disciplines (as well as other biological disciplines, as mentioned below) and which do not fit into any established discipline, but are related to a certain view of living phenomena and the desire to explain all the properties and functioning of living beings by studying their macromolecules.

The second group of disciplines studies the organism as a whole, either describing its properties and classifying it on the scale of living organisms (zoology and botany), or describing the way it functions (physiology). Physiology also encompasses a number of specialized fields dealing with one or another of the major functions of living organisms (e.g. endocrinology, immunology and neurophysiology). There are obvious links between physiology and medicine, and the same applies to other disciplines dealing with micro-organisms, many of which are pathogens affecting humans (bacteriology, virology and parasitology).

The third group of biological disciplines includes areas covering all living beings, to study either their social behaviour (ethology), their complex interactions with the environment (ecology), or the evolution of their genetic make-up (population genetics).

This discipline-based presentation does not reflect the major changes that each of these disciplines has experienced over the past century, nor the successive waves of unification which have recognized the special significance of biology in the early twenty-first century (see the above section on Molecular Biology for the description of these changes).

### A far-reaching development in biological disciplines

In 1914, with Thomas H. Morgan's first studies of *Drosophila*, genetics discovered the organism that would not only establish the discipline, but also produce findings

confirming the link between genes and chromosomes, making it possible to draw up the first genetic maps. But almost twenty years more were needed for these genetic maps to merge with the physical maps of chromosomes. The slow process of objectification – of 'reification' of genes – was only fully achieved when the genes were identified with the DNA molecule, whose structure (the double helix) was discovered in 1953 by J. D. Watson and F. Crick. This was the beginning of molecular genetics, which in the following years detailed the mechanisms of genetic action. By the end of the twentieth century, genetics had become a powerful science. Thanks in particular to the techniques of genetic engineering, it had all the tools needed to move from the genetic trait to the gene, to the DNA molecule, and then back to the traits, and to modify them. Genetics is an important science with an increasing number of medical applications, but it is also a science that triggers anxiety in the face of apparent threats to individual freedom. Can the predictive medicine of tomorrow both define our genetic limits and predict our future?

Since 1914, biochemistry has also seen far-reaching changes. The only molecules of living organisms available to biologists in 1914 were small metabolism molecules. Proteins were still poorly characterized and their structure was unknown. The development of such technologies as X-ray diffraction and nuclear magnetic resonance has permitted biochemistry to determine, with great accuracy, the structure of essential biological macromolecules, proteins and nucleic acids. Cell biology reached its peak by the 1950s with electronic microscopes, which gradually revealed the complexity of living cells. This advance was only achieved through close cooperation with biochemistry and later, from the 1970s on, with molecular biology. Today, cell biology is one of the most active disciplines as biologists increasingly integrate the cell level into all molecular observations of living organisms.

Other disciplines have also changed, first with the biochemical revolution, then with the molecular revolution. One example is endocrinology, which examines the mechanisms by which hormones act; the mechanism can only by grasped by determining the structure of hormones themselves, and characterizing the receptors they bind to and the paths that transmit the information from the receptor to the cell nucleus. In most cases any fluctuation in the amount of hormone causes a change in the activity of the genes; this activity can only be understood using the tools and knowledge provided by molecular genetics.

All branches of physiology have also been 'molecularized' to varying degrees, e.g. immunology and neurophysiology. Nevertheless, physiology has retained both its specific level for describing living phenomena and its own techniques, such as medical imaging. Both have contributed greatly to advances in our understanding of the brain. Bacteriology and virology have been as molecularized as physiology (or perhaps even more so). The molecule is the level targeted to characterize the interaction between the pathogenic organism and the host; by using molecular tools, we gain an understanding of the nature of pathogenic micro-organisms.

Those sciences – like zoology and botany – that describe and classify organisms, have also changed considerably. In the 1960s, their fate seemed threatened by the 'modern biology' boom that included genetics, biochemistry and molecular biology. Yet it gradually became apparent that no

study, not even molecular studies, could disregard the findings of these other disciplines, and they too have gained from the contributions of biochemistry and molecular biology. Ever since Darwin, the description and classification of living beings has been based on the establishment of polygenic relationships between these living organisms, following the pattern of evolutionary trees. Morphological criteria were replaced by biochemical criteria, then molecular criteria, which were more neutral but infinitely more fertile.

Certain biological disciplines in the third group also use molecular tools, for example, population genetics, which has followed and used the advances of the parent discipline, or ecology.

The most characteristic feature of contemporary biology is the deep-seated unity that has developed around the tools and concepts of molecular biology. The first stage occurred in the 1930s when zoology embraced Darwin's theory of evolution and population genetics. It was not an easy marriage, as was seen in the thirty years needed for the full merger, which was given the name of neo-Darwinism. Darwinians initially believed that the variations on which natural selection operated were small in amplitude, while geneticists, who dubbed these variations mutations, considered them, from the very earliest stages of the discipline, to be large and important. Only the mathematical tools of population geneticists managed to convince geneticists that tiny variations could, under constant and long-lasting pressure, produce major modifications. Neo-Darwinism has changed enormously since it first appeared, although, for many years, the growth of molecular biology had little effect on it. Very slowly, molecular biology provided the tools needed to track the molecular evolution of living beings; and it has only been in recent years, with the isolation of development genes (homeotic genes being the first ones discovered and still the most famous) that molecular biologists have 'handed over' to evolutionary specialists the genes presenting variations in structure and function so essential to the understanding of the evolution of living beings. With additional influence from the neutralist theory put forth by the Japanese geneticist Kimura, neo-Darwinism is changing greatly, although its basic principles have not been challenged. It is losing the 'Pangloss' element, by which an adaptive value is attributed to every variation surviving throughout evolution, and is becoming more attentive to genetic (or other) constraints restricting the diversity of living organisms. Neo-Darwinism takes into consideration recently discovered mechanisms, which, in living beings, modulate genetic variability as a function of environmental conditions. The synthesis of theories of evolution, development biology, molecular biology and cell biology will probably be one of the objectives and the success stories for biology in the twenty-first century.

## THE STRUCTURE AND DYNAMICS OF THE EARTH

This section looks at the different advances in geology and geophysics, and focuses on points related to the structure and dynamics of the internal movements of the Earth. By the late nineteenth century, scientists had come to accept that the Earth was configured in successive concentric layers. The twentieth century contributed to our knowledge about the chronology of various periods (the 'ages of the Earth') and saw, by the 1960s, the development of a genuine theory of dynamics for the movements of the Earth's crust and mantle, called plate tectonics.

### The age of the Earth

In the late nineteenth century, estimates of the Earth's age were based on conventional physics measuring heat exchanges and heat losses (see the calculations by the physicist, William Thomson-Kelvin): considering that the crust of the Earth had been cooling down from a point of initial heat, the estimate was only around 100 million years. New data about radioactivity led to revisions of these under-estimates, suggesting the idea of a source of energy within the Earth in the natural radioactivity of rocks. A more realistic evaluation of geological times was made in 1917, by studying the quantity of helium released as a product of uranium decay. Radio-dating techniques were then improved using various radioisotopes such as argon, potassium-40 and, after the Second World War, carbon-14.

Generally speaking, developments in geology have always been highly dependent on advances in related fields, such as the chemical analysis of rocks, mineralogy, palaeontology, plus geophysics and geochemistry, which all made great strides in the course of the twentieth century.

### From continental drift to the theory of plate tectonics

The greatest step forward in Earth sciences has been the advent of *plate tectonics*. This was a revolutionary discovery because it showed a mobile instead of a fixed Earth, while providing a mechanism for its movements and reorganizing the most diverse elements of knowledge around the dynamics of transformations in the Earth's crust – with continental shifts, seismic activity and new mountain ranges forming.

This theoretical revolution, backed by many observations including exploration of the ocean floor, substantiated the 'old' hypothesis of the *continental drift* already formulated by Alfred Wegener in 1912. Wegener suggested that the continents we know today originally came from a single, southern pro-continent, *Pangaea*, that split into parts that migrated across the mantle over a period of hundreds of millions of years.[89] Substantiating his theory, Wegener argued that there were morphological properties such as the coastal profiles of the continents that seemed to fit together, e.g. the Brazilian and West African coasts, and that even though the ocean extends for 4,000 kilometres between the two, they share numerous geological, palaeontological and palaeoclimatic features.

Because no dynamic cause could be found to account for the drift, and given the conservative attitude of most geologists of the time, who were unwilling to abandon the idea of a fixed Earth, Wegener's theory attracted only marginal interest before 1960.

However, topographic and geological studies of the oceans conducted in the 1950s showed that their sedimentation was recent and that they shared an underwater mountain range, i.e. ridges or mid-ocean *rifts*. Around 1960, Harry Hess proposed the idea that the ocean floors were

spreading with convection currents and changing the mantle. Seismology, measurements of magnetic anomalies caused by the appearance of lava beneath sedimentary layers, plus palaeomagnetic data (studying time-related variations in the magnetism of rocks) showed there had been inversions in terrestrial magnetism and magnetic poles. All these findings changed views and perspectives on the dynamics of the Earth's crust and led back to the continental drift hypothesis. The idea was revived and transformed into the now universally accepted theory of plate tectonics for ocean and continental plates.

J. Tuzo Wilson presented the concepts of plates and transform faults in 1963, while Jason W. Organ, Dan MacKenzie and Xavier Le Pichon described the mechanism of plate tectonics (1967–68). They argued that the Earth's crust comprises rigid plates shifting in relation to one another, and that new plates, forming as a result of volcanic activity along the ridges, eventually take the place of the old ones. Ocean plates go down deep beneath the continental plates where they collide with one another, causing mountains to rise up; the Himalayas emerged when the plates of India and Asia collided, and the Alps were formed from the collision of the African and European plates. This theory, which accounted so coherently for changing geological and geophysical phenomena, produced predictions that could be verified by observation.

Plate tectonics therefore enabled scientists to reconstitute the past movements of the Earth's crust as a vast series of fragmentations, slides, shifts, turnings and collisions of continental masses occurring from the force of the spreading oceans. A primitive supercontinent named *Rodinia* may have been the beginning of today's continents: it formed some 1,200 million years ago (mya), then broke up into fragments that gathered to form two megacontinents, *Laurasia* in the north and *Gondwana* in the south. *Gondwana* was formed 600 million years ago, and between 390 mya and 210 mya merged with the *Pangaea* supercontinent which formed as an aggregate of all the continents and was surrounded by a single ocean named *Panthalassa*. After Pangaea split up, Gondwana broke up again, circa 170 mya, with the opening up of the Atlantic, Indian and Antarctic oceans, producing the southern sub-continents: Africa, South America, India, Australia and Antarctica.

### Earth sciences and planetology

All sciences related to the properties of the Earth, such as meteorology, oceanography, geology, geochemistry and geophysics, seismology, volcanology and terrestrial magnetism, have gradually moved closer together over the twentieth century to form a synthetic perspective that views phenomena in a coherent relationship governed by the dynamics of the planet Earth. These disciplines have been grouped together in the field now known as earth sciences.

Another development occurring in the final decades of the twentieth century was the interaction of the Earth with space. Knowledge of other planets in the solar system plus systematic exploration through space missions meant comparisons could be made; it became possible to study the composition of other planets (particularly the rocky planets such as Mars, Venus and Mercury, not to mention Earth

and its satellite, the Moon). Earth sciences were thus extended to include planetology. Recently acquired understanding about the impact of celestial bodies in collision has shown how important planetary dynamics is. These sciences and planetology in turn now belong to the much broader group of disciplines referred to as earth sciences and sciences of the Universe.

The history of the Earth's formation also falls within the scope of astronomy, which has provided data on the age of rocks and calculated that the Earth and other bodies in the solar system are the same age, i.e. 4.5 billion years. The Earth and the other bodies in the solar system were formed from the sole impact of universal gravitation, starting from a cloud of gas and dust released from the explosion of a star (supernova), and ending up as part of a process that generated everything from the nuclei of the atoms in chemical elements, right down to the heaviest elements such as iron and uranium.

As for the astronomic and geological histories of the Earth, these disciplines have evolved into a different kind of natural history, the history of the biosphere, discussed below.

## RESEARCH ON THE ORIGINS OF LIFE

While the human race, with its diverse cultures, has always been interested in its origins and in the creation of the surrounding cosmos, the tale has usually been recounted in legends and myths in poetic and supernatural terms. The question of origins has only gradually become a subject for scientific exploration, and even this has occurred in quite different forms, depending on whether it deals with the origins of the human species (human palaeontology), the origins of the Universe (a very recent focus for science, dating from the cosmology of the expanding Universe), or the origins of life. For the origins of life, a problem arises in the formulation and indeed the definition of the term 'life'. No scientifically satisfactory definition existed until molecular biology advanced one during the second half of the twentieth century. The science of the origins of life has now achieved legitimacy and been given its own name: exobiology. The notion of a 'fixed Earth' has been abandoned, and new issues are becoming the subject of modern scientific research.

By objectifying nature, humans have grasped both their distance from nature and the inclusion of humans in this world as an element of nature. The twentieth century has thus completed the movement away from the single centre that characterized the beginnings of modern science: not only were humans and their habitat no longer the centre of the Universe, but nothing in the Universe remained fixed and established once and for all, be it living forms, the Earth, or the cosmos. Everything was movement and change.

Human beings have reached an unprecedented degree of awareness that life on Earth is merely 'a flash in the night of the Universe'; yet despite their precarious natural situation, they continue their questionings, seeking answers and meanings that may help them transcend the situation. While many of these questions have moved into the realms of science, they have nonetheless retained some of their metaphysical force, and here they may also coincide with the very why and wherefore of science itself.

## The history of life on Earth and the origins of the human species

The history of life on Earth has now been given its timeline: the oldest fossil evidence sets the beginning shortly after the formation of the Earth and solar system 4.5 billion years ago. The first bacteria appeared approximately 3.5 billion years ago, the first *eukaryotes* (cells with a true nucleus) approximately 1.5 billion years ago, and the colonization of continents by plants and animals, with animals acquiring lungs and limbs, began 500 million years ago (the first terrestrial plants circa 435 mya, the first reptiles 345 mya and the first mammals 225 mya). Mammals became dominant once dinosaurs had become extinct after the sudden and dramatic climate changes that started circa 60 mya.[90] Placental mammals first appeared circa 100 mya, then primates circa 70 mya (with, *inter alia*, a larger brain and smaller face, opposable thumb and developed eyesight), and apes in Africa and South America circa 40 mya. *Oreopithecus*, circa 15 mya, walked on two legs, having acquired the biped gait in response to ecological pressure. *Ramapithecus*, a small primate that may have used tools, was present from 20 mya to 7 mya in the Old World (Europe, Africa, Asia), and is possibly an ancestor of the *hominid* lineage.

The human species appeared more recently, although much earlier than was believed at the turn of the twentieth century: approximately 3 million years ago. Many discoveries in the field of palaeontology have been decisive and contributed to the considerable progress made in improving our understanding of the origins of the human race; these advances came about with the transdisciplinary approach in the different fields of natural human sciences: i.e. human palaeontology (or palaeoanthropology), anthropology, ethnology, prehistory, and the use of techniques developed by exact sciences such as physics and chemistry. With improvements in methods used to conduct archaeological digs, better dating techniques,[91] and in particular advances in geology and stratigraphy, plus the discovery of many human fossil remains, estimates on past human history have been pushed back in time and have revealed links in the family of primates and, even further back, in the series of animal species. Animal palaeontology and palynology (the study of spores and pollen) were extended and applied to learning more about climatic and ecological contexts, and have led to a better understanding of the lifestyle of the first human beings.

The discovery of *Australopithecus* in southern Africa (Kenya) in 1934 prompted scientists to date the first hominid at one million years ago, but this estimate was revised in 1974 to 3.5 mya, following the discovery of the remains of the slender *Australopithecus* 'Lucy' in the Omo region of the Ethiopian Afar geological basin. *Homo habilis* lived in society, manufactured tools, went from a vegetarian to an omnivorous diet, and was the first species to build dwellings built as proper structures; these are approximately 1.6 million years old. From 1.9 mya to 1.5 mya, *Homo erectus* spread throughout Africa, Asia and Europe. *Pithecanthropus* (with one group, the *Sinanthropus*, discovered in China in the 1930s, and 500,000 years old) was the first to use fire. *Neanderthal man*, first identified in the nineteenth century (1864), buried his dead; he first appeared around 400,000 years ago and disappeared 40,000 years ago, but left no direct descendents, while *Homo sapiens*, who was present in the early Upper Palaeolithic (circa 200,000 years ago), left *Homo sapiens sapiens*, identified through fossil remains of Cro-Magnon man, who decorated caves, was similar to modern humans and lived in the Magdalenian period, the time of the gradual glacial recession of the last Würm ice cap and the slow migration of cold fauna (35,000–10,000 years ago). Human settlement then spread to the five continents, and differentiations between humans became cultural rather than morphological: humans today comprise a single species and, strictly speaking, a single human race, with different groups and crosses. The question of the origin of the human species encompasses both the issue of morphological changes and the question of the growth of the human brain and its capacities, and specifically the development of the power of speech.

## The question of the origins of life

The question of the origins of life has been addressed in science with Darwin's theory of evolution as the breakthrough point on species and their evolution in time. The uniqueness of matter suggests there is continuity in the shift from minerals to living organisms and that life is a property that 'emerges' from the organization of matter. This also raises the question of how to define living organisms, which has only now found an answer through molecular biology. Nevertheless, very fertile and stimulating enquiries were being made well before the 'true' nature of the phenomenon of life was understood.

It was accepted that the origins of life on Earth were connected to the history and origins of the planet. The atoms making up the planet, including those that provide the basic material for living molecules (the main chemical elements: oxygen, hydrogen, carbon, sulphur, phosphorous and also the heavier metals, calcium and iron), were synthesized in a star and subsequently scattered throughout space with the supernova eruption, before reforming as a planet (Earth) in the solar system due to the effects of gravitational pull. The primitive atmosphere of the Earth that later formed with the release of gases from the Earth's mantle also resulted from the bombardment of meteorites, ultraviolet radiation, high natural radioactivity releasing energy, intense earthquake activity, volcanic eruptions and the greenhouse effect resulting from carbon dioxide. These processes also led to the formation of the first oceans. There are doubts as to whether the Earth's first atmosphere was a reducing (methane) or oxidizing one (carbon dioxide), however Earth's present atmosphere is largely the result of the action of living organisms; it can be supposed that, through chlorophyll photosynthesis, microscopic primitive algae produced an abundance of atmospheric oxygen.

Given the openness of living systems, they are subjected in both their constitution and development to the influence of the physical conditions in the outside environment. These conditions have been determining factors in the origins of life itself. It is quite likely that the first living structures developed from interactions between complex molecules in certain chemical and thermodynamic conditions, which polymerized them to form protein chains.

Hypotheses and models were formulated and scenarios devised – using physico-chemical processes starting with inanimate mineral matter – to account for the formation of organic matter and elementary living organisms. Prebiotic

chemistry focuses on the conditions of the primitive mineral Earth, and particularly its oceans and atmospheres, whose chemical constituents were instrumental in the synthesis of increasingly complex organic molecules that eventually gave rise to living micro-organisms.[92]

Efforts to provide physical and chemical explanations to the origins of life prior to breakthroughs on genes and the mechanisms of heredity have given us certain elements that have also been integrated into recent genetic theories on the formation of life.[93] These theories are built on the trilogy of DNA (genetic code), messenger RNA and protein synthesis.

In the 1930s, Alexander Oparin presented a pioneering theory on the natural synthesis of amino acids. He suggested that through 'biochemical metabolism' these would provide an explanation of how life could have appeared in the absence of oxygen, in an atmosphere composed predominantly of methane. The theory was adopted, with a number of variants, by John Haldane ($CO_2$ atmosphere) and John D. Bernal (life produced in oceans or coastal clays).

Genetic theory and molecular biology have given us the means for going beyond a purely physical and chemical framework, by formulating dynamic theories able to account for the formation of hereditary material and a primitive genetic system. This is now the way origins of life are expressed. The question involves quite diverse disciplines, ranging from astrophysics and geology to physics and chemistry, from molecular biology to the theory of evolution. This borderline issue provides an opportune reminder that divisions separating disciplines are primarily the result of conventions and that fundamental unity does prevail at the heart of the subjects studied in science.

## CONCLUSION

The subjects addressed in this chapter, despite inevitable omissions, have covered some of the significant directions taken by science in the twentieth century. We have noted the gradual changes or complete breaks with the past, as well as links and lines of continuity between the different domains of science and between past and present knowledge. In conclusion, we can emphasize some general lessons that may reveal the general direction of future scientific advances and the promises they hold for us.

The *unity of matter* is a principle at the very foundations of all contemporary science and is illustrated in a particularly striking way in the corpus of modern scientific knowledge with its interconnections and mutual dependencies. This knowledge is organized into disciplines according to choices, attitudes and thoughts, and human decisions made in response to intellectual or practical requirements. They allow problems to be arranged in series, defining affinities among different subjects, and making it easy for us to approach the material world according to different levels of formal organization. The very concepts of *levels* and *organization* are part of the general frameworks or categories of thought on which knowledge and understanding are built.

Any definition and demarcation of disciplinary borders are eminently mobile: disciplines come together or diversify and new disciplinary fields are established; this appears as a general law applying to the organization of sciences. But while the 'total' category may no longer strike fear into the

hearts of today's scientists, methodological caution is still required (scientific *noblesse oblige*), and any moves they have accepted in coming together are invariably imposed by the logic applying to their work or to the subjects of their study.

Another lesson science has taught us through its very existence and its constantly changing nature is that science cannot be reduced to its achievements at any given point of time in history. It is first and foremost thought, but it is also *practice* and *work*, both intellectual and tangible, plus the potential for practical application. The problems raised by science range from internal questions related to the content of knowledge to issues of social responsibility, ethics and political implications. To be properly addressed, these general questions must be considered in the same spirit of discernment and critical reason required in science, but without being reduced to the level of science subjects, for they are issues of a different kind, linked to systems of values which are not to be found in nature. These vary depending on the science in question and, for some, like mathematics and the so-called 'exact' sciences reviewed here, reference can be made to an 'epistemological fence' which, starting from a threshold of 'guaranteed' knowledge, can be used as a conceptual approach to content that appear unaffected by other circumstances.

Science as thought (considered on a regional basis for each discipline, as well as on a more general basis) is part of a movement developed not only by the problems posed but also by the questioning of the content and meaning of the knowledge acquired. By focusing on description and explanation, science has invented new forms of understanding; it has revealed positive elements, describing phenomena and explaining the reason for their existence. With its own impetus, science strives to understand the relationships between these phenomena and to relate them to another deeper structural link derived from the subjects, by setting them into an intelligible pattern. These elements often have substantial implications for the general level of ideas, such as our concepts of space and time, or the principles underlying the laws of physical or biological phenomena.

But science also implies a representation of the world, going beyond mere reporting on relations and phenomena. This means creating new ways of thinking and conceptual innovations: science is then seen as work involving thinking and the sum total of acts of creative intellectual effort. While science is constructed (in the sense of constructing symbolic representations), it is also a critical thought process, raising problems of interpretation that are sometimes directly philosophical in nature. Proofs can be found, for example, for the curvature of space and the general theory of relativity, or concerning the question of 'physical reality', a subject of great debate in quantum mechanics. There are even proofs for certain aspects of cosmology and life sciences, such as the relationship between minerals and living organisms, evolution and the question of origins, or indeed, extending to a more general context, concerning the question of the nature of theoretical thought and its relationship to observation and experimentation.

Experimentation has been shown to be increasingly based on prior theoretical developments. The role of mathematics in physics is not for simple applications; mathematics is seen as a constituent of physical thought, being particularly well suited to displaying the structural aspect of the real physical

world, because of the qualitative approach and focus on relations, which is not solely concerned with quantity in the narrow sense of magnitude. The growing importance of topology in theoretical physics, along with metrics, may be significant here.

Deeper study of the nature of scientific work as an intellectual activity will inevitably reveal the close relationship with the philosophical attitude, alongside the huge technological resources needed for this work today. Looking beyond the formal changes over the past century in activities related to scientific knowledge, this dimension of science is probably the aspect most likely to ensure its ongoing sustainability and relevance, through its inability to settle for a closed representation and its irrepressible urge to doubt, criticize and start all over again.

## NOTES

1.    Dynamics: the effect of a particular type of force (e.g. electromagnetic dynamics or gravitational dynamics).

2.    Independently of the motion of its source. The speed of light in a vacuum is usually denoted by the symbol $c$, used hereunder.

3.    Vectorial addition, using the three space coordinates.

4.    For two collinear speeds, $u$ and $v$, their composition is
$$V = \frac{u+v}{1+\frac{uv}{c^2}}.$$
If one is the speed of light $u = c$ and $V = 0$).

5.    Low compared to the speed of light.

6.    An unstable particle known as a *muon* decays, having a life lasting 1 microsecond ($10^{-6}$ s), and has to cover a few kilometres ($10^{-6}$ m) before reaching Earth.

7.    $x_4 = ict$, with $i = \sqrt{-1}$.

8.    In this four-dimensional universe, Lorentz's transformations are rotations of the four coordinates, leaving 'distances' as invariants. The *metric* for this hyperspace (or Minkowski's universe) then featured an invariant element for 'distance', $ds^2 = dx_1^2 + dx_2^2 + dx_3^2 - c^2dt^2$, with the *signature* $(+,+,+,-)$ being the signature of a *quasi-Euclidean* space. In space-time, any action propagated at the speed of light covers spatial distance $x$ in time interval $t$ so that $x = \pm ct$. This equation defines the 'light cone'. The space-time region inside the light cone (known as 'timelike') is the area of physical actions between two of its points; the area outside (known as 'spacelike') is non-physical, as no pair of its 'four-points' can have a causal relationship.

9.    The quasi-Euclidean space-time metric of special relativity (see above) was then replaced by the most general form of metric, $ds^2 = \Sigma g_{\mu\nu}dx_\mu dx_\nu$. Here $x_\mu$ and $x_\nu$ are the generalized coordinates of space-time, and the functions $g_{\mu\nu}$ (such magnitudes with a number of indices are tensors) are the metric at each point.

10.    Einstein's equation links the metric tensor to the energy-momentum tensor of matter.

11.    An extra 43' of arc per century.

12.    Energy exchanged ($\Delta E$) is proportional to the frequency ($v$): $\Delta E = nhv$, $n$ being a whole number, and $h$ a constant of very small numerical value ($h = 6.55 \times 10^{-27}$ erg. sec), is the 'quantum of action' or 'Planck's constant'.

13.    Radiation energy is proportional to its frequency: $E = hv$. This relationship was verified with observations of the photoelectric effect.

14.    These negatively charged particles had been detected by Joseph J. Thomson in 1896.

15.    The relationship between momentum or the quantity of motion and the wavelength is:
$$p = \frac{h}{\lambda}.$$
Arthur Compton proved this in experiments in 1923, studying the collision of a photon with an atomic electron ('the Compton effect'). The radiation particles were named 'photons'.

16.    This means that every particle has a characteristic frequency related to its energy
$$(v = \frac{h}{E})$$
and a wavelength related to the quantity of motion
$$(\lambda = \frac{h}{p}),$$
in accordance with relationships previously established for radiation.

17.    Their intrinsic angular momentum or 'spin' is integral or zero (as a unit of the quantum of action $h$ or rather
$$\hbar = \frac{h}{2\pi}),$$
the spin of light (the photon) being 1: this feature has since been used to define one of the classes of quantum particles, the 'bosons'.

18.    In conventional statistical mechanics, particles, even when identical, are discernable.

19.    Fermions are half-integer 'spin' particles (units of the quantum of action): e.g. electrons have spin
$$\frac{1}{2}\hbar,$$
with two possible directions in a magnetic field.

20.    Two numbers, $x$ and $y$, commute: $xy - yx = 0$. Two matrices, $A$ and $B$, do not commute: $AB - BA = 0$. $\psi$. A matrix, or any appropriate linear operator, operating on the state function, produces an 'eigenvalue equation', such as $A\psi = a\psi$, $A$ being the operator (e.g. the Hamiltonian $H$ being energy), and $a$ the eigenvalue (a real or complex number).

21.    This probability is calculated as the square of the module (or absolute value) of the state function ($|\psi|^2$).

22.    The same state can be determined independently using another set of this type with quantities that do not commute with the first ones (incompatible or complementary systems). It was also shown that these operators could be constructed using equivalent classical numerical quantities as generators of infinitesimal transformations.

23.    $h$ being finite (non nil).

24.    EPR being the initials of the authors of an article published in 1935 in the *Physical Review*: Einstein and his colleagues, Boris Podolski and Nathan Rosen.

25.    Over the period 1964–1981.

26.    All that is needed, for example, is a highly rarefied beam with well-defined temporal distribution: it is known that, in a given time interval, one single particle goes through an interferometer.

27.    The exact value today for Avogadro's number is $N = 6,022 \times 10^{23}$.

28.    The corresponding quantum numbers being denoted, respectively, by $n$, $l$, $m$ and $s$; their possible values are determined by specific quantum rules. The spin of the electron can be aligned in one of two directions.

29.    *X*-rays have very short wavelengths of the magnitude of atomic distances and produce interferences in crystalline networks.

30.    With Hans Bethe, Eugen Wigner, John Slater, Nevill Mott and Harry Jones.

31.    Transistors are used in integrated circuits; with continuing miniaturization, they have now shrunk to a few tenths of a micrometer (chips).

32.    The absolute temperature scale has zero at $t = -273.16$ degrees Celsius, i.e. the temperature of 0 °C corresponds to $T = 273.16$ K.

33.    Superconductivity was discovered in the early twentieth century by Kamerlingh Onnes, working with mercury, and has since been explained by quantum theory. It is of considerable practical use: when used in electromagnetic circuits, it can produce intense magnetic fields without any loss of current, and is now used in large particle accelerators. Critical temperatures currently used are relatively low. But the possibility of finding materials which could be superconductors at temperatures closer to ordinary temperatures would open the path for an ever more prodigious range of applications, for example, magnetic levitation trains moving without any friction.

34.    In his theoretical work on monoatomic gas atoms ('boson gases'), based originally on an idea proposed by Bose.

35.    To achieve extreme cold, lasers are used, their light trapping the atoms in a magnetic field so that they cannot retrieve their kinetic energy.

36.    The dimensions of the nucleus are of the magnitude of $10^{-13}$ cm (1 fermi), while the distances at the atomic level are of the magnitude of $10^{-8}$ cm.

37.    The structure of the nucleus was then explained in terms of atomic masses (A) and atomic numbers (Z): a nucleus contains $Z$ protons and A-Z neutrons, and its mass is equal to the sum of the masses of the constituents minus their binding energy

$$(m_N = Z.m_p + (A - Z).m_n - \frac{\Delta E}{c^2}).$$

It was then possible to simply draw up the balance of energies expended or released in nuclear reactions.

38.    Isotopes are atoms with the same chemical properties and atomic number, but a different mass number: their nucleus has the same number of protons and a different number of neutrons. For one given stable element, there can be radioactive isotopes, which are unstable (because of the excess of neutrons): hydrogen, deuterium (both being stable) and tritium (radioactive) are isotopes. Carbon-14 (6 protons and 8 neutrons) is a radioactive isotope of stable carbon-12 (6 $p$ and 6 $n$).

39.    In these reactions where the total mass of the products is smaller than the initial mass, the difference in mass is turned into released energy.

40.    Thermonuclear fusion would still raise problems, as is the case with fission in today's nuclear power stations, for safety and the disposal of highly radioactive waste.

41.    In atomic and subatomic physics, energies are expressed in multiples of electron-volts (eV): keV (kilo eV, i.e. 1 thousand keV), MeV (1 million eV), GeV (G for giga, billion, $10^9$ eV), TeV (1 thousand GeV, i.e. $10^{12}$ eV).

42.    Binding energies at the atomic level range in magnitude from the electron-volt (eV) to the keV.

43.    For each particle there is potentially a corresponding anti-particle of the same mass and opposite in charge. The excitation of nuclear matter, by using sufficient energy, can produce a particle-antiparticle pair. The antiproton (with mass close to 1 GeV) was produced and identified this way in 1955 by Owen Chamberlain, on the Bevatron at Berkeley (6 GeV energy).

44.    From a few MeV to a few hundred MeV.

45.    One GeV and above (TeV by the late twentieth century).

46.    Gravitational force plays no role in atomic and subatomic physics because of the tiny scale of the gravitational constant. It does, however, come into play in a highly specific area, with very high energies in the first instants of cosmology, to be discussed below.

47.    $\beta^-$ radioactivity is expressed as an elementary process, in a nucleus: $n \rightarrow p + e^- + \bar{v}_e$. (A neutron decays into a proton, an electron and an antineutrino). The basic idea is that the transformation of a neutron into a proton goes with the transformation of a neutrino into an electron (according to Dirac's theory and quantum field theory, a neutrino destroyed is the same as an antineutrino created).

48.    The $p$ meson, which is present in a 'virtual state' in the nucleus, can be created in nuclear interactions by introducing mass, i.e. energy, according to the mass-energy relation $E = mc^2$. The concept of a 'virtual particle' comes from the *quantum field theory* which states that a physical vacuum is comprised of virtual particle-antiparticle pairs, having two physical consequences: vacuum polarization, as proven by the Lamb effect, and endothermic production of particles, confirmed by the possibility of producing particles providing sufficient energy.

49.    These resonances have an extremely short lifetime: approx. $10^{-22}$ s. Electromagnetic decay means a lifetime from $10^{-16}$ s to $10^{-18}$ s, while for a weak force it is $10^{-13}$ s and above.

50.    Formulated by Tsung Dao Lee and Chen Nin Yang and confirmed in experiments conducted by Chien Shiung Wu.

51.    Baryons have spin $\frac{1}{2}$ and $\frac{3}{2}$, mesons have spin 0, 1, 2 (in $\hbar$ units).

52.    *SU(3) symmetry* was postulated in 1962 by Murray Gell-Mann and Abraham Pais, and the idea of three *quarks* is the work of Murray Gell-Mann and George Zweig.

53.    The flavours of the three quarks are isospin 'up', 'down' and 'strange', giving the symbols *u*, *d* and *s*. Quarks have spin $\frac{1}{2}$ and fractional electric and baryonic charges ($\frac{1}{3}, \frac{2}{3}$). In this representation, mesons are quark-antiquark combinations, *baryons* are three-quark combinations (*uud* for the proton, *udd* for the neutron, etc.).

54.    Each flavour, corresponding to a distinct quark, determines a family of particles with a characteristic flavour: in addition to nucleons and *p* mesons and their excited states (distributed as electrically charged multiplets reduced to the *isospin* and comprised solely of *u* and *d* quarks), are the *strange* hadrons (with at least one *s* quark), discovered and studied in the 1950s and 1960s, the *charmed* hadrons (with one *c* quark) of the 1970s, then the *B* and *T* hadrons (incorporating respectively *b* and *t* quarks), identified in the 1980s and 1990s. These hadrons are ranked higher up the mass scale, and correspond to masses that could be assigned to elementary quarks: small for *u* and *d*, and increasingly higher for *s*, *c*, *b* and *t*.

55.    The six quarks have been given the following names: *u* (isospin up), *d* (isospin down), *s* (strange), *c* (charmed), *b* (beauty or bottom), *t* (truth or top).

56. Research by Aage Bohr, Ben Roy Mottelson and L. James Rainwater.

57. The development of series perturbations occurs following the increasing power of the 'coupling constant' measuring the intensity, which is small compared to unity: the series decreases quickly.

58. The 'Lamb effect' or 'Lamb shift' is the difference in certain fine structure levels of the hydrogen atom in relation to the values calculated (using Dirac's equation): the effect is actually caused by a 'cloud of virtual photons' or 'vacuum polarization' which quantum electrodynamics deals with by renormalization.

59. This term is purely metaphorical: the superposition of the three colours is neutral and colourless.

60. The idea of the mechanism, which was then generally adopted for studying symmetry, was actually the work of Brout, Englert and Higgs, who presented it in 1971.

61. A 'current' of particles expresses the transition from one state to another at the time of the interaction with the field: an electron interacting with an electromagnetic field emerges with no charge exchange (neutral current); but a neutrino turning into an electron in its coupling with the weak field, produces a charged current.

62. CERN: European Organization for Nuclear Research, near Geneva. The first reaction observed, a rare occurrence given the low probability, was: $\nu_\mu + e^- \rightarrow \nu_\mu + e^-$. Another and more frequent reaction is: $\nu_\mu + p \rightarrow \nu_\mu + p$ (the corresponding charged-current reaction is $\nu_\mu + n \rightarrow e^- + p$).

63. $q$ denoting quarks $u$, $d$, $s$, $c$, $b$ and $t$.

64. Two colour quarks $q_i$ et $q_j$ exchange a gluon $g_{ij}$ ($i$, $j = 1$, 2, 3). Studies of nuclear matter and the properties of parton-quarks had previously shown particles other than quarks present inside hadrons, suggesting that they may 'stick' the quarks together, hence their name, 'gluons'.

65. Among the most interesting phenomena revealed by quantum chromodynamics (which now uses them to test predictions) are 'jets' of quarks and gluons, the effect of the kinetic drift of particles emitted in collisions by interacting elementary particles: quark-antiquark fusion. These processes and others of a similar kind show that *valence quarks* are present and indicate the underlying presence of the ocean of virtual quark-antiquark pairs and also of gluons.

66. If the leptonic numbers are linked to the 'flavours' of quarks, each doublet of leptons matches a doublet of quarks ($e$, $\nu_e$ with $u$, $d$; $\mu$, $\nu_\mu$ with $s$, $c$; $\tau$, $\nu_\tau$ with $b$, $t$). This structure of elementary fermions divided into three families with universal coupling with interacting fields is probably due to an underlying and as yet unknown fundamental property. The number of these families is limited to three because of certain constraints: all quarks and leptons are now known.

67. Initially 'massive compact objects'.

68. These astronomical beacons emit radiation at radio frequencies with a periodicity of a few tenths of a millisecond, produced by the extremely fast rotation of the star around its axis: when the star collapses in on itself, the initial kinetic moment is retained, the effect being, as when skaters spin, a considerable increase in the speed of rotation. One of the best-known pulsars is the Crab Nebula, a remnant of the supernova seen in 1054 and recorded at the time by Chinese astronomers.

69. At the end of its life, a star produces a *supernova* if its mass is approximately ten times the mass of the Sun. One supernova is produced in each galaxy about once a century.

Supernovae also emit gravitational waves which, in theory, should be detectable and will no doubt be observed in the first years of the 21st century (see above, on general relativity). Once the iron core goes beyond a certain limit ('Chandrasekhar limit'), it collapses in on itself, and the outer matter is violently ejected.

70. Because of the weak interaction capacity of neutrinos, these are huge and positioned under thick layers of matter (in mountain tunnels, at the bottom of mine shafts, or even in submarines), for maximum filtering of background noise.

71. Hubble's relation is $z = \frac{\Delta\lambda}{\lambda} = H_0 L$, $\lambda$ being the wavelength, $\Delta\lambda$ the wave shift, and $H_0$ Hubble's constant (re-evaluated in the 1980s and set at 100 kms per s and per megaparsec (1 pc, parsec = 3.26 light-years). The spectral shift is interpreted as a Doppler-Fizeau effect caused by a movement away at speed $v$, $z = \frac{v}{c}$.

72. The proportion of deuterium is 25 per cent.

73. The cosmological principle involves a special form of metric known as the Robertson-Walker metric.

74. These models are mathematical and the term 'singularity' is used with that meaning.

75. Between 50 and 100 kms per s per megaparsec.

76. The most commonly accepted value is in the vicinity of 15 billion years. In 1998, observers using high-resolution telescopes detected two very primitive galaxies on the 'bounds' of the Universe, at 12 billion years or more.

77. That is, $10^9$ times the number of baryons (neutrons and protons) which comprise observable matter.

78. These particles should differ from known particles which had interactions that determined the formation of the Universe as described in the 'cosmology of the first instants'.

79. The grand unification field from $10^{-43}$ s to $10^{-35}$ s, the dissociated chromodynamic and electroweak fields from $10^{-35}$ s to $10^{-32}$ s with a predominance of quarks and leptons, then the three separate fields (strong, electromagnetic and weak) from $10^{-32}$ to $10^{-12}$ s with a 'soup' of particles and antiparticles; next, from $10^{-12}$ to $10^{-6}$ s (one microsecond), matter is a broth of particles and radiation; on cooling, after approximately three minutes, matter is converted into hydrogen, deuterium and helium nuclei (this is the radiation era when matter and radiation uncouple, with the cosmogenesis of light elements); around 100,000 years, the nuclei attract electrons, forming atoms, emitting isotropic electromagnetic radiation.

80. Starting in the late 17th century with the mechanics in Isaac Newton's *Principia*, until the late 19th century with James Clerk Maxwell's electromagnetic theory, and covering the 18th century with work on fluid mechanics by Jean d'Alembert and Leonhard Euler, and Joseph-Louis Lagrange's *Analytical Mechanics*.

81. The bomb was developed in the Los Alamos Laboratory, in the United States, between 1942 and 1945. At the same time scientists learned how to control the production of nuclear energy, with the first atomic pile used to enrich uranium with fissile matter and transform it into plutonium: nuclear piles and reactors were subsequently designed to generate electricity. Nuclear physics and elementary particle physics as we know them today are the direct result of this history so closely bound up with the political situation. The paradox is that today, with the establishment and operation of CERN (the European Organization for Nuclear Research) near Geneva, on the

border between France and Switzerland, they provide a model for international scientific cooperation and partnership, conducted in a spirit of peace, but also with direct involvement of the different states. However, as research into subatomic physics has gone deeper, knowledge has moved away from practical applications, which are now mainly seen as the domain of industrial technology.

82.  Ranging from electrostatic accelerators with protons and light nuclei to heavy ion accelerators first developed in the late 1960s.

83.  Ranging from cyclotrons and linear electron accelerators to proton synchrotrons and proton-antiproton and electron-positron collider rings.

84.  One of the great advances in this field in recent times was the achievement of the technique known as stochastic cooling developed by Simon van der Meer, which made it possible to use controlled beams of antiprotons in the $p - \bar{p}$ collider ring at CERN, an essential tool in the early 1980s for producing and identifying intermediate bosons, as mentioned above.

85.  Visual detectors, photographic emulsions, Wilson chambers and bubble chambers, electronic detectors, Geiger counters and multi-wire proportional chambers developed by Georges Charpak: these were the forerunners of the large 'drift' wire chambers and three-dimensional designs; since the 1980s, these have replaced the other high-energy particle detectors. These chambers can be used together with particle identifiers and 'calorimeters' to measure energy for full reconstition (on-line, on computer) of the most complex reactions, thus combining the advantages of the precision visual detection previously used and the statistical accumulation of electronic detection data.

86.  This acuity, which the designers say gives visibility capable of distinguishing a pea at a distance of a thousand kilometres, is increased by sophisticated optical interferometry techniques first developed in 1976.

87.  Special infrared telescopes also exist.

88.  NGST: New Generation Space Telescope.

89.  Alfred Wegener, *Die Entstehung der Kontinente und Ozeane*, 1915 (and the expanded 1929 edition). Eduard Suess (author of *Das Antlitz der Erde*, 3 vols., 1883–1909), who described the crust and mantle of the Earth in terms of sial and sima, had previously suggested to Wegener that an original southern continent named *Gondwana* had existed, joining Africa to India. But as he had adopted the argument that the cooling of the crust would cause contraction, he interpreted the morphological complementarity of the coasts as continents collapsing. Reference must also be made to the important work by Émile Haug (*Traité de géologie*, Paris, 1907–11) on structural geology and geosynclines, which are marine sedimentation depressions that sank deeply over long periods and, according to Haug, had heaved, moving upwards and causing mountain ranges to form.

90.  These changes, according to one of the most widely supported hypotheses, were caused by the impact of a giant meteorite; the crater was identified in Mexico and analyses detected traces characteristic of iridium.

91.  Relative dating (establishing contemporaneity) and absolute dating using radioactive substances, including radiocarbon (the carbon-14 method devised in 1949) for organic matter, can be used for periods up to -40,000 years. For much earlier periods, other radioactive substances, found in eruptive or sedimentary rocks, are used.

92.  This synthesis may have occurred in other environments, e.g. meteorites in space, these being the fossils of the primitive matter in the solar system, with many organic molecules, or even other planets and their satellites, which can help determine the physicochemical conditions of the primitive Earth.

93.  See, e.g., Graham Cairns-Smith's theory of genetic take-over, i.e. that a clay (mineral), playing the role of a primitive enzyme, may have catalysed the polymerization of the molecules absorbed on the clay surfaces in the form of laminae, at the point where earth and water meet; the polymer chains thus formed could have then acquired a permanent capacity to reproduce autonomously.

## SCIENCE AS A SYSTEM OF IDEAS
## FIRST HALF OF THE TWENTIETH CENTURY

### *Ludmila A. Markova*

In the twentieth century, there emerged a veritable confraternity of scholars – sociologists, philosophers and historians – engaged in specific areas of research in the social sciences. This confraternity was based not only on a shared object of study, but also on a wide range of social factors. The latter include a common language (the overwhelming majority of works are written in English), a common territory (mainly Western Europe and North America), and the opportunity to meet and exchange ideas at conferences, seminars, by student and professor exchanges and the preparation of joint publications, etc. Thus, we can speak of the existence of an integrated community of researchers who, through their combined efforts, reflect the state of twentieth-century study. Naturally, this community does not exist in isolation. The discussion of any serious issue can prompt the members of this community to examine the history of their own or outside disciplines or to engage in ideological disputes.

Consequently, research also reflects the opinions of non-professionals. Natural scientists, writers, politicians, economists, etc., express their views on science. Their viewpoint is often of considerable interest, but we shall focus our attention on professional research.

As a rule, the arguments of researchers are conducted along one of two axes. Science may be understood as:

1) a system of ideas within society,
2) activities undertaken to acquire knowledge.

Up to the mid-twentieth century, primarily the first axis was developed, eclipsing activity undertaken to acquire knowledge.

When science is seen as a system of ideas, it is assumed that in their development, these scientific ideas are influenced to some degree by aspects that are external to the ideas themselves (production, politics, religion, etc.). When analysing the way in which science functions within society, the main role is accorded to the outcome of scientific research and its uses by society. Little importance is attached to examining how these ideas emerged as a result of the creative activity of the scientist. Yet, any analysis of the logical structure of scientific knowledge itself is conducted exclusively on the basis of its internal logic, independently of the social or cultural milieu. It was precisely this interpretation of scientific knowledge, which, in the mid-twentieth century, lay at the basis of the two opposing schools of thought in the historiography of science, namely internalism and externalism.

If science is studied as a social institution (universities, academies, research institutes and groups) existing within society, this presupposes a study of the characteristic features of this institution, which has its own hierarchy, personal ethical norms of conduct, individual stimuli and distinctive system of motivation and censure. The social institution of science can exert no more direct influence on the content of scientific ideas than can society in general. The main contribution to the elaboration of this view of science in the twentieth century was made by R. Merton, the founder of the sociology of science.

Until the mid-twentieth century, the philosophy of science was dominated by the positivist school, whose followers reduced the analysis of science mainly to an analysis of scientific language. According to the positivists, the essential concept is that of demarcation, that is, the rigorous separation of science from metaphysics and history. Moreover, they believe that science should be studied by scientists using strictly logical methods and that the most fruitful line of research is the analysis of modern scientific systems without reference to metaphysics. These ideas were given their clearest formulation in the works of R. Carnap, C. Hempel, E. Nagel, and other researchers, the majority of whom were members of the Vienna Circle of logical positivism, which emerged from a seminar organized by M. Schlick at the Department of the Philosophy of the Inductive Sciences at the University of Vienna. The circle ceased its activities following the annexation of Austria by Germany (*Anschluss*) in the late 1930s.

In the history of science, the concept of gradual advance in the development of scientific knowledge has held a central place. In such a cumulative process, each new achievement provides a fuller and more adequate picture of the natural world and more accurate knowledge. A new idea emerges from the preceding idea and becomes the basis for the next advance. The most striking proponent of this view of the history of science was the French historian of science P. Duhem at the beginning of the century.

## SCIENCE AND EXPERIMENTAL KNOWLEDGE – THE PRINCIPLE OF THE ECONOMY OF THOUGHT

When, in the early twentieth century, scholars discussed the relationship between science and society, they usually had in mind not the political, social or economic structure of society, but the experience acquired by men in the course of their everyday activities. How does such experience correlate with scientific knowledge? To what extent are their systems related? Which comes first? How do they relate to each other in the history of humankind and in the life of the individual? Answers to these and other similar questions had been sought in the nineteenth century by the founders of positivism (A. Comte, H. Spencer), and these issues were at the core of the work of E. Mach. All these scholars attempted to identify the shared characteristics of scientific thought and common sense and the link between science and practical experience.

Mach noted that, in the course of our everyday activity, we establish a link between natural processes and our own needs.[1] The satisfaction of needs leads to the emergence of instinctive, involuntary knowledge of the processes of nature that apparently always preceded scientific, deliberately acquired knowledge. Science developed out of manufacturing as a result of the need to pass on the results of the experience acquired in the process of manufacturing to others. This was how science emerged historically, but in the course of its subsequent development, logical, scientific knowledge has always been based on experimental knowledge.

Mach argues that the partly instinctive, partly conscious accumulation of experimental data preceded its scientific systematization. Usually, when we wish to introduce someone to natural phenomena or processes, we do not oblige the person to observe them directly, but we describe this natural process in some way so that the person does not have to undergo the experience. According to Mach, this economy of thought and understanding constitutes the essence of science.

Historically, science emerged as a consequence of the desire to pass on to future generations as economically as possible the knowledge accumulated in the course of practical activities such as to make clothing, weapons, shelter, etc. This economy was achieved by systematizing knowledge, and thus it was gradually given logical, scientific formulation. Scientific knowledge becomes logical and rational only after emerging from experience. The process of the emergence of knowledge is excluded from the rational, logical sphere.

Mach introduced the concept of conditionality and conventionality into scientific knowledge, an area on which Duhem was later to focus his attention. It is precisely these elements of conventionalism in Mach's theory that undermine his initial postulate on the identical nature of everyday and scientific knowledge. Everyday knowledge is something we acquire in our practical activity, which does not obey the logical laws of the development of scientific knowledge but has its own laws of development. The specific characteristics of the development of science do not in any way determine which natural phenomena will interest us in the course of our practical activity. The link between practice and science emerges fortuitously, arbitrarily and unpredictably. Although experience and practical knowledge are the source of scientific knowledge, the genesis of scientific knowledge from experience cannot be logically understood. There is a 'gap' separating practical activity from scientific activity.

## CONVENTIONALISM IN THE CONSTRUCTION OF PHYSICAL THEORY

This gap separating practical and scientific activity is carefully explained in the work of P. Duhem, who distinguishes science from common sense, from the experience acquired in the course of practical activity, from manufacture and production, from civil and political history,[2] thereby placing the emphasis on the logical aspect of scientific knowledge, that is, on one of the characteristics that distinguish it from everyday knowledge.

Duhem follows Mach in recognizing the principle of the economy of thought, and suggests that physical theory is constructed in accordance with this principle. Experimental law replaces an enormous number of concrete facts by abstraction, which ignores the specific or individual aspects in each of these facts in order to extract from them that which they have in common and which is of general significance. Theory is precisely the economic presentation of physical laws and their classification.

The principles or hypotheses, which we formulate in order to systematize facts concentrated in physical laws, are formulated arbitrarily and independently of experience. Mathematical operations are carried out on the basis of these principles independently of any link with experience. If, as a result, the physical theory corresponds to reality, it is quite fortuitous, quite involuntary. To believe that our theory corresponds to the natural order is an act of faith.

According to Duhem, physical theory is not an explanation but rather an image of the natural order. The physicist is unable to prove this, but he 'cannot free himself of the idea' that this is so. Thus an 'irrepressible conviction' of the truth of this view is aroused within him, and he 'is not aware' of this conviction even though he 'senses' that it is correct. The fact that we believe in the predictive power of physical theories is seen by Duhem as the most convincing evidence of our belief that theoretical classification is part of the natural order. According to Duhem, the result of a physical experiment is not an observation of facts, but an interpretation of those facts that are transferred into the ideal, abstract, symbolic world created by theories the physicist believes to be correct.

It is above all the symbolic nature of physical laws that distinguishes them from the laws of common sense, which may be true or false. The laws of physics, on the other hand, expressed in mathematical form, are always symbolic, and a symbol can be neither correct nor erroneous.

In the course of its construction, a physical theory may select any route, provided it does not lead to logical contradiction. For example, Duhem asserts that a theory may completely ignore facts acquired experimentally. However, when the construction of the theory is complete, the group of mathematical propositions derived from these deductions must be compared with the group of experimental facts. This comparison, which is conducted by measurement, reveals whether or not the experimental facts are adequately reflected in the mathematical symbols. If no such correspondence between the conclusions of the theory and

the experimental facts is found, then the theory must be rejected, even if its construction is perfectly logical, since it contradicts observation, and is physically false. Only the conclusions of a theory are seen as the reflection of reality.

The moment an old theory has to give way to a more promising, new theory is not determined by logic. This moment is determined by common sense, and therefore, according to Duhem, it is very important for the physicist to completely retain common sense. When speaking of the emergence of new ideas in the mind of the scientist, or about his decision to reject an old theory and adopt a new one, Duhem wishes to emphasize that any creative process steps outside the boundaries of the logical, deductive development of scientific concepts and is determined by non-logical factors. All logical operations are carried out conventionally on the sole basis of agreement among scientists.

## THE PRINCIPLE OF CONTINUITY

The positivist tradition of the nineteenth century, which viewed the development of science as a continuous, cumulative process, was carried over into the twentieth century and continued into the 1950s. The history of science reveals more clearly than any other human activity the process of the accumulation of knowledge, and this factor became the objective basis for formulating the cumulative model of scientific development. The basic postulates of this theory are as follows:

Each advance in science is made only on the basis of previous achievements; new knowledge is always more complete and an improvement on previous knowledge. As it is more accurate and a better reflection of reality, the entire course of development up to this point can be seen as a preparation for the present situation. In this sense the history of science is progressive.

Only those elements of past scientific knowledge that correspond to current scientific theories have any significance. Ideas and principles that have not become part of current scientific knowledge are erroneous and, historically speaking, represent misunderstanding and deviations from the highway of scientific development.

The ideas of cumulativism were given their most complete and developed elaboration by Mach and Duhem. Mach saw the extension of an existing method of understanding to include a new group of facts as the main element in the thinking of the natural scientist. He termed this element the principle of continuity, the essence of which was to identify uniformity in natural phenomena and to present new facts in such a way as to bring them under known laws. A scientific discovery consists in presenting an unknown, inexplicable phenomenon or real fact as similar to something already known and obeying the same rule or law as the known phenomena. According to Mach, a scientific discovery is not a break in continuity, a revolution, but, on the contrary, is possible only when the natural scientist operates according to the principle of continuity.

## SCIENCE, LIKE NATURE, DOES NOT MAKE ABRUPT LEAPS (P. DUHEM)

For Mach, the problem of scientific discovery as a deviation from the continuous advance of scientific knowledge does not exist. Duhem sees a problem, but also its solution. All his arguments lead him to believe in the continuous, progressive development of science. The basic postulate upon which Duhem bases his arguments on this issue is that, although there can be no doubt that the history of science reveals the phenomenon of major leaps, revolutions, nonetheless they must be brought within continuity and included within some rational, historico-scientific reconstruction, in order to be comprehensible. It was in developing this idea that Duhem arrived at the 'rehabilitation' of the Middle Ages. He was the first historian of science to show, convincingly, and on the basis of facts, that medieval science has been of tremendous importance in shaping the natural science of the modern age. In his works, the Middle Ages ceased to be a dark age, a period in which no rational scientific thought existed. Duhem scrupulously traced the delicate intellectual threads linking the thinkers of various generations and ages. From this point of view, his research into the legacy of Leonardo da Vinci is particularly interesting.[3] The subtitle of this work speaks for itself: 'Those whom he read, and those who read him.' That is, Duhem studies Leonardo's predecessors and those who then used his ideas in their research.

In Duhem's opinion, the history of science is distorted by two prejudices: it is usually thought that scientific progress occurs as a result of sudden and unexpected discoveries; it is assumed that such progress is the fruit of the labour of genius, who has no predecessors. In fact, however, the history of science adheres rigorously to the law of continuity. Great discoveries are almost always the fruit of slow and complex preparatory work conducted throughout the centuries. Even those who are traditionally considered to be creative scientists, such as Galileo, Descartes, Newton, did not formulate theses that were unrelated to the teaching of their predecessors. An oversimplified account of history obliges us to admire them and see them as colossi having no roots in the past and incomprehensible in their isolation. However, more detailed investigations enable us to trace the long line of development that culminates with these geniuses. According to Duhem, science, like nature, does not make abrupt leaps.

Duhem refers to the concept of continuity and to the cumulative nature of scientific development in all his historical works, including the monumental multi-volume work entitled *Le système du monde*,[4] in which he follows the genesis and development of cosmogonic concepts from ancient times to Copernicus. Duhem believes that there is no absolute principle in the genesis of a scientific thesis. However far back into the past we trace the chain of thought that preceded and prepared the way for this thesis, we always encounter ideas that resulted in their turn from earlier ones. If this tracking of successive ideas comes to an end, it is not because we have discovered the first link, but because the chain has disappeared into the depths of history.

Writing about physical theory as such, Duhem states that it is not the product of a moment of creativity but, on the contrary, it is always the result of a slow and progressively developing evolutionary process.

Duhem shifts the emphasis in the interpretation of the cumulative nature of the history of science to the development of scientific ideas by not only separating science from metaphysics more clearly than his positivist predecessors, but also by separating it from social and

political history, common sense and from experience acquired in the course of practical activity. As for the problem of the relationship between science and metaphysics, Duhem relies on the assertion common to all positivists, namely that natural science does not have to strive to explain reality, that is, to reveal that which is concealed behind the phenomenon as if behind a smoke screen. When the natural scientist nonetheless attempts to offer an explanation, that is, when he engages in metaphysical argumentation, he is in no way furthering scientific thought. Metaphysical arguments on the essence of phenomena are not only unnecessary for the physicist, but even impede him, and if they serve to provide some external stimulus in achieving any significant results in science, it is purely fortuitous.

According to Duhem, in order to arrive at a physical explanation, it is essential to determine the nature of those elements making up material reality and not directly accessible to the human senses. This raises two questions: is there in fact such a thing as material reality apart from sensorial phenomena? If so, what is the nature of that reality? However, answering these questions is the task of metaphysics, not physics. Physics uses the experimental method, which deals only with sensorial phenomena, and which cannot discover anything outside of them. Duhem warns that to attribute an explanatory function to physical theory is to subordinate physics to metaphysics and to deprive physics of its autonomy.

Thus, Duhem arrives at the cumulative nature and continuity of the development of physical ideas by including within the history of natural science only the descriptive part of the theory. All the revolutionary elements are attributed to the history of metaphysics.

## INTERNALIST AND EXTERNALIST INTERPRETATIONS OF SCIENCE

If science is understood as the totality of scientific ideas, then the researcher who undertakes the study of science is faced with the discipline's dual nature. On the one hand, scientific ideas exist independently of the individual and of the historical period from which they emerge. They depend above all on the specific nature of the object of study (the natural world); scientific ideas follow and support one another thereby forming an integrated system of knowledge. On the other hand, one cannot ignore the fact that scientific ideas emerge in the mind of a given scientist and that their appearance is assisted or impeded by various events and factors which, at first glance, have no relationship whatsoever to the rigorously logical structure of scientific knowledge. Such factors may be related to social, cultural or political circumstances or they may relate directly to the life of the scientist.

Science can be divided into two categories: *objective* science, or the sum of ideas existing independently of the subject, and *personalized* science, which is linked to the scientist's activity of generating knowledge and its social, political and religious aspects.

This duality gave rise to the emergence of two methodological schools in the historiography of science in the mid-twentieth century:
  – internalism, whose proponents view the history of science as the history of scientific ideas whose development is governed by its own internal laws;

  – externalism, whose adherents view the history of scientific ideas as being determined by social context.

The mid-twentieth century was marked by stormy debates between these two schools, whose representatives met at international congresses and conferences. There were many publications in the form of journal articles, books and documents resulting from conferences and symposia.[5] Among the more active participants in these debates were A. Koyré, R. Hall and J. Agassi, who consistently supported internalism, and R. Merton, A. Crombie, G. Guerlac, E. Zilsel, J. Needham and S. Lilley, who defended the sociological interpretation of the history of science.

An analysis of these historians' comments on each other's views reveals that the supporters of the sociological interpretation of the history of science criticize their opponents for paying too little attention to the social aspects of the development of science.

Crombie claims that historians of the internalist school fail to study the motives and aims of science, the spread and application of scientific discoveries, etc. Guerlac accuses internalist historians of ignoring the link between the genesis and history of science and the rise of technology, although it is obvious that science is deeply indebted to practical activities and to the arts. Similarly, Needham is of the opinion that scientists are constantly coming up against practical problems and cannot avoid them.

For their part, the internalist historians see their opponents' weakness as lying in their failure to take into account the main content of science, that is, the development of scientific ideas, which takes place autonomously, according to Koyré.

Hall believes that the history of science is above all an intellectual history, and that it can in no way be explained by external factors. He particularly stresses the enormous difference between the two approaches to the study of the history of science and has spoken publicly more than once about the fundamental difference between them.

Yet, in a number of cases, if the debate continues (for example, the dispute between Merton and Hall on the origins of European science), it finally appears that there was nothing to argue about because this is not a case of two opposing and incompatible approaches, but of different subjects of research. It therefore should be possible for each side to carry on with its work without hindering the other.

## METHODOLOGICAL OPPONENTS SHARE THE SAME CONCEPT OF SOCIAL CONTEXT

Both internalists and externalists agree that the social context of science derives exclusively from the influence of external social factors (hence the name 'externalism') – economic, military, political, legal, etc. – on the development of scientific knowledge, which possesses its own 'internal' laws that determine the logical link between scientific concepts and between all the elements of the theoretical content of science. All researchers recognize that scientific knowledge, with its own internal logic, is relatively free from the influence of external social factors.

Social factors may accelerate or impede the development of scientific knowledge, change its direction, but they cannot exert direct influence on the internal logic and content of scientific ideas. This fact is generally recognized by both

schools: internalists, who reconstruct the logic of the development of scientific ideas, do not feel the need to study external social factors, while externalists, who conduct sociological research into the history of science, do not claim to analyse scientific knowledge per se. There exists, as it were, a 'division of labour' between science historians.

The concept of social context to be found in the works of both internalists and externalists as something accepted axiomatically and beyond all doubt presupposes the division of labour within society and an exchange of the results of the various types of activity. The scholar, the industrialist, the military commander, the administrator pursue their tasks, and specific social relationships exist between them and representatives of other spheres of activity. When the process of discovery or invention is complete, the scientist's task is to present his or her results in a practical form to be 'used' (in the broadest sense of the term) by other scientists and those involved in other types of activity (economics, politics, culture, etc.). This gives rise to a corresponding set of relationships. A scientist who has made a breakthrough in science is of interest and value to society as someone possessing certain information that can be transferred to others. The history of the discovery, that is, the scientist as an individual, is of no importance to society as regards the successful use of scientific results.

Similar demands are made on the person who receives the information. Qualities that might help decode the information and understand its genesis are not required. Such qualities might even hinder the successful exploitation of the newly obtained information. Indeed, if the scientist began to view each mathematical formula needed for his work in terms of the 'history' of this formula – its genesis or discovery – he would scarcely make any progress. The assimilation of the history of science in the form of the acquisition of ready-made information requiring no further verification is an essential element of all scientific work. This method of assimilating history is even more necessary and inevitable in material production, in everyday life, particularly when the results of scientific activity are being used.

In order to be able to make use of a television or refrigerator effectively, it is quite sufficient to be able to turn and press the appropriate buttons and switches. This equipment is made to be used by those who know nothing of its construction.

In order to make use of scientific discoveries in the manner described above, simple customary practices are quite sufficient, and personal qualities are irrelevant and can even be an impediment. Hence the wide possibilities of interchange: the same functions within society can ideally be performed by anyone, that is, the activity is constant and invariable. In the same way, in the history of science, scientific knowledge is impartial as regards the personality of the scientist, and also the social and cultural characteristics of the period in which this knowledge was brought to light. The most detailed and careful study of the social conditions accompanying the appearance of new scientific ideas will not lead the historian to the content and logic of scientific knowledge (externalism), while a scrupulous analysis of the internal logic of a scientific theory does not require any reference to the social context of scientific activity (internalism).

Activity to produce scientific knowledge in all its forms is separated from the result obtained. This interpretation of the social context of science would appear to be flawless. However, it has its limits.

## THE CONCEPT OF SOCIAL CONTEXT AND NATURAL SCIENTIFIC THOUGHT

The type of social context that predominates in the modern age (above all, with regard to material production), and is based on the division of labour and the exchange of the results of activity, also corresponds to certain features of theorization in classical natural science.

The dominant tendency in man's cognitive attitude towards nature is to view it as something alien and opposed to him. However, when cognition of the external world, existing independently of man as an object of study, assimilation and use, is understood only as a process directed outwardly, leading potentially into infinity and not restricted to man, then there is no longer any need to refer to social factors in order to explain the nature of scientific knowledge as such. The scalpel of natural science uncovers ever-deeper layers of nature, and it is possible to forget the fact that the scalpel itself (the technical equipment of science, its material resources, experimental apparatus, and the intellectual, logical capacities of the scientist) changes and improves. The internal content and structure of knowledge depends on the nature of the revealed layers, and not on the characteristics of the scalpel. The history of human relations – indeed the history of human society – is the prerequisite for the emergence of scientific knowledge. Yet, however intensely one may study social history, one will never draw any closer to understanding the structure and content of the knowledge in question, which reflects and reproduces a natural world existing objectively and independently of man.

Scientific knowledge cannot be conceived distinct from human society. It is created by men but, ideally, the closer it comes to absolute truth, the more it is cleansed and freed from all that is 'human', that is, subjective, transient, illogical or fortuitous. However, if the subject is deprived of all its distinguishing features, the subject as the 'cognizer' becomes invariable, always one and the same. The phenomenological fact that humankind is developing, and that the personal characteristics of the scientist change accordingly, should be taken into account only for the purpose of understanding what needs to be excluded from the process of cognition, the objective being to acquire truly objective scientific knowledge of the real world.

If we follow this line of thought, the social relations involved in the process of obtaining knowledge about the natural world lose their historical character. Communication among scientists does not depend on whether they belong to different periods or are contemporaries but occurs quasi-simultaneously. As it develops, science gradually frees itself from errors and mistakes linked to the subjective aspect of cognition, and carefully preserves the pieces of objective truth about the world that are not influenced by fortuitous historical events and factors.

The opposite point of view, which involves recognizing that the content of scientific knowledge is influenced by changing social factors is described as 'relativist' and justifies the arbitrary and chaotic nature of the history of scientific ideas. Ideally, the subject should be freed from all historical associations to avoid 'sullying' the logical flawlessness of objective scientific thought. In this sense, social aspects are entirely excluded from the development of scientific ideas.

This interpretation of the social context, applied axiomatically, represents the basis of both the internalist and externalist methodological trends in scientific historiography.

Scientific ideas develop according to their own laws. While social factors may accelerate or hinder their development as an external cause, they can in no way invade the content or the inner, logical structure of knowledge.

## THE MODUS OPERANDI OF SOCIAL DEMAND

Social demand is a powerful stimulus regulating scientific progress. Certain requirements emerge within society as a result of political, military and economic development, and these requirements can be satisfied by science. For example, the development of agriculture gives rise to a need for new types of fertilizers, and society places such an order with science. Society is quite unconcerned about the scientific methods used to satisfy this order. What matters is to obtain results of scientific research that can be exploited. The scientist, for his part, does not need to know how this order came to be formulated within society in order to carry out his work successfully. The priority is placed on social development.

In the case described above, social influences on science function as external forces to stimulate action, but they are not responsible for the laws governing this action: a crop failure obliging researchers to intensify their work in a particular area of chemistry does not determine the methods of scientific thinking. The internal nature of the external force is not important in terms of understanding the laws that govern the action generated. The result of scientific activity transmitted to society for exploitation also acts as a force that generates certain activity (for example, the use of fertilizers accelerates plant growth). However, the laws of this activity are not determined by the applied force (a plant may grow more quickly or more slowly, but it grows according to its own biological laws, which cannot be determined by new chemical fertilizers).

A correspondence can be demonstrated between social relationships and the logic of reasoning in contemporary natural science. In Newtonian mechanics, the nature of the forces causing motion is not known. These forces are characterized exclusively by the motion they cause. Kinetic laws of motion do not depend on the nature of the force that causes the motion. The motion of material bodies in this theory is reduced to the motion of material points. This means that kinetic laws of motion do not take into account the internal structure, the content of the moving bodies, nor those changes that take place in them as a result of the movement.

Scientific knowledge as a result concentrated within a mathematical point (the content of knowledge has a significance revealed only in its action on something else; as an operating force, it can be equated with a point) exerts a certain influence on processes within society, and similarly, the results of social development exert their influence on scientific progress.

## THE ESSENCE OF THE SEVENTEENTH-CENTURY SCIENTIFIC REVOLUTION

In the historiography of science in the mid-twentieth century, French science historian Alexandre Koyré appears in two guises. On the one hand, he was an energetic supporter of the internalists and believed in the autonomous nature of the development of scientific ideas. On the other hand, he was the main opponent of Duhem, disagreeing with the latter's concept of the continuous development of scientific knowledge. Duhem and Koyré differed fundamentally in their interpretation of the scientific revolution of the seventeenth century, and it was precisely this analysis of the seventeenth-century scientific revolution that honed their views of the development of the natural sciences. The mid-twentieth-century reassessment of the interpretation of the history of science based on cumulativism, continuity and progress was linked to a general crisis in positivist philosophy, which was then reflected in the historiography of science via the introduction of the concepts of discontinuous development, particularity, uniqueness, and revolutionary change. The first major shift in this direction came in the works of Koyré, who views the sixteenth and seventeenth centuries as an era of fundamental, revolutionary changes in the history of scientific thought. While studying this period, Koyré came to the conclusion that the European mind had achieved a profound intellectual revolution that modified the very foundations and structure of our thinking. This revolution occurred not only in science but also in philosophy.

Koyré opposed any attempt to minimize or even simply deny the originality and revolutionary nature of Galileo's thinking. Koyré showed that the seeming continuity in the development of medieval and modern physics – the continuity so persistently emphasized by Duhem – is merely an illusion. Koyré did not deny the existence of a tradition encompassing the works of medieval scholars and those of Giordano Bruno, Galileo, and Descartes, yet held that the conclusion reached by Duhem is mistaken. A well-prepared revolution is nonetheless a revolution.

Koyré describes the essence of this scientific revolution as follows: first and foremost, it led to the collapse of the cosmos, and also to the geometrization of space. Prior to this revolution, the cosmos had been seen as a perfect and ordered world in which the spatial structure embodied a hierarchy of values and degrees of perfection and the heavenly spheres 'rose above' a heavy and impenetrable earth. This was replaced with an infinite universe that did not incorporate any natural hierarchy and was held together only by identical laws. The second feature of this revolution, the geometrization of space, was closely bound up with the first. The Aristotelian concept of space as the differentiated totality of locations within space gave way to a Euclidean geometrical concept of space as a homogeneous and infinite extension.

All of this caused scientific thought to reject all considerations based on concepts of value, perfection, harmony, emotion and aims, and eventually led to the complete devaluation of God, to a complete rupture between the world of values and the world of facts. The most fundamental work by Koyré, where he developed and argued his concept of scientific revolution, is his *Etudes galiléennes* (1939).[6] For a long time thereafter, Koyré's research became the banner of the opponents of positivism in the history and philosophy of science.

## SCIENCE AS THE ACTIVITY OF ACQUIRING KNOWLEDGE
### SECOND HALF OF THE TWENTIETH CENTURY

*Ludmila A. Markova*

### INTRODUCTION

In the first half of the twentieth century, the majority of researchers sought to isolate the content of scientific knowledge from social influence. Over recent decades, emphasis has been placed on the fact that knowledge does not exist independently but is shaped and determined by society. One reason for this shift is the attention focused on the process of acquiring knowledge. Knowledge is not a ready-made result independent of the process that produced it; rather, the means of acquiring knowledge can be found within knowledge itself.

During distinct periods in history, different methodologies have been used in the natural sciences. Similarly, methods of cognition vary according to the particularities of the social structure and culture. However, different methods presuppose diverse results, and the content of scientific knowledge changes from one epoch to another, since nothing is stable or constant. This content loses its objective character, and the question of truth loses its significance. If such a viewpoint is taken to its logical conclusion, it would appear that the structure and content of scientific knowledge merges with the act of acquiring it and that this activity is determined by society. One can therefore conclude that scientific knowledge is shaped by society, and its content in no way depends on the natural world as cognized via science. Moreover, it is supposed that the scheme of scientific theorizing is transferred directly from society to science. No allowance is made for the fact that the internal social content of science itself integrates and idealizes the ways of thinking of a given age, and only then do the norms of thought pass from science and philosophy and spread into society.

It is of course true that various methodologies, different types of thinking in various epochs, give rise to different forms of knowledge, but distinctive types of thinking realize or give substance to various aspects, leading to many possibilities within reality – that same natural reality that always remains the object of scientific study. The logical structure of a scientific theory is examined in light of its ability to compete with opposing points of views and its development into a new theory defended by other representatives of the scientific community.

In the mid-twentieth century, the external causal influences, which were determined by the way in which scientific activity functions within society, came to occupy the dominant position in the study of science as a social phenomenon. If certain phenomena or events did not fit in with the traditional sociological analysis, almost automatically they were declared inherently non-social. If we are not dealing with external determination, then we are not talking about social context.

Towards the end of the twentieth century, the picture changed considerably. External causal determination is now receding into the background, and attention is focusing on those personal relations that take shape in the course of acquiring new knowledge. But real difficulties arise. Can one call such relations 'social'? Should we reject the traditional concept of social context, and what consequences might such a rejection entail? Are we changing the very concept of social context too radically?

The source of all these difficulties in the interpretation of scientific knowledge was the prime role accorded to scientific revolution as the most significant, essential aspect in the development of science. This led to a revision of the cumulative model of the history of science, a model in which society and scientific knowledge develop in parallel, each in accordance with its own laws.

### SCIENTIFIC REVOLUTION AS THE DETERMINANT IN THE SUBSEQUENT DEVELOPMENT OF SCIENCE

It would be a mistake to think that historians who supported evolutionist views denied that revolutions occurred in the history of science. Phenomenologically, they recognized revolutionary situations, but assumed that they could be understood only by including them within the continuous flow of development and considering them part of the evolutionary process.

Usually, scientific revolutions were viewed as accelerated evolutionary development or as periods in the development of the natural sciences characterized by the fact that a particularly large number of major discoveries by

outstanding scientists were made in a fairly short period of time.

Another way of understanding scientific revolutions as part of the evolutionary process is to push the revolution itself further into the past during the analysis of the revolutionary situation by discovering an endless chain of predecessors preparing the way for the great scientists who, phenomenologically, then appear as the revolutionaries. In this case, revolution is understood as being not a transition from truth to truth, but from falsehood to truth, from pre-scientific concepts to scientific concepts, i.e. as an absolute principle.

In the second half of the twentieth century, the following important factor was brought to the fore in the interpretation of scientific revolutions: inter-revolutionary periods in the development of science, the study of which had seemed to yield such good results, are difficult to understand without a corresponding interpretation of scientific revolutions, since understanding the cumulative periods depends on this interpretation. It is presupposed that the new theory, which emerges in the course of a scientific revolution, differs radically from the old theory and that this means a transition to an essentially new type of activity. After the revolution, the development of science begins, as it were, from zero.

However, if a theory (or paradigm or research programme) emerges immediately in its integral, complete and perfected form as a model and instrument of activity in the post-revolutionary period, then during this period the scientist will not need to engage in any essential improvement of the new theory, since it is already perfected. It is only necessary to polish the details by successfully resolving questions emerging lawfully within the framework of the new theory. This is precisely the point of view expressed in the concept of T. Kuhn.[1]

In the inter-revolutionary periods, the scientist constantly perfects the superior qualities of the new theory, or slightly transforms that theory, adapting it to explain additional facts. In this case, the work of the scientist after the revolution is focused on the past, on a revolution that has already occurred, and the resulting theory. Science develops by constantly glancing backwards. This approach to scientific revolutions presupposes that all creativity, all effort to discover something new, is concentrated in revolutionary situations.

As for activity in the periods between revolutions, here activity consists exclusively in confirming and polishing existing knowledge and in using this ability as an instrument and a means of resolving problems whose significance is found within the framework of the new theory. The inevitable result is the excessively automated, algorithmic nature of scientific activity during the inter-revolutionary period.

## THE STRONG AND WEAK ASPECTS OF KUHN'S INTERPRETATION OF SCIENTIFIC REVOLUTIONS

Kuhn's position has both a strength and a weakness. On the one hand, he has identified an existing aspect of scientific development. Indeed, the new paradigm or theory is confirmed within the structure of scientific knowledge by subsequent work along the lines of that new theory (and its adaptation) in order to explain a range of new phenomena.

In the history of science, perhaps the most vivid illustration of this kind of development is the Ptolemaic theory, with its ever-increasing number of epicycles introduced to explain newly discovered facts, which render the structure of the theory excessively complex. As regards excessively formalized, virtually algorithmic activity along the lines of a given paradigm, this is a fact, and the strong point of Kuhn's theory is that he analysed such activity, linking it to a particular interpretation of scientific revolution. Everyday scientific research is not conducted in isolation, but is shaped by scientific revolution.

On the other hand, Kuhn's theory reveals a weakness: in directing his attention to precisely these aspects of scientific activity, he has unwittingly gone some way to returning us to the previous line of reasoning as regards the history of science, which argued that the development of science one way or another excludes moments of creativity, which are either moved to the periphery of science or even placed outside its boundaries. Kuhn's concept reveals a clear tendency to view scientific creativity as a vivid, exclusive and rare spark rigorously determining the subsequent development of science, in the course of which the previously acquired knowledge is substantiated in the form of an expanded and confirmed paradigm.

Here Kuhn opposes K. Popper, who places particular emphasis on the ongoing nature of scientific revolutions. Popper views the history of science as an unending chain of revolutions. The sooner any new theory can be proved false and overturned, the more scientific it is, and the more frequently this happens, the more successful is the development of science.[2]

Despite the fact that Kuhn's work undoubtedly contains different aspects of this idea, the basic postulate is nonetheless as follows: the development of science takes place primarily via the normal activity of scientists, whose main aim is to use the paradigm that emerged triumphant from the latest revolution in order to resolve current problems and thus confirm the validity of that paradigm and its advantages in relation to the previous paradigm.

Activity in the course of scientific revolutions is extraordinary, whereas the work of scientists in the post-revolutionary period is ordinary, normal, and it is precisely this work that enables us to distinguish science from other spheres of intellectual activity.

## THE PROGRAMME (PARADIGM) AS A PROJECT FOR FURTHER RESEARCH

Another possible interpretation of cumulative periods is one in which, when interpreting scientific theories, we proceed on the assumption that the theory that emerges in the course of a revolution is still incomplete. This point of view is developed with detailed consistency by I. Lakatos, particularly in his article 'Proofs and Refutations'.[3]

Unlike Kuhn, Lakatos does not believe that the scientific research programme that emerges in the course of a revolution is complete and fully formed. The continuity of scientific research in the post-revolutionary period emerges, in Lakatos' view, out of the lack of clarity in the initial research programme, which appears as a hazy indication for the future. The programme functions as a project for further research and as a project for its own further

development and final formulation. While the research programme is being perfected, Lakatos refers to its progressive development, which ends at some 'saturation point', after which regression sets in.

In the 1960s and 1970s, there were heated debates about the definition of a scientific revolution and its role in the history of science.[4] For all their differences, the ideas of Kuhn, Popper and Lakatos concerning scientific revolution had one thing in common: they were a reaction to the crisis of positivism and positivist concepts in the history of science.

## THE SCIENTIFIC COMMUNITY

The fact that Kuhn pointed to scientific revolutions as moments in the history of science when fundamentally new knowledge is forged inevitably evoked increased interest in the subject of scientific activity, be it relating to the individual scientist, the scientific community, or a research laboratory. The concept of the scientific community was of particular importance to Kuhn. It was the inclusion of this concept into his theory of the history of science that provoked sharp criticism from his opponents. He was accused of irrationalism on the grounds that, instead of providing a logical explanation as to why the scientific community rejects an old theory and espouses a new one, he had advanced social and psychological arguments.

Indeed, his work contains assertions to the effect that the transition to a new theory may be based only on faith in its future fruitfulness, or on some undefined aesthetic sense, that the main component of the convictions held by the scientific community at any given moment are personal and historical factors, apparently fortuitous and arbitrary elements.

The criticism launched against Kuhn over this issue is no accident. Here there is indeed the hidden danger of finding oneself beyond the boundaries of logic and rationality. The main difficulty confronting anyone who conducts research on the scientific community is that there emerges time and again an insurmountable demarcation line between the social relations within the scientific community and the content of scientific ideas.

As a rule, researchers fail to take into account the fact that very diverse forms of social relationships exist within the scientific community. These relationships may be those of superior and subordinate, of scholar and non-scholar, financier and manager, etc. The behaviour of scientists, the motivations behind their activity, the goals that guided their choice of profession and work, are the subject of detailed analysis.

It is important to note that this group of social relationships, although specific to the scientific community as one type of social structure, is nonetheless only very indirectly linked to the content of scientific ideas. Alongside relationships of this type, there is also the method of communication among scientists while discussing and resolving purely scientific problems. Here the scientist functions not as someone occupying a particular position in the hierarchy, nor as someone guided by non-scientific goals, but as someone representing a specific logical position in a given scientific dispute, as a supporter of some scientific theory or paradigm.

If one analyses a situation linked to the development of scientific ideas (for example, the situation of a scientific revolution), then in their debates with one another the scientists, as it were, personify various methods of logical interpretation. Here the test of whether or not a given scientist is expressing in his scientific argument what is indeed a logical position, and not subjective features of his own personality irrelevant to the development of science, is the possibility of replacing the scientist with a fictional character, as in the 'Dialogues' of Galileo, or the 'Proofs and Refutations' of Lakatos.

If there is no serious consideration of these distinctions, it will hardly be possible to arrive at a solution to the central problem that appears in the work of Kuhn and his supporters, namely how to avoid relativism, that is, changes in scientific knowledge when moving from one scientific community to another, from one set of social conditions to another.

## MICRO-SOCIOLOGICAL RESEARCH

The sociological science of the 1970s and 1980s absorbed many of Kuhn's ideas, and above all this meant rejecting rigorous demarcation lines between society and knowledge. Supporters of externalism, in particular R. Merton and his school, were of the opinion that the science historian and sociologist should not and cannot analyse scientific ideas. They recognized the need for a philosophy of science, whose object of study differs from that of sociology.

The new generation of sociologists, however, believes that only sociological methods can be used to study scientific knowledge in all its aspects and that sociology embraces all the issues of the philosophy and logic of science. These ideas are supported most consistently by representatives of micro-sociology. In their view, the products of scientific activity should not be seen as grasping and reproducing something that exists in the natural world. In fact they are forged, constructed and transformed in the laboratory out of whatever is at hand.

K. Knorr-Cetina, one of the most striking representatives of the concept of micro-sociology,[5] describes the relationship nature–scientific knowledge as external for science and unimportant in terms of understanding it, while social relations within the laboratory are internal for science and express its essence. In the opinion of Knorr-Cetina, theory as a product of scientific activity is a specific construction bearing the stamp of situational fortuity and the structure of interests involved in the process that gave birth to it.

The products of science cannot be adequately understood without analysing the process of their construction. This means that what happens in the process of their construction is relevant to the results obtained. It also means that the products of science should be seen as internally constructed in the process of production, independently of the question of their external structuring via verification of their correspondence to reality.

This initial postulate immediately excludes from Knorr-Cetina's discussion of science the cognitive relationship between man and reality. The activity of scientists in the laboratory, which for Knorr-Cetina is the embodiment of all science, forms a closed circle with no exit into the external world as an object of cognition. Scientific results, including empirical data, are described as being above all the result of

the production process, which includes chains of decisions and discussions and presuppose the need for selection. Each selection is made on the basis of the previous group of procedures for selection and, in its turn, becomes the basis for subsequent selections.

The complexity of the scientific constructions, which appear as a result of the various selections made by scientists in a particular laboratory, prompts us, argues Knorr-Cetina, to consider it highly unlikely that the products of scientific activity were obtained by the same method used in diverse circumstances. This means that it is highly unlikely that the process of production of the result could be repeated. This would become possible only if most of the procedures of selection were rigorously fixed or implemented in a similar fashion. Any novelty in science is seen by Knorr-Cetina as the result of social interaction and discussion. Innovation and its acceptance, according to Knorr-Cetina, are moments of temporary stabilization within the process of constructing knowledge, a process which is basically social. In contrast to Merton, Knorr-Cetina does not recognize that gnoseological issues have any right to exist outside the laboratory. In her opinion, her sociological analysis comprehensively covers all aspects of science, and is self-sufficient.

## 'MINIATURIZATION' IN RESEARCH INTO SCIENCE

The tendency on the part of sociology to absorb the subject matter of the philosophy, gnoseology and logic of science was strikingly apparent at the end of the twentieth century. Moreover, the consolidation of this tendency is linked to the 'miniaturization' of the object of research. As we have seen above in the case of Knorr-Cetina, the object of research is not relationships between, for example, science and the culture of a given epoch, its production, its social system, but relationships between the scientists themselves in a given laboratory. If it is a question of disputes and arguments, the researcher is interested not in fundamental scientific revolutions dealing with the problem of changing the manner of thinking and the picture of the world but in fairly mundane situations involving the solution of immediate questions in a given branch of science. The related discussions embrace the entire range of possible relations within the scientific community.

In his article 'The Political Anatomy of Controversy in the Sciences',[6] the American historian E. Mendelsohn attempts to substantiate the sociologization of scientific controversy. Here, in his opinion, it is not a question of social arbitrariness invading the sphere of purely scientific rationality in the study of contradictions and disputes, but a question of normal scientific activity and the procedure of selection, which is structured and organized by a fortuitous goal orientation. In a situation of dispute or conflict, the characteristics of the most ordinary behavioural procedures of scientific activity become more noticeable. In Mendelsohn's opinion, the authors of the reconstruction of many scientific debates reduce them to abstract content and make only occasional references to the personalities drawn into the disputes. For the most part, only the cognitive structures remain the focus of attention. In reality, however, the nature of the ending of the dispute, if closure in fact occurs, is shaped within the context of competing interests.

In the title of a collection of articles that includes the article by Mendelsohn, we find the concept of 'case studies' (*Scientific Controversies: Case Studies in the Resolution and Closure of Disputes in Science and Technology*). This concept is very important in understanding the nature of the development of science at the end of the twentieth century. By the 1970s, research in the form of case studies has become fairly widespread. In 1971, P. Forman published a long article entitled 'Weimar Culture, Causality and Quantum Theory',[7] which can be considered fairly typical of this kind of research. In 1979, M. Mulkay published the book *Science and the Sociology of Knowledge*,[8] in which he devoted considerable space to a description of case studies. During the 1980s and 1990s, case studies became a fairly common form of research.

## NEW FORMS OF RESEARCH INTO THE HISTORY OF SCIENCE AND FUTURE PROSPECTS

In case studies, the aim is to understand a past event not as something incorporated within a single line of development and possessing certain features in common with other events, but as something unique that could not be reproduced in different conditions. In the earlier type of historical work, scholars sought to study as many facts as possible, in order to discover something in common, and on this basis, to identify common laws of development. At present, the historian studies a fact as an occurrence and as the concurrence of many specific features of the development of science coming together at one point in order to distinguish it from others.

This raises the question of what is to become of the theoretical aspect of historical studies. Can we speak of the logical nature of a historical reconstruction if the result of the historian's work is the reconstruction of a unique event? How are we to understand the concept of the universal in history? Can we speak of the universal nature of historical research of this kind? Insofar as the individual and specific has always been understood to be the opposite of the logically universal, case studies were generally seen as empirical, and all the more so since, as a rule, case study authors themselves give little thought to the specifics of their own work. Case studies have spread somewhat spontaneously and not as the result of a deliberate methodological reorientation on the part of historians.

One cannot ignore the fact, however, that the historical reconstruction of a past event as something unique presupposes complex theoretical work of generalization in order to construct an integrated, three-dimensional event that brings together all its most diverse aspects. A mere photograph can in no way be a substitute for such a reconstruction: both logically and theoretically, this is no less complex a task than the universalization of historical facts and the identification of their common characteristics. The aim should be to elaborate the principles to be used to identify the universal in history via the study of unique, particular events.

Nonetheless, case studies should not be considered a completely novel form of historical reconstruction, for research of this kind has always existed. Here we are speaking of the predominance of a certain type of research and the fact that case studies have now come to the fore.

Research of the cumulative kind will also continue, for it reflects such important features of the development of science as the dependence of each new step forward on the previous level of development and the increasing volume of knowledge. It is simply that these features of the historical process are gradually losing their prime significance and are today slipping into second place as a result of changes in the type of theorization.

Let us look at some of the methodologically significant features of case studies.

First, such research concentrates not so much on a certain fact, some final result of scientific discovery, but rather on the event itself and, as far as possible, on its unique and integrated nature. Whether the researchers themselves realize this or not, these easily visualized events are clearly defined crossroads at which different lines of research into the history of science intersect, be it the analysis of the creative process, of social conditions, the correlation of society in general or the structure of scientific knowledge. Case studies are syntheses of the general and the particular, and the easily imaginable, concrete nature of the event under examination.

Second, it is very important for case studies to be a very delimited event; it is not, as a rule, the culture of some lengthy period in history or the culture of a large region. The objects of study are localized events, such as an individual text, a scientific dispute, conference materials or a scientific discovery by a particular team of scientists.

Third, it is particularly significant that case studies can be described as being a kind of a funnel drawing in both previous and subsequent events, although the object of study is contemporary science, is 'now', even if this 'now' relates chronologically to past ages.

Science historians have always wanted to know how individual creativity – the unique situation in which a new theory emerges – can be integrated within the general laws of the development of scientific knowledge. The previous chapter looked at how this question was resolved in cumulative concepts of the history of science. However, the use of general theoretical postulates always proves far from simple in practice.

The mid-twentieth-century crisis in the positivist methodology of science led to the formulation of the concept of 'system of thought' or the type of thinking of a given epoch (especially in the works of A. Koyré and T. Kuhn). Here the historian makes use of such concepts as particular and unique. Scientific thought is integrated into the context of culture in, for example, Antiquity, the Middle Ages or modern times. Moreover, the Middle Ages are no longer seen as a preparatory stage for modern times or as its pre-history or cause, but as an epoch having its own historical significance.

It is here that the single line of development breaks down. Different cultures are correlated to each other as coexisting at the same time, each illustrating its uniqueness. The fact that Shakespeare lived after Aeschylus gives him no advantages as regards the evaluation of his work. In science, it is more difficult to use this approach, since advance and progress in development, and its cumulative nature, are particularly evident. However, such a methodology of research is possible if science is viewed in a cultural context. Research into science of the kind conducted in case studies is a serious attempt to advance the study of science in precisely this direction.

## PHILOSOPHY AND RELIGION AND THEIR RELATION TO SCIENCE

In elaborating the concept of scientific revolution in the historiography of science (A. Koyré or T. Kuhn), emphasis was placed on the fact that, if the scientific revolution is indeed radical (such as the scientific revolutions of the seventeenth and twentieth centuries), then its basic meaning lies in the elaboration of the philosophical basis of science. The philosophy of the seventeenth century formulated that basis of thought which made scientific research possible: the corresponding concepts of cause, motion, time, space, etc. Philosophical thought constantly asks how science is possible and seeks to find grounds for this possibility. Science of itself ('normal science', to use Kuhn's terminology) does not deal with questions relating to its own justification. The natural scientist puts aside philosophical disputes regarding the founding principles of science and seeks solutions to his or her professional questions. The solution of strictly scientific questions is possible because the basic conditions of scientific activity as elaborated by philosophy are accepted without question. Thus philosophy provides the inner impulse to scientific development, and its principles are invisibly present in scientific ideas and theories, becoming an object of discussion only when they cease to function and when they become an obstacle along the path of further scientific development. And this is precisely what occurred in the early twentieth century. Science philosophized: major natural scientists immersed themselves in philosophical disputes over the nature of causality, time, space and the elemental.

Thus, science in its 'pure form' does not wish to be involved with philosophy, which is an impediment. Yet at the same time, scientific activity is only possible because philosophy has done preparatory work to elaborate the principles of scientific activity. However, scientific activity itself, as it develops, leads to a situation in which the initial philosophical principles cease to function and require renewal, and scientific research requires philosophical thought. In this way, science reveals its philosophical interior.

In those moments of scientific activity when the scientist puts philosophy aside, when philosophy impedes him, he often relies on religion or a religious attitude to the world. Religion serves as a support in such cases and helps him to orient himself in the world and justify his existence as a scientist. Religion does not provide an answer to the question of the truth or falsehood of given scientific theories seeking to explain the construction of the world. If science sees the world as something eternal and invariable, without having any interest in the question of its purpose, religion is interested in how the world was created, and for what purpose. This is the dividing line between religion and science. One might say that they are 'uninterested' in each other's questions.

However, the scientist is not simply uninterested in religion. He needs religion, and here one may note several points.

1) Philosophy questions the original principles, discussing them endlessly. Philosophy is a risky occupation that puts the mind in doubt. The scientist, however, cannot work on the basis of such uncertainty. He needs stability, and it is precisely religion that enables him to believe in eternal principles. For normal scientific research, such faith is essential.

2) The scientist treats the world as something pre-existing. The world is perceived by the scientist via his senses, and it is important for him to be sure that this is not an illusion or a mirage and that the world exists not only for him and his human perception. Religious truth lies in the creation of the world and the purpose of that creation. The world has been created, therefore it exists. This kind of religious belief in the existence of the world as a created phenomenon assists the scientist in his activity. The world exists not only for him, but also for God; that is, the world exists in reality.

3) Man cognizes the world with his intellect, and it is important for him that the world not be chaotic. He needs intuitive confidence in the harmony of the world. The world not only exists, but is also organized on the basis of laws. Such a cosmic religious faith facilitates the work of the scientist. Confidence in the existence of the world, its harmony and the stability of its founding principles is important for the very existence of science.

This, in general terms, is the attitude towards religion that predominated in the twentieth-century both among science historians, and natural scientists. The notion of the hostility between science and religion does not enjoy popularity, and this is true both as regards R. Merton and S. Jaki, who have undertaken particularly extensive research into the role of religion in the history of science.

**Protestantism and science in seventeenth-century England**

Merton analyses the historical situation in England in the seventeenth century, when the development of science was promoted both by industry and the new religious movement of Protestantism. In the preface to the second edition of his book,[9] Merton expresses a certain perplexity over the fact that it is precisely the relationship between science and religion, and not science and industry, that attracted the greatest attention on the part of the critics. Merton explains this as the result of the fact that his method of interpreting the relationship between science and religion differs considerably from the positivist explanation. The positivists (Merton refers in this regard to J. Draper and A. White) believed unquestioningly that this relationship could only be one of conflict and that a state of war between science and religion was inevitable.

Such conclusions were usually made on the basis of two kinds of facts. In the first place, there are historical facts that time and again confirm the hostility between science and religion, for example, the burning of Giordano Bruno, or openly hostile statements by religious leaders directed at science. The second type of facts involves the opposing nature of the dogmatic postulates of theological knowledge and the tendency of scientific research to bring everything into question. Merton does not deny either historical facts or the opposing nature of the theological and the scientific approach to the world. The possibility of contact between science and religion is based, according to Merton, on the nature of ethical norms. Protestantism unwittingly promoted the consolidation of science as a social institution despite its theology as a particular way of perceiving the world and despite the views of its leaders.

Protestantism was by no means the only possible social institution capable of assisting the emergence of modern science. It so happened that Protestantism was science's greatest, though not its only, support at that particular time and place. However, it might well have been that, in some other case, another social institution could have played the same role; it is a question of a particular combination of circumstances.

The social values characteristic of Protestantism meant that it approved of science by virtue of its deeply utilitarian orientation, concealed behind religious terminology and approved by religious authority. It validates those who have glorified themselves in 'good works' based on the desire to be useful to one's neighbour and to society as a whole. The utilitarian principle governed practical activity, and this brought Protestantism close to the rest of culture. Of particular importance in the social evaluation of science and technology was the Protestant tendency to praise the faculty of reason. Reason is worthy of praise as man, who is alone in possessing this quality, is made in the image of his maker. Reason is a means of bringing sensuousness and sinfulness under control. Reason enables men to praise God by perceiving the greatness of his creation. Protestantism as it were demonstrated the absence of any incompatibility between these two great values – reason and faith.

The main prerequisite of modern science, in Merton's view, is the widespread instinctive conviction in the existence of a 'natural order.' For Galileo and Newton, the ultimate criterion of the truth in science is experiment, but the very concept of experiment proves untenable without the original postulate that there is a natural order and that if one asks the appropriate questions, nature will supply the answers. This postulate is definitive and absolute, and expresses faith in the possibility of the existence of science as such. However, this kind of conviction, although it is an essential prerequisite of the emergence of modern science, cannot bring about scientific development. This requires a permanent interest in seeking to discover this natural order by not only rational but also empirical methods, that is, an active interest in the world together with a specifically empirical approach. In the form of Protestantism, religion created the conditions for the emergence of this interest. Protestantism insisted on active secular activity, with an emphasis on experience and intellect as the basis of action and faith.

## THE RATIONAL LINK BETWEEN CHRISTIANITY AND SCIENCE

In his analysis of the significance of religion for science, S. Jaki, a Benedictine monk and science historian, emphasizes in particular that Christianity is linked to belief in the individual, the rational, and the absolutely transcendental lawgiver or creator.[10] This is the Christian concept of God, which generated faith in the rationality of the world, in progress, and in the quantitative method, all of which are the component elements of scientific inquiry. In Jaki's thinking, a major role is played by the concept of 'natural theology', which he understands as following the path along which the human mind is confirmed in its knowledge of God. Science, historically and philosophically, provides a logical basis for understanding the work of God. Science deals with a basic issue: what kind of world is

needed if man is to be able to cognize it? Or, what should nature, including man, be like, if science is to be at all possible?

When Jaki writes of the need to give our utmost attention to the principles of science, he means that these principles cannot be understood outside the context of philosophy and religion. On its own, science is not able to answer the question of why science is possible. Closest to Jaki's concept is Duhem's theory that the origins of modern science derive from the Middle Ages. For Jaki, it is important to stress the fact that science did not begin with Galileo, and that 'medieval' means 'Christian.' In the Middle Ages it was considered beyond all doubt that the universe had been created freely and rationally, and it is only such a universe that is open to scientific investigation.

Delimiting fairly rigorously the sphere of the 'positable' in science (the scientist should not doubt the reality of the universe, its causality and rational organization, its creation by God), Jaki examines all scientific discoveries from the same viewpoint, that is, the extent to which they go beyond the positable within science. As a result, Jaki often finds himself in an ambiguous position: on the one hand, he praises science as being divinely blessed, while on the other, he is obliged to reject a whole series of scientific ideas and theories comprised quite organically within the structure of scientific knowledge, such as the idea of infinity, Darwin's theory, the uncertainty principle, the theory of the tunnelling of alpha particles, and the anthropy principle, among others.

The theological views of Jaki are extremely rationalized. He constantly emphasizes that the rational paths offered by science lead to God. Moreover, he believes that God gave man his intellectual faculties so that he might secure his conviction of the existence of God by purely rational means. Therefore, Jaki looks at all scientific achievements primarily in terms of the extent to which they testify to the existence of 'God the Creator'. The central question in science concerns the relationship of scientific knowledge to God, and it is difficult to say which line of thought dominates in Jaki: is it the scientist created by God in his own image and likeness, or is God, as imagined by Jaki, in the image and likeness of the scientist?

In Jaki's thinking, religion becomes so rationalized that the concept of faith virtually disappears. The existence of 'God the Creator' is not something one has faith in, but rather it is something to be proven logically with the aid of science.

## CONCLUSION

The main changes in the philosophy, sociology and history of science in the twentieth century were linked to the crisis in positivist philosophy in the mid-twentieth century. The very founding principles of knowledge about science, which until then had been accepted axiomatically, as not requiring discussion, appeared in a new light. In certain areas these principles were clarified and formulated more precisely, and certain features became even more convincing when seen from this new angle. Other features were reappraised and questioned, and some foundered, leading to a sense of disorientation and confusion.

During the period of crisis, many things came to be viewed differently following a study of the theoretical and social aspects of scientific revolution, and the dominant object of study – the consistency and continuity of scientific development – appeared in a different perspective. Indeed, never had the progressive and cumulative nature of scientific development been subjected to such detailed discussion and analysis. There are few researchers who would venture to deny that modern science possesses these qualities. However, certain problems arise. For example, how is the continuity of science to be combined with the inevitability of scientific revolutions, when scientific knowledge undergoes a radical change? How is the transition from pre-revolutionary to post-revolutionary knowledge achieved? Can this transition be explained rationally, or is the single thread of scientific development in fact divided, each period in the history of science having its piece, in no way connected to the others? How are we then to explain the vectorial nature of the development of scientific knowledge?

Or let us take the question of the social context of science. One can scarcely doubt (and virtually no one does) the massive influence that external social factors have on the development of scientific ideas. However, can it be viewed as decisive during periods of scientific revolutions? Can the process of the emergence of a new scientific theory be determined by external economic, political, military or other factors? The answer given by most researchers, whether directly or indirectly, is 'no.' The very idea that we can ignore external social factors when analysing scientific revolutions and such factors as the appearance of anomalies in theoretical knowledge, or the emergence of a competing theory and its conflict with the old one, force us to respond negatively to this question.

Thus the previous concept of the basic mechanisms of the social influences operating during scientific revolutions no longer holds, and this obliges us to look at them from a new angle, to ponder the specific features of their operation within society and to define the boundaries of their effectiveness in the development of scientific knowledge. Moreover, a clearer and, one might also say, more profound interpretation of external social factors in science inevitably follows from any comparison with other forms of the social context within science. These factors have become a direct object of investigation together with scientific revolutions, leading to particular interest in the study of the scientific community engaged in producing new knowledge and the appearance of a new type of research known as case studies.

To the extent that, in the twentieth century, science is one of the most important components of the social, public and cultural life of all the regions of the world, the problems addressed above are being actively discussed by scholars around the world. However, it should also be remembered that science has its own specific features in the context of, for example, Oriental cultures, where philosophy, religion and social order have shaped the traditional development of natural science through the centuries. Moreover, these traditions live on and now require special analysis. In this connection, we must mention the British science historian J. Needham, who devoted many years to studying science in China.

In Eastern Europe and the Soviet Union in the twentieth century, the social, political and ideological conditions were such that direct contact with Western scientists was very difficult. Soviet research into science continued energetically, but to a large extent it functioned in isolation, and contacts

with Western colleagues were often of a purely official nature. Both the issues and the lines of research were often determined by various ideological considerations. Soviet scholars were unable to join the Western confraternity of sociologists, philosophers and historians of science. Their work should now become a special object of study. Let it suffice to say that in the Soviet Union there was a strong school of philosophical interpretation of science and its history as represented by the works of V. S. Bibler, P. P. Gaidenko, and M. K. Mamardashvili. Research into the internal logic and system of science was undertaken by V. N. Sadovsky, V. A. Smirnov and others, while the methodology of science and its history were explored by V. A. Lektorsky, S. R. Mikulinsky, V. S. Styopin, and many others.

The tendency to identify unique features of science, which appeared towards the end of the twentieth century, obliges us to avoid seeking to standardize the enormous and diverse worldwide range of approaches to understanding science as a social and cultural phenomenon.

The improvement of methods of communication among scholars, thanks to technological developments and the computerization of all spheres of life, is leading to the creation of larger teams of scholars from different countries and continents. The corresponding terminology has also appeared: now we speak not of schools, which are usually associated with particular universities, institutes or laboratories, but about worldwide colleges, problem groups, scientific communities. Scholars are united by a given issue and common research interests. Science is being internationalized.

# MEDICINE AND PUBLIC HEALTH

*Jean-Charles Sournia*

The spectacular progress achieved during the twentieth century in many branches of medicine, in terms of diagnostic and therapeutic tools and pharmaceutical and surgical strategies, should not lead us to underestimate the extent to which attitudes towards the health of nations have also changed. The concepts of public health and social medicine developed during the first half of the nineteenth century first in Britain, and subsequently in France, but it took a long time for these ideas to be put into practice. None of the doctrines devised ever led to the immediate establishment of a system to protect the population from various health risks. The few rather partial measures taken focused mainly on the cities (since the countryside was thought to be a healthy place) and on collective groups such as the army (in France, in 1852).

Despite the findings of Pasteur and Koch, it was only after the turn of the century that European governments actually recognized that infectious diseases were contagious. The inauguration of the Office International d'Hygiène Publique (OIHP) in Paris in 1908 was a long-awaited event that took fifty years to materialize. This meant, however, that it was at last possible to set up international cooperation between the various gradually developing national health services.

We propose to outline in the present article the complex history of public health in the world (except Asia). Technical developments in the field of medicine will be alluded to as briefly as possible, since their story has been told elsewhere.

## 1914–1940: A PERIOD OF CONTINUATION

### The effects of the First World War

Many countries took part in the global conflict of 1914–18, which split the world into two. The spirit of international solidarity did not disappear completely, however, since the countries engaged in the hostilities continued to submit public health reports to the OIHP throughout the war.

As commonly occurs in times of war, epidemics were rife during this period, for several reasons. First, there were the troops moving from one place to another: the Allied armies received reinforcements from North Africa, sub-Saharan Africa, India, Indochina, Canada and Australia, and American troops were also sent to France. Secondly, whole populations migrated from northern to southern Europe and from east to west. And lastly, in times of war, administrative structures are relaxed, and the regulations relating to matters of health are not applied strictly. For practical reasons, it is difficult for the population to apply the basic rules of hygiene. This explains how typhoid fever devastated the Austro-Hungarian army and spread throughout the Balkans. The French and German contingents were better vaccinated. The Eastern European countries were ravaged by typhus until the 1920s, just as they had been one century earlier at the time of the Napoleonic invasion. They were also swept by epidemics of typhoid, cholera, dysentery and malaria.

No doubt due to the arrival of the North American troops in France, a wave of what the French called 'Spanish flu' began to work its way through Western Europe at the end of 1917. It spread among the armies and all levels of civilian society, probably causing up to a million deaths. Those who caught the disease either died of pleuro-pulmonary complications or continued to suffer from secondary purulent pleurisy up to the end of the 1930s. When the troops were demobilized at the 1919 Armistice, the influenza was transported to the southern shores of the Mediterranean. The virus is now known to have been related to the porcine influenza virus, which is still endemic in the Western world.

The state of war made it possible for public authorities to take increasingly firm public health measures. The efforts made by administrations in Britain, Germany and France during the previous century to promote public health had come up against some resistance from those who claimed that it was contrary to individual human freedom and the right to self-determination. These arguments tended to seem less convincing under wartime conditions. The public health laws voted in France in 1902 and 1905 were vigorously enforced, and even the most recalcitrant town councils were eventually obliged to open a public health office. The state asserted its authority at the end of the war both in Britain,

where a Ministry of Health was set up, and in France, where an independent Under-Secretary of State was appointed in 1920.

In the various countries, a multitude of private charitable organizations were created for the benefit of wounded soldiers, civilian populations, refugees from places badly damaged by the war, women who had been working in the factories, orphans in distress and other groups. The Red Cross Societies were busier than ever before.

The amount of mutual aid from which the Allies benefited made spectacular strides. In the Balkan countries, the work of the expeditionary forces' medical services consisted largely of helping the civilian populations suffering from epidemics and food shortages: these countries had become only recently independent and were too impoverished to be able to quickly set up the requisite administrative and medical structures on their own.

The United States, for its part, was helping the invaded countries. On the French front, the United States financed the equipping of ambulances, one of which was manned by the Nobel Prize winner Alexis Carrel, who developed new methods of treating infected war wounds. As soon as the hostilities came to an end, the Rockefeller Foundation distinguished itself in Europe in the campaign against tuberculosis and participated actively in informing the public about hygiene.

### Fighting infectious disease

Since the relative success of the battle against infection within the contending armies was quite encouraging, the early measures designed to protect the civilian population before the conflict were further extended during and after the war. As previously occurred in France in 1902, lists of diseases that had to be declared were disseminated in several countries, and medical inspectors were made responsible for collating the numbers declared, so that the Western nations were gradually able to publish coherent health statistics. Systems of public health administration began to be set up under the aegis of specialized ministries.

These measures were more drastic in France than in most other countries however, since the entire French population was vaccinated against smallpox. Most other countries refused to make vaccination compulsory for the sake of individual freedom of choice, but nevertheless used persuasive methods to ensure that vaccination was widely adopted or made it mandatory for some collective groups, such as the armed forces and school systems.

Vaccines of several other types were also used at that time: the tetanus vaccine was not much in vogue, but vaccines of two other kinds, which were widely used in both the more backward and the more modern parts of the world, were to have decisive effects on public health. The first of these was the anti-typhoid and paratyphoid vaccine. It was widely recognized by that time that these diseases were transmitted by drinking water, and vast public campaigns were launched to encourage people to be vaccinated, but something also had to be done to improve the quality of the water supply. City water supplies began to be chlorinated (this method had actually been tested during the war by the city of Verdun). The main improvement consisted, however, of extending the water supply networks. Despite the outstanding examples of innovations made in Britain and

Germany beginning in the nineteenth century, many towns elsewhere were not equipped with properly organized general water supply systems. The town councils were providing workers' tenement blocks with only outdoor drinking fountains.

As the number of public pipelines laid down by either public or private agencies increased, the bacteriological quality of the water was improved by the water companies responsible, under the control of the administrations. The number of uninspected privately owned wells decreased.

In addition to the progress achieved in the distribution of healthy drinking water, the problem of sewage disposal arose. Many improvements needed to be made, and too many built-up areas were using their own neighbouring rivers as sewers. In this respect, the situation took longer to improve, and in 1940, many European and American cities were still not properly equipped: this was so in the case of Lyon, the second-largest French city, for example, which is situated on the banks of two large waterways with fast, regular rates of flow.

The second vaccine to have decisive effects, particularly on the infant mortality and morbidity rates, was the diphtheria vaccine. This type of vaccination was widely adopted by families, even in the absence of any legal obligation, and the incidence of this disease decreased conspicuously in places where children gathered.

The decline of this disease went hand in hand with a sharp increase in the numbers of public and private institutions devoted to protecting children. This trend reflected a change in the public's attitude, which began at the end of the previous century and showed an upsurge after the First World War. The war had led to the expansion of the industrial suburbs, along with the attendant insalubrious, overcrowded housing conditions; despite the increasing numbers of nursery schools and dispensaries and the intense activity of charitable organizations, new-born infants and young children were particularly hard hit by the food shortage that occurred in Germany in the 1920s and by the famine that ravaged the Soviet Union.

Much attention was also beginning to be paid to maternal health care. Contrary to the general rule, according to which women gave birth in their own homes, many maternity homes were built at that time in the form of either small private establishments or public hospital wards. Childbirth was becoming safer in the hands of experienced medical staff. Since the introduction of sterile conditions and antiseptics, epidemics of puerperal fever were no longer to be feared. Maternity homes were opened for women in need and unmarried mothers, and the improved level of family hygiene made it possible for bottle-feeding to be widely adopted. Despite the intensive propaganda circulating in favour of breast-feeding, newly delivered mothers were not always able to provide their babies with their full nutritional requirements. Clean bottles and high-quality manufactured milk substitutes would soon be taken for granted. During the period between the two wars, infants no longer died of malnutrition in most European countries, and the profession of wet nurses and its promoting organizations were phased out. Many efforts were made to protect women and children. In the framework of compulsory school attendance and the development of schools, school health departments were created.

The hardships of the war increased the incidence of tuberculosis. Many people caught the disease, with a mainly

pulmonary focus, and in the towns, people at all levels of society were struck. It is generally held that the epidemic reached its peak in Britain, followed by France and Germany in the nineteenth and early twentieth centuries, and that tuberculosis was spontaneously in decline by mid-century. Whether or not that is an accurate picture, contagion was still running rife at that time in all European and North American countries.

A vast international campaign was launched to promote the elementary rules of hygiene as a means of preventing contagion. The populations were informed via many channels: at school, by means of bills posted on walls and billboards on public transport vehicles, and in public talks given by itinerant charitable associations.

In some countries, the strategy adopted was vaccination for all with the Calmette-Guérin bacillus (BCG), while others were more wary or refused to follow suit on the legitimate grounds that vaccination did not afford absolute protection. The scientific debate on the issue became even more heated when several children died in the 1930 Lübeck accident, due to the use of an improperly prepared vaccine. Open-air sanatoriums and preventoriums were instituted for children from insalubrious areas and those already showing alarming signs of primary infection. X-ray methods were by then available for detecting pulmonary lesions at an early stage, and intensive screening campaigns were organized on the theme 'early screening is the key to a quick cure'. Some sectors of the population were made to undergo systematic lung X-ray examinations, and specially equipped vans tested people at places of work and schools. This was the first time in the history of public health that medical testing had been carried out on groups of people, regardless of their state of health.

Lastly, for the sake of those whose expectoration was found to contain tubercular bacilli, special establishments were opened in places where the fresh air was reputed to favour recovery, at high or medium altitudes, by the sea or in pine forests, so as to reduce the risk of contagion. Patients with tuberculosis were therefore moved to these sanatoriums from their usual surroundings so that they would not contaminate other people; they were treated with restorative drugs, by inducing intra- or extra-pleural pneumothorax, and by performing thoracoplasty. Such medical and surgical methods were designed to give the affected lung a rest.

**Health care and social welfare**

The principle on which the above-mentioned techniques were based was not new, since it had been invented by Forlanini before the First World War. The lack of appropriate therapeutic innovations was actually one of the hallmarks of this period in the history of medicine.

Surgeons certainly had plenty of scope for showing their dexterity and technical know-how, especially when operating on the limbs and the abdomen, thanks to asepsis and anaesthesia. They were less adventurous when it came to performing intra-thoracic and brain surgery, however. Physicians, on the other hand, recorded relatively little progress.

The one outstanding event was Roentgen's 1899 discovery of X-rays, which made possible spectacular strides in the field of medical diagnosis. Never has any scientific discovery spread so quickly throughout the world without causing any controversies or squabbling among various schools of thought, but consistently arousing admiration and enthusiasm for its many possible applications. It was henceforth possible to explore all the organs in the body from the outside.

In the field of chemistry, new and never-imagined vitamins and hormones were discovered, which led to the identification of human diseases resulting from the insufficiency or excess of these indispensable substances. It was not until the end of the 1930s, however, that some original therapeutic molecules were discovered, thanks to the fact that the main aim of the research workers at that time was to find means of fighting infectious diseases: the first sulfonamides capable of destroying dangerous germs in humans were manufactured in Germany and France. At the same time, A. Fleming had discovered that penicillin, which is produced by a living organism, was capable of preventing other organisms from developing; some time went by, however, before this discovery reached the practical application stage.

Steps were taken by surgeons and mainly private companies to set up medical establishments, maternity homes and surgical clinics, such as the cancer clinics at which famous surgeons received visitors and treated patients from all over the world. Only the poor frequented the public hospitals: a sharp distinction was also made in every country between those who could be tended in their own homes and the others. Poor people went to public establishments, while the more better off tended to seek treatment at private ones, which tended to be more comfortable and better equipped.

To combat this segregative tendency, efforts were made in some countries to develop various social welfare systems to protect the least privileged members of society. The first steps on these lines were taken by Bismarck in Imperial Germany back in the 1880s, when a sickness insurance fund was created for industrial workers, along with special occupational accident risk coverage. Although these regulations involved only some categories of workers, they were subsequently adopted in many European countries and gradually extended in the 1930s to include other categories of beneficiaries, whereas the United States was quite opposed to social welfare of this kind. The period also witnessed the opening of dispensaries, where needy citizens could be screened or treated for tuberculosis, venereal disease, etc.

The Soviet Union adopted a different strategy not involving health insurance. Based on an ambitious programme, free health care was dispensed to all the populations within the Union, including the inhabitants of the destitute Central Asian republics. Other aspects dealt with in the USSR included hygiene campaigns, various occupational health initiatives and efforts to eradicate tuberculosis.

Another form of family aid came into being. Since many young men had died during the war – in France, one and a half million men of procreative age had been killed – some governments, starting with France, followed by Italy and Germany, implemented policies encouraging childbirth. Families with several children were provided with financial aid in the form of family allowances. This system, which has meanwhile been adopted and maintained in many countries in the world, is designed to incite people to have larger families. Whether this aim is always achieved still remains

to be proved, but in any case, these cash allowances are always welcome in needy households.

## International efforts

The previous century showed how effective international cooperation could be in combating severe contagious diseases. The global conflict did not lessen the truth of this statement. The countries involved in the First World War were not affected by any of the three terrible diseases with which the nineteenth century had been so obsessed: the plague, cholera and yellow fever.

The first few decades of the twentieth century were marked, however, by a plague epidemic, which did not spread beyond Eastern Asia. Several medical teams fighting the disease met up in Manchuria. Europe was hardly affected at all by the plague epidemic, apart from twenty or so isolated cases contained within a Paris suburb, which came to be known as 'the rag-trade epidemic', and never spread elsewhere. On the other hand, cholera was still endemic in the Indian subcontinent.

In medical circles, the terms 'hygiene' and 'public health' were considered synonymous. Ensuring the health of the population meant abolishing epidemic diseases. Future doctors had to be trained in this new discipline, and two different solutions were adopted for this purpose. In Italy, Germany and France, university chairs were created for the study of hygiene at the medical faculties. The Anglo-Saxon countries opted rather for setting up specialized institutions: the Johns Hopkins School of Hygiene was founded in Baltimore in 1918, and the London School of Hygiene and Tropical Medicine in 1929.

The war also proved the solidity of the colonial empires founded by Britain, France, Italy, Belgium, Portugal and the Netherlands (the German dependencies were redistributed when the peace treaty was signed). The colonial medical services were not only good observers of the state of health of the countries they occupied (which contributed to promoting the worldwide communication of medical information); they also took an extremely active part in improving the health of the inhabitants of these rather backward countries. They made use of all the preventive measures at their disposal: vaccination and public information campaigns, reducing the incidence of parasitoses and improving hygiene in towns and encampments.

At the instigation of the countries concerned, schools of medicine were often founded in Africa, India and the Far East, thereby resulting in fully trained doctors or health officers who were in close touch with the native population and familiar with the traditional local customs.

It was largely thanks to the colonial regimes that several dozen institutes were created throughout the world for the purpose of carrying out research on the identification and prevention of bacterial and parasitic diseases. In Latin America, Africa, the Far East, and the Soviet Union, some of these institutes were dignified with the name Pasteur and some of them were actually placed under the aegis of the Institut Pasteur in Paris.

The OIHP continued to collect and disseminate epidemiological information through the two world wars up to 1946. The creation of the League of Nations, despite its 'Health Organization', did not detract from the usefulness of the OIHP. Not all countries joined the League of Nations, and the Soviet Union took part in its activities only episodically. After gaining membership with some difficulty, Germany left in 1933, and Italy was practically expelled after occupying Ethiopia, the only African member country. As for the United States, which failed to follow President Woodrow Wilson's principles, it never became a member at all. It continued its membership in the OIHP, and continued to run the Pan-American Health Office in Washington, which it controlled.

The League of Nations then began to undertake missions on a larger scale than those of the OIHP. The original 'Epidemics Commission' became the 'Health Organization', which gradually acquired international responsibilities. It was decided that the regional offices in Constantinople and Tehran and the Danube Commission, which had served before the war as lookout posts for the Eastern Mediterranean region, were henceforth to be managed by their respective governments, but France remained in charge of the Tangier office. The maritime and quarantine health council in Alexandria continued to be responsible for the medical supervision of pilgrims travelling to Mecca.

The League of Nations set up malaria and cancer commissions and dealt with matters such as nutrition and harmonizing pharmacopoeia. Since the fear of epidemics did not disappear, it worked at improving the medical regulations relating to sea transport, air transport, quarantine and the bills of health required for access to harbours, the eradication of rats from shipping vessels, etc. The League of Nations also cooperated with the recently created International Labour Office (ILO) on matters concerning the prevention of occupational accidents and disease. Both organizations had their headquarters in Geneva.

The Red Cross Societies had played an important role during the war, aiding both the armed forces and the civilian populations. The five Societies set up in the main Allied countries held a meeting at which it was decided to set up a permanent organization, the League of Red Cross Societies, also based in Geneva. In some countries, the Red Cross had a monopoly on blood transfusion, a practice that had undergone some technical improvements and was still being widely used after developing during the war. It continued to combat tuberculosis, cancer, and alcoholism and to work for the protection of children (Plate 76).

In addition to all these already long-established organizations, innumerable private associations were springing up, resulting in increasingly international contacts and exchanges of information and researchers. It would be impossible to list them all, but those that did the most for the health of the populations were no doubt those specialized in the study of tuberculosis (already underway for several decades) and cancer.

Two international health conferences organized in Paris in 1926 and 1938 by the governments involved led to some interesting comparisons on the state of health of the countries participating, but the atmosphere was not the same on both occasions. In 1926, the League of Nations was setting up its structures, but in 1938, political divergences made concrete achievements impossible. Although the 12-year interval between the two conferences was much shorter than that which had elapsed between similar events during the previous century, there was definitely a loss of interest due to the existence of permanent organizations such as the OIHP in Paris, the League of Nations in Geneva

and the Pan-American Organization in Washington. The secretariats of the organizations were able to draw up an approximate picture of the world health situation on their own, and their efficiency was ensured by the permanent participation of the governments.

## 1940–1950: A DIFFICULT PERIOD FOR THE WORLD

### The ailments of war

The League of Nations turned out to be incapable of carrying out the mission it had been set in 1919: to settle any dissension between nations, so as to prevent the situation from degenerating into war. The conflict triggered in Europe in 1939, after the preliminary rounds in Ethiopia and Spain, degenerated into global warfare in 1941. As always in the history of humanity, the war degraded the state of health of millions of people, and epidemics raged in many places. The most original feature of this war was that the losses incurred among non-combatant civilian populations were similar to those of the armed forces.

Once again, the movements of the troops and the shifting populations resulted in a typhus epidemic in Eastern Europe. This disease was endemic in the German prison camps, whose occupants were crowded together and undernourished and where the basic rules of hygiene were neglected.

Armies travelling around the globe were exposed to very different and unfamiliar climatic and environmental conditions, and many soldiers contracted malaria. The Australian units in Romania and the Balkans caught the disease, which was lethal in many cases. The Germans in Tripoli were less severely afflicted by it than the Americans on the Pacific Islands. In the Near East, the passage of troops between Asia and the North African and European battlefields, along with the relaxation of public health supervision, led to a cholera epidemic, which persisted in Egypt during the 1940s, even after the end of the war (Plate 77).

Rationing and food restrictions favoured the spread of tuberculosis. Those living in closed communities, such as camps, ghettos, psychiatric asylums, and other institutions, suffered from famine. The death rate among tubercular patients at sanatoriums was strikingly high. As usual, the main victims were young infants and the elderly. Among the civilian population and prison camp inmates, there was a recurrence of hormonal and vitamin deficiency diseases that had been eradicated in Europe for several decades such as nutritional oedema, rickets, and amenorrhoea.

Just as the First World War had ended in a huge influenza epidemic, the Second World War culminated in the proliferation of the poliomyelitis virus, although its victims were less numerous. These circumstances led to improved rehabilitation techniques and equipment (for treating functional respiratory deficits, for example), and the efficacious Salk (Plate 78) and Sabin vaccines were soon developed (Table 2). A sizeable epidemic of viral hepatitis also broke out.

In occupied Europe, the military health services and public health administrations were still working with pre-war techniques, whereas Anglo-Saxon industrialists and research scientists were constantly perfecting their therapeutic methods. This meant that their soldiers benefited quite early on from penicillin, which was invented before the war by A. Fleming and manufactured in the United States. The American and British medical specialists developed closed circuit anaesthesia, a whole range of surgical instruments, and methods of treating limb artery wounds and packing and transporting blood supplies for transfusion. The civilian population in Europe had to wait a few years before they were able to take advantage of these innovations.

The benefits of the industrial research and development carried out during this period were to be felt for several years. In response to the worldwide poliomyelitis epidemic, new emergency techniques, especially respiratory ones, and new types of orthopaedic aids and replacements were developed during the immediate post-war period. When biocompatible metallic and synthetic materials were made available, it became possible to implant vascular and articular endoprostheses.

The advent of peace led to the discovery that some quite unprecedented forms of human cruelty had been perpetrated in several of the countries involved in the war, where millions of people had died in concentration and extermination camps. Nazi and Japanese physicians had been performing surgical experiments on healthy people without any scientific justification and with mostly fatal results. These atrocities gave rise in international law to new concepts such as 'war crimes' and 'crimes against humanity'.

**Convalescence**

Governments everywhere, whether or not they had been involved in the war and whether or not they had been occupied by foreign powers, had taken various authoritarian measures during the conflict to safeguard their nations' health, and when peace was restored, they did not relinquish their efforts. However, a change of attitude had occurred since the pre-war period. The population's health was no longer thought of as the sum of all the individual inhabitants' health, for which each one was responsible; by now, it had become a matter for the state. To provide for the welfare of all, from both the medical and social points of view, was henceforth a state obligation and a citizen's right. On the other hand, the fact that the civilian populations had suffered as badly from bombing and deprivation as the members of the armed forces gave rise everywhere to a spirit of national solidarity favourable to the concept of collective health. Accordingly, the structures responsible for managing the health of the population were renovated at this time in many countries and gained a new lease of life. The reconstruction of ruined towns, equipment and collective establishments required firm administrative control, and the inhabitants of the Western world readily recognized a degree of authority they might not have tolerated one century earlier.

The British Government had drawn up a vast social security project during the war, which was almost completely implemented in peacetime and taken as a model by the governments of France and other countries. Nearly all health care services became available free of charge to all social and professional classes, and sick people were not to be allowed to go without treatment because they could not afford it. A legally binding pact of solidarity brought together rich and poor, sick and healthy, young and old.

Each country devised its own system of financial support, administration, and management for dealing with social protection. A single body dependent on the state was instituted in Britain; Belgium opted for multiple mutual societies; Germany updated the system of funding based on the sectors of activity, which had already acquired years of experience; and France kept the system based on membership of the trades and professions. These systems were financed in most cases by contributions deducted from the citizens' wages. The coverage offered by most of these organizations included sickness and maternity insurance, occupational safety and health insurance, and a retirement pension scheme.

None of these systems was provided right from the start with the funds necessary to cover the expenses of the whole population and protect all its members equally, or with a coherent administration or an irreproachable management. Readjustments were necessary everywhere and continued to be made up to the end of the century.

During the war, the Allies had also defined the founding principles of the United Nations, which was to replace the defunct League of Nations. This time, however, Roosevelt, unlike Wilson, who had not been supported by the American Congress, drew up the rules of his own personal United Nations, of which the United States was to take control. The word 'health' was slipped almost surreptitiously into the United Nations Charter, but it meant that the idea of a health organization was accepted at the 1945 San Francisco Conference, and the structure of the World Health Organization (WHO) was approved at the 1946 International Health Conference in New York.

WHO's headquarters was to be in Geneva, and its first managing director was a Canadian, Brock Chisholm. Regional offices were opened in several places during the next few years to facilitate the collection of information and to ensure that local conditions were taken into account: Copenhagen was chosen for Europe, Brazzaville for Africa, Alexandria for the Eastern Mediterranean region, Delhi for South-East Asia, Manila for the West Pacific, and Washington for the Americas.

The member states found the health conditions in the world so disturbing that the United Nations, not content with having created WHO, set up the International Children's Emergency Fund (UNICEF). The precarious state of health of the 'displaced persons' uprooted by the shifting European frontiers and of the prisoners of war released from concentration camps suggested that a health section should be set up within the United Nations Administration to deal with relief and rehabilitation (UNRRA). For similar reasons, the creation of the State of Israel gave rise to the need for aid to the displaced Palestinians to be organized (UNRWA).

During the war, the colonial powers had continued to pursue their efforts to promote health in the countries they occupied, but they were no longer able to meet all the requirements in terms of numbers of personnel, equipment, and financial support. They therefore applied for means to be made available locally. Qualified local doctors and administrators were trained and engaged who were to form the backbone of all these countries' health departments when they gained their independence.

## 1950–1978: A PERIOD OF ENTHUSIASM

The Second World War, which few countries in the world escaped, was followed by three decades with two distinctive features. On the one hand, the industrialized countries underwent a period of economic expansion, which led to the growth of towns and industrial potential. On the other hand, many nations which had been colonized gained independence. Events of these kinds might well be expected to lead to a magnificent improvement in people's health, and possibly also to the disappearance of some diseases.

This period ends in 1978 because it was during the summer of that year that the annual World Health Assembly organized by WHO sent the world a spectacular message, which was to inspire even greater hope and enthusiasm.

**Contagious diseases**

Penicillin began to be manufactured by chemical synthesis in many countries, and within a few years, it became available all over the world at little cost. This drug was soon accompanied by other substances belonging to the same family, and by other antibiotics (Plate 79). Since penicillin destroys the most common microbes, a whole class of suppurating lesions of various kinds were eliminated in hospitals, such as the pulmonary and pleural infections which had been so common in the past, and staphylococcal osteo-articular infections, which had had such devastating effects on children.

The systematic prescription of penicillin for streptococcal throat infections transformed scarlet fever into a benign disease. Not only did school epidemics of scarlet fever become a thing of the past, but the dreaded outbursts of acute rheumatic fever also became rare.

This sharp decrease in the incidence of the most common infectious diseases obviously occurred only in countries able to afford antibiotics, which are difficult to manufacture and therefore relatively expensive. During the Cold War, the Non-Aligned Countries were collectively denoted the 'Third World'. The immediately apparent differences between the financial resources of the above two groups of countries had health repercussions, which will be frequently referred to below.

Penicillin turned out to be an efficacious means of combating gonorrhoea, but its effectiveness against the syphilis bacterium *Treponema pallidum* was surprising, as these two infectious agents do not belong to the same family. Therapeutic approaches which had been in use for centuries suddenly became obsolete, and one of the branches of venereology was completely transformed. In particular, the dreadful neural and mental complications of syphilis were eliminated, and theories about the hereditary nature of syphilis had to be revised.

During the immediate post-war period, the use of another antibiotic produced on an industrial scale, streptomycin, spread rapidly among all the Western countries. Thanks to the prescription of streptomycin in association with other drugs, tuberculosis – whether its focus was pulmonary, osteo-articular, or meningeal – could now be quickly cured. Patients with tuberculosis needed to be admitted to hospital only during the infectious stage, and the treatment could then be continued in their own homes. The many establishments which had been opened in every country both between and immediately after the two world wars to deal with tuberculosis suddenly became redundant, and were either closed down or used for other purposes.

Publicity campaigns were launched to promote vaccination with the BCG vaccine. Some newly independent countries adopted it on a large scale. Tuberculosis can spread easily among people of all ages living in overcrowded conditions, which is often the case in country huts, *favelas* and shantytowns. This period was characterized by the uncontrolled growth of towns, along with all the medical, social and moral risks which accompany crowded housing conditions and a lack of proper regard for hygiene.

Although cholera and the plague were still endemic in some African and Asian countries, the world was no longer threatened by smallpox. Smallpox vaccination, which was easy to perform and inexpensive, was generalized. WHO, which had been responsible for promoting this procedure, predicted that smallpox would be completely wiped out for humans. It is certainly true that, since the last case was recorded in Somalia, nothing more has been heard of the disease. Convinced that there was no risk, WHO offered to pay a prize to anyone who could provide authentic proof of a new outbreak.

This was the first known case of a human epidemic disease that had disappeared thanks to human efforts (Table 3), but unfortunately, it has remained the only case so far. For a long time, researchers hoped to achieve equal success with poliomyelitis, but here the difficulties to be overcome were different. The disease is spread by viruses of several different types, the vaccines do not keep well, and unlike the smallpox virus, which is transmitted from person to person, the poliomyelitis viruses abound in freshwater everywhere.

During these years of high scientific hopes, malaria was expected to be stamped out like smallpox. Research in the chemical industry, which had been stimulated by the war, led to the development of DDT, a powerful insecticide. DDT was therefore lavishly applied in the many swampy areas throughout the world where the disease was endemic, with encouraging results. It soon turned out, however, that it did not suffice to eradicate the adult mosquitoes, and that the insects began acquiring resistance to DDT. After working so hard for three decades, people began to realize that it was not possible to interfere with ecosystems without causing some harm.

Other methods of fighting malaria were found to be possible, and they were all used simultaneously. In tropical countries, care was taken to eliminate even the smallest expanses of stagnant water in which anopheles larvae were liable to develop, and intensive public information campaigns were gradually organized. The larvae were again targeted by spreading a layer of oil on the surface of still waters whenever possible. Many efforts were made to drain and dry out marshlands.

By combining all these methods, progress was definitely made (Table 4). The northern and southern shores of the Mediterranean are by now devoid of malaria, as is the whole of Western Europe, whereas one century ago the disease was present in every country in the world. The last cases to be reported occurred in Greece in 1963. Nature has also lent a hand: in Scandinavian Lapland, there are far too many lakes for it to be possible to dry them out, and mosquitoes are widespread. Nonetheless, local populations no longer suffer from malaria, probably because the endogenous anopheles have been replaced by another variety, which does not carry the haematozoon responsible for transmitting malaria to humans.

Vaccines affording protection against two other contagious diseases, measles and German measles, also became available to the public. These are mainly childhood diseases, but when contracted by pregnant women, they can lead to embryonic malformations. Since measles vaccination has become a common practice, infantile bronchopneumonia no longer occurs as frequently as in the past.

Within a thirty-year period, the incidence of infectious diseases has thus completely changed among most of the world's inhabitants. It would not be fair, however, to attribute this improvement to medical progress alone. In both the towns and the countryside, housing conditions have improved with the expanding economy. In Europe, the water mains have been extended to rural communities, thereby ending their reliance on traditional wells, which could easily escape the health inspectors' notice and were often placed in the vicinity of animal droppings.

Urban housing built after the war was equipped with bathrooms and sanitation, and the annual per capita water consumption increased ten-fold in the newly built-up areas. The construction of modern apartment blocks, regardless of whether this was the cause or the outcome of social change, meant that the older buildings no longer tended to become overcrowded by several generations living together. The acquisition of washing machines (Plate 80) by most households made underwear more hygienic and abolished body parasites, while the use of refrigerators and dishwashers improved the level of food hygiene. Of course, these improvements did not immediately reach all layers of society, even in the industrialized countries, but they played an important role in that they served to prevent the transmission of common microbial disorders.

## Sickness insurance schemes

Health care, or at least some state contribution towards the cost of medical attention in the event of illness, seemed quite a realistic aim in the post-war period, since the nations were becoming prosperous. The generous projects nurtured by the governments at that time could now be put into practice. The principle was that medical care should be partly or entirely free of charge for as large a proportion of the population as possible. There were several possible ways of achieving this.

Britain adopted the type of state system used in the Soviet Union since the 1920s, which was subsequently copied in the socialist states created after 1945, as well as in Australia and some of the Canadian provinces. The state financed and managed all the medical structures required by the population, regardless of the illness involved and the type of care required. This all-embracing system looked quite satisfactory, since it abolished the inequalities due to a person's place of residence, income bracket, or walk of life. The idea of free medical care for all seemed most appealing.

*Table 4* **Malaria morbidity in selected countries**

*Stage of programme is the last quoted.

M = Maintenance phase; C = Consolidation phase; A = Attack phase.

† All cases reported in countries in maintenance phase were imported or induced.

*Source:* P. Yekutiel, 1980, *Eradication of Infectious Diseases: A Critical Study*, Basel, S. Karger, p. 71 (Reprinted with permission from S. Karger AG, Basel).

France, Spain and Germany, some Canadian provinces and Israel continued in the tradition established by Bismarck. Insurance funds set up by the various professional organizations managed the sums deducted for this purpose from the employees' wages. In the case of the first model cited above, the state acquired its resources from the tax system, and in the latter case, the special funds acted as insurance companies, with the risks involved in all insurance, but with some important differences: the subscriptions had to be paid up by the employers, and employees were mandatorily insured and could not choose the amount of their insurance contributions, which was set by the state.

In both cases, the feasibility of sickness insurance depended on the prosperity of the nation. In those countries where the coverage was initially restricted to only a few categories, it was gradually extended to others (such as craft workers and farm workers), and types of care and therapeutic methods not initially included were gradually covered. In any case, the number of employees was increasing at this period of full employment, and larger sums could be spent on health: old-fashioned hospitals were renovated, and establishments were equipped with the latest and most expensive equipment invented by medical technology.

Since the egalitarian spirit underlying sickness insurance meant that hospital expenses were also covered, members of all social classes chose to attend the public hospitals, which had previously been frequented only by the poor. Since establishments were sure to obtain financial support, they proliferated in order to satisfy the popular demand for easily accessible local medical facilities. As a result, the number of hospitals actually required was sometimes overestimated.

It would have been contrary to American tradition to set up a system of this kind, which in some respects might seem to resemble assistance based on a collective management system rather than insurance. The ideal of free enterprise and a rather puritanical conception of poverty as divine retribution prevented this type of insurance from being institutionalized in the United States on a national scale. The federal structure of the United States constituted a further barrier. The example of some Canadian provinces which, as early as 1947, had adopted various schemes, showed that the states could each adopt the mode of welfare that suited them, rich states tending to behave differently from poor ones, and industrial states differently from agricultural ones, for example. The large industrial firms that were forming at that time designed their own systems of insurance for their employees. One can imagine the extreme diversity in the cost of the insurance premiums, the amounts deducted from wages and the benefits accruing to the beneficiaries. There still existed social inequalities between whites and blacks, and the latest immigrants, mostly of Hispanic origin, enjoyed neither regular income nor social welfare. The federal government therefore took steps whereby it became mandatory for all the states to aid the elderly and the destitute. Medicare and Medicaid came to the rescue of millions of people.

This description of what has been achieved in the United States and the gaps that remain to be filled illustrates the difficulties faced by any system of health insurance, whether the country involved subscribes to a free trade or socialist system, and whether it is industrialized, developing, or semi-developed, as in the case of some European and Latin American countries.

The limited financial resources of the newly independent developing countries did not enable them to extend the benefits of health insurance to the whole nation, except for a few countries with a socialist economy, such as Cuba, and some African countries. The latter were attracted by the idea of free medical care for the whole nation. In other places, where prosperity was expected to arrive quite soon, some categories of employees were given social coverage immediately, and the number of beneficiaries was planned to increase gradually.

Foreign companies were obliged by the host countries to protect their employees by insuring them against occupational accidents and disease. The profits made by these companies were assumed to be such that they could afford to be generous. The state then followed suit by insuring its own army, police force, treasury staff, and eventually, members of the teaching profession. The country's own firms were then required to participate, since their employees were increasing in number.

The expansion of the hospital system in the more affluent countries was also taken by the poorer ones to be a sign of prestige. Some of them set up modern hospitals, which although not always adapted to the local customs or to the country's administrative and technical possibilities (how were they to ensure the maintenance of sophisticated equipment, for instance?), dispensed the latest in medical and surgical care.

The gradually expanding economy attracted underemployed inhabitants from the country to the towns. The capital cities of these countries soon housed one-third of the whole population, and this situation soon became the sign of a poor country. The new arrivals were often able to find only temporary, poorly paid employment, and the numbers inhabiting wretched, insalubrious quarters grew alarmingly.

The new health policies may have benefited city dwellers with steady jobs, but they did nothing for country folk, and despite the tendency towards urbanization, the developing countries were still predominantly rural. Rather than growing food crops, the rural population tended to produce cash crops or minerals for export, which made them particularly vulnerable because the price of these commodities was subject to the fluctuations of the world market.

### The structure of public health systems

The most obvious aspect of a public health system's activities, the provision of care, is of utmost importance to the public. Governments are also concerned with this issue, primarily for reasons related to political policy and prestige. In the Eastern European socialist countries and in countries where health insurance had been 'socialized', such as the United Kingdom and the Commonwealth countries, the state and the local authorities generally made all the decisions concerning matters such as where the sick inhabitants of a given area should preferentially (if not compulsorily) consult, how the members of the medical profession should be distributed and how much they should be paid, the location, equipment and management of hospitals, the production and distribution of pharmaceutical products. A reliable administrative structure was necessary to deal with all these aspects.

Those countries with free trade economies were not attracted by this type of highly simplified management, which in fact gave the government complete financial, geographical and technical control over health care provision. In the name of free enterprise, they ended up with a two-tiered health system. Governments first had to sustain and develop public health administration at both central and regional levels. The technicians engaged for this purpose had to supervise the application of health laws, the smooth running of the local health offices, the management of the regulated health professions, and the functioning of public health establishments, and to report any human or animal epidemics constituting a risk to public health, organize emergency aid in the event of catastrophes and inform the central authorities. A professional corps of this kind requires people with training in various relevant fields such as economists, managers, and members of the health professions and epidemiologists. Many countries set up schools of public health. These representatives of the central government working all over the national territory were invested at the local level with the authority and decision-making powers of the national officials themselves. These usually competent, devoted and poorly paid people were so attentive to the state of health of the populations they were dealing with that they contributed greatly to improving the health of the world.

Alongside this public health network, private health practitioners and establishments were also developing. Although they were subject to administrative control, they and their clientele enjoyed several kinds of freedom: the freedom to set themselves up wherever they chose, to prescribe whatever treatment seemed most appropriate, to set their own fees, as long as these were compatible with the patients' private insurance schemes, and freedom for the patients to choose the physicians they consulted and the place of consultation. In this way, two sets of requirements were satisfied: on the one hand, the public health organization was there to look after the well-being of the community and to protect it from various health risks, and on the other hand, there were the free practitioners of medicine who did not need to worry about collective health issues, but were able to concentrate (quite rightly) on restoring the health of the individual patient.

In the poor countries, this dual system led to striking discrepancies. While public health structures were rather flimsy and lacked resources in terms of both staff and funding, physicians trained in Western methods opened private practices in the cities, leaving the countryside to fend for itself. These physicians earned a good living by treating patients with steady jobs, who were therefore insured. Thus, inequalities among those in need of treatment became gradually more marked.

Prevention, in comparison with these health care systems, had less visible effects, since the accidents and diseases effectively avoided and the costs thus economized are more difficult to demonstrate statistically. How can one show the importance of events that never occurred? Prevention is therefore of less value politically, since it is less spectacular than curing diseases and building fine hospitals. And yet few nations have failed to avail themselves of the advantages of preventive medicine, as the following few examples are intended to show.

The increasing use of vaccination has already been mentioned above. In most advanced countries, occupational medicine, which aims to prevent occupational accidents and disease by having all those in employment systematically examined, has been widely adopted. Preventive medical departments almost everywhere were operated at the expense of employers, who attempted to limit their scope, and thus to save money. In theory, company doctors were paid to ensure that wage earners were suitable for the positions they occupied. They were not allowed to go any further, however, or to give the persons they were dealing with an overall check-up.

The same could be said of the medical departments in charge of supervising the health of young people attending schools and universities. Even in the most advanced countries, these departments were understaffed and underequipped, their scope was too restricted, and they were badly paid. Sports medical departments, responsible for checking whether a person was fit for a particular type of sport or the competitive event, were generally more efficient because they were financed by athletes' voluntary contributions and by sporting associations.

Countries with complex administrative systems had plenty of opportunities for promoting preventive medicine. The quality of the home-grown and imported agricultural products available on the market needed to be controlled to ensure that they were safe to eat. Customs authorities had to check that articles manufactured in other countries were risk-free, including domestic and industrial equipment, toys, clothes, and fabric and building materials. The health of immigrants crossing the borders was sometimes checked to prevent contagious diseases from being introduced. Even the chemical composition of beverages manufactured at home and abroad had to be tested.

The damage done to health by uncontrolled urban expansion is well known. Only a few countries have managed to control the living conditions of the new arrivals in large cities by building special accommodation in advance on sites already provided with amenities such as roads, running water and sewage systems. This rather authoritarian method of preventive medicine was not compatible with all national cultures, however, nor could all countries afford it.

Although consumers were not always aware of it, every article they were using had been checked by the public authorities to protect them from innumerable risks. It is not possible to estimate the resulting health benefits, since only the cost of running these departments can be calculated.

Intensive hygiene campaigns were launched, using various media, depending on the cultural background of the country involved. The wording of a message and the objectives declared can produce different reactions in different places. The approaches varied (school lessons, slogans, the media, films, cartoon strips, etc.), but the themes were usually the same everywhere: teaching the appropriate procedures and the precautions to be taken when handling kitchen utensils, heating equipment and tool kits to avoid domestic accidents (these are responsible for more serious accidents than are caused by transport), informing people about the effects of alcohol on drivers of motor vehicles, how to observe the rules of hygiene in everyday life, what a balanced diet should consist of, and precautions to be taken when engaging in sexual intercourse.

As far as preventing smoking and drinking is concerned, however, no government in the world has solved the contradictions involved in educating their citizens. Although

the toxic effects of tobacco and alcohol have been clearly established for a long time, they are a source of profit to the state. Most of the countries that gained independence during this period either set up state monopolies on these products or taxed them heavily, which did not prevent their consumption from increasing everywhere. Since fashions are often imitated, recently independent poor countries tended to copy the behaviour of the wealthy countries, even when it came to their bad habits. Since they are incapable of making more reasonable decisions, states still prefer to incur the expense of caring for those who have been intoxicating themselves for years, rather than to reduce their immediate revenue by taking measures to prevent the damage. None of the states is in the least ashamed of playing the role of drug dealer.

Birth control was a highly controversial public health issue during the period under study here. Family planning set up factions within religious circles, opposing strict adherents to those with a more pragmatic outlook. Once some of the poorer countries that had succeeded in increasing their national revenue thanks to the efforts of agriculture, industry and commerce realized that the profits were dwindling because of the high birth rate, they decided to take measures to bring it down. In other countries, numbers were thought of as being the only real source of wealth for the people. In many cultures, the degree of pride a father and a mother are entitled to feel depends on the number of children they produce. This issue is also related to the role of women in a civilization: are they destined to be forever the inferior sex, or are they allowed to control their own bodies and their own fertility? Birth control therefore raises medical, social, cultural, religious, economic and other questions (Plate 81).

For the first time in the history of humanity, birth control was discussed openly throughout the world owing to two completely new methods of contraception: oral female contraception, which requires some self-discipline and is relatively expensive; and intra-uterine devices, which have to be installed by an experienced specialist. Both methods require regular medical supervision, and their cost made them unsuitable for large-scale use in the underprivileged countries, where they were the most urgently needed.

It is therefore easy to understand why governments aware of the risks associated with overpopulation have sometimes taken authoritarian measures, for example in China, where fertile couples were fined, or lost their jobs or homes. Although the full impact of these measures cannot be assessed yet, the national pattern of demographic growth certainly slowed down as a result.

In India, the male members of the population were targeted, since men can easily be sterilized by performing a brief surgical intervention requiring only local anaesthesia. Information campaigns were run in which cash bonuses were offered as an incitement, but had to be stopped because of public protest. Several thousands of men were sterilized, but in a country with a population of more than 950 million individuals, these effects were barely perceptible.

The consequences of birth control were quite limited in fact during this period, even in the most needy and overpopulated countries: too many interests were at stake, and the opinions voiced about birth control were too contradictory to have led to anything but very short-term policies.

The governments of most countries, however highly developed, paid growing attention to their public health systems because of the economic implications and the interest shown by the electorate in health systems and in the savings they entailed. Health systems were never given top priority, however, and ministers of health were never granted complete freedom of decision, but their proposals were always considered on the basis of cost and not in terms of their value to the nation's health. Throughout the world, preventive medicine and the quality of health care were seldom judged from the point of view of the benefits to the community, and health always came second to economic considerations.

In view of the demands of the public and those of the medical profession for hospitals to be built everywhere, all equipped with expensive materials (e.g., scanners), some efforts were made to introduce some rational thinking. Thus a new concept of public health planning emerged: from then on, everything had to be planned in advance – the distribution of doctors and hospitals within the country, the acquisition of sophisticated and expensive equipment, the renovation of out-dated hospitals, the amortization of radiological diagnostic and therapeutic equipment, and the transition to computer processing in the management of health insurance funds. The 'Planning-programming-budgeting system' (PPBS) in vogue in business management in the 1960s was also applied in the field of health administration. A fine example of its application in France is provided by the decision on where the maternity homes should be located. There was a choice between either having a large number of small maternity homes so that pregnant women would easily find one in the vicinity, or making exact calculations so that there would be a smaller number of maternity hospitals, permanently staffed and equipped with the latest and safest obstetrical devices. Taking the budgetary constraints into account, several measures were taken simultaneously that led to a conspicuous decrease in the morbidity and mortality of newborn infants and their mothers in France.

Public health planning required new ways of looking at medical issues, led to the training of statisticians, epidemiologists and medical computer technicians, and introduced into the field of medicine the idea of looking at large numbers. This was a real innovation, since medicine for thousands of years had always focused on finding the solution to individual problems. Those who were too naive or enthusiastic about planning at the start were also obliged to recognize its limitations. Public health problems are not all reducible to quantifiable data, and there is necessarily some degree of uncertainty. Lastly, plans were often made for a five-year period, during which everything is liable to change, namely, the wishes and needs to be satisfied, the medical techniques available, the political context, etc. All these changes might make it necessary to modify the initial plan. Experience soon taught the new public health managers that plans are necessary but that they are seldom actually carried out as expected.

These efforts at planning also revealed how intricately health phenomena were bound up with social ones. Over the centuries, the distinction had developed between the medical profession with its long-standing history, its techniques, and its scientifically based view of the world, and social workers with their closer experience of human situations and behaviour and the training in uncertainty

they had acquired in studying the relatively new discipline of sociology. Efforts were made to have the two professions work hand in hand in the context of 'community medicine'.

The idea here was to bring together the social and medical approaches to a population, so that the problems encountered by groups and by individuals would be systematically approached from both points of view. University chairs and institutes of community medicine were created all over the world. This concept was particularly popular in Quebec; and in specially created local community service centres (known locally as CLSCs), the public could find all the necessary services and professionals under one roof: experienced social workers, medical dispensaries of several kinds, outpatient consultations, and practical and administrative advice about all aspects of everyday life.

This was a good idea that was successfully applied in a number of developing countries. The older European nations were too set in their traditional ways to show much enthusiasm for this new concept. They preferred to be treated by their familiar family doctor, who was progressively given a more dynamic role to play.

After the war, the United Nations created WHO specifically for the purpose of dealing with the world's health problems, with particular emphasis on improving the poor state of health care in the former colonies (Plate 82). Not only were these new countries short of the resources and qualified staff needed to run an efficient administration, but they were also riddled with food shortages, poorly balanced diets, vitamin deficiencies, and uncontrollable parasitoses.

The efforts made by industrialized countries to aid the developing ones increased constantly between 1950 and the late 1970s. The wealthy countries stepped up their bilateral aid programmes. As WHO was not able to cope on its own, numerous other bodies had to step in for various reasons. In the field, special missions dealt with specific diseases such as malaria, river blindness, and bilharzia, to mention only a few. Administrators helped to set up the structures necessary for projects to be properly planned, and managers made sure that funds were put to good use. Aid gradually began to be provided by organizations such as the United Nations Development Programme (UNDP), the World Bank, the International Bank for Reconstruction and Development (IBRD), the Food and Agriculture Organization (FAO), which gave these countries new seeds for their crops and improved their agricultural techniques, UNICEF, and the United Nations Population Fund (UNFPA), to mention only the most well known. The activities of these numerous organizations overlapped, causing a certain degree of waste, but the specific nature of each one made it impossible to organize mergers between them: the poor profited from the disorder sown by the rich, and in their diversity, all forms of aid provided were beneficial to the health of the local populations in the long run.

The most active organization in the field, however, was always WHO. In the course of time, its structures and the number of member states changed. Some countries switched from the regional office to which they were initially affiliated to another. Tunisia, after being assigned to the European office, joined the Eastern Mediterranean one. Israel also associated itself with Europe as soon as it became a member of the United Nations. The USSR, along with a few other Soviet Republics, briefly left the organization and subsequently returned. Heated debate occurred between the People's Republic of China and the Taiwan authorities

as to who was to represent China, and a similar situation arose between the opposing governments in Cambodia. The Cold War between the communists in the East and the free-trade economists in the West encouraged both camps to acquire a clientele among the newly independent countries.

WHO was financed, like most of the other United Nations organizations, by the contributions of its member states, which were proportional to their wealth. It managed to draw further resources from special funds set up for specific public health purposes, such as controlling parasitoses or helping the victims of natural disasters in a given country or part of the world, which were voluntarily financed by some states. This initiative was not appreciated by all, since the reputedly rich countries were not all equally rich, and also because the former colonizers, for economic and linguistic reasons, had maintained their influence in some regions and wanted to continue doing so. Worldwide public health cannot be attended to without coming up against political rivalries.

For similar reasons, the scientific thinking of those in charge of WHO was not to the liking of all its members. For example, they quite justifiably attempted to explain to member states that organizing preventive medicine would have broader and more long-term effects than simply curing a list of diseases. WHO created a special terminology in this context, which the medical profession had difficulty understanding. For example, 'primary prevention' included vaccination and the destruction of vermin (such as rats and mosquitoes), which seems quite logical. The systematic screening of diseases such as cancer or high blood pressure at such an early stage that no symptoms had yet appeared was designated, however, 'secondary prevention', although this was surely no longer prevention, since the disease had already been developed in some cases. Lastly, the term 'tertiary prevention' was used for treating diseases appropriately in order to 'prevent' the after-effects, but it was not very clear how this form of prevention differed from therapy. WHO, which brought together almost 200 nations speaking nearly as many languages, working on scientific topics in certain cases not yet completely elucidated, sometimes encountered difficult linguistic and terminological problems in the course of its activities.

Be that as it may, WHO has made a unique contribution to the health of nations. It took over successfully from its predecessors in the battle against contagious disease, drew up international health regulations, and collected epidemiological information from all over the world. To make descriptions of disease more accurate, the organization drew up and revised an international system of classification of diseases. It founded a universally recognized pharmacopoeia. In its efforts to improve the nourishment of underfed children, it succeeded in regulating sales of artificial milk. WHO also launched numerous field missions and trained local people in several medical professions in countries where no vocational training structures were yet available.

International public health cooperation did not consist merely of the assistance granted to the poor by the rich. No doubt because the two world wars had provided dramatic examples of deadly conflicts that might have been avoided, some countries made noteworthy efforts from 1950 onwards to collaborate by pooling their common economic, scientific, political and cultural interests. The increase in

international communications and trading and the relaxation of cross-frontier restrictions facilitated the conclusion of new alliances between nations, depending on their geographical situation.

Europe set the main example with its numerous institutions created for various purposes, but similar trends could be observed in other regions, such as North and South America, the Arab countries, and South-East Asia. In Africa, especially the French-speaking parts, the former colonies benefited from the assistance of the pre-existing colonial health departments in the war on endemic disease, and the central African countries set up their own coordinating structures. In Europe, the European Union (formerly known as the European Community) was set up for purely economic reasons. But the Council of Europe, which had a larger membership than the Union, has created a Health Committee to deal with health-related issues. It carries out investigations and reports findings, which are not subject to the approval or the vote of all the member states, some of which can express qualified support by signing partial agreements. Among the points dealt with in this framework, we should note the European agreement concerning blood transfusions and the exchange and sale of blood supplies among Union member states.

It is not possible in the present article to examine in detail the strides made in medicine during this period, mainly thanks to progress in biochemistry, the study of living organisms and the changes they undergo in the event of disease. The discovery of deoxyribonucleic acid (DNA), an essential component of living tissues that transmits genetically inherited characteristics, was of decisive importance in the field of life sciences. We will briefly mention only a few of the innovations that improved public health.

The progress achieved in the field of infectious disease, thanks to the intensive use of preventive programmes and the increasing number of antibiotics available, has already been mentioned. The unfortunate arrival of thalidomide on the antibiotics market illustrates the difficulties associated with a universal pharmacopoeia. Since none of the international authorities is capable of guaranteeing that a diagnostic, preventive or therapeutic pharmaceutical substance is both harmless and efficacious, each country is free to authorize or prohibit the marketing of a drug within its territory. A scientific consensus has been reached over the last three decades, however, as to what tests a medicinal product should pass before it is allowed to be marketed. Its effects on the organism must be tolerated by human beings, according to its composition and the results of experiments on several animal species, healthy humans and patients with specific diseases. Most countries have agreed to adopt standard test procedures along these lines. After satisfying these tests, thalidomide was duly authorized and distributed in several Western countries, where it was used to treat pregnant women with complaints of certain kinds. In 1959, however, it was observed in Germany and Australia that women who had been given this treatment were giving birth to children with limb malformations, and the existence of a causal link was definitely confirmed in 1961. The sale of this drug was henceforth prohibited. A few years later, however, the same medicinal product turned out to be a useful means of treating non-pregnant women and men suffering from leprosy, a disease on which thalidomide had not even been tested. This devastating accident underlines the scientific uncertainty surrounding any innovation and public health

decision. Acting in favour of one group of humans may be detrimental to another group, and destroying a living species that is harmful to humanity may have detrimental effects on other more useful species.

Millions of people all over the world suffer from metabolic and nutritional anomalies, which can lead to various types of cardiovascular disease. In this context, epidemiological surveys have been carried out for several years on specific populations in the United States and Finland. The results have shown that many people have neglected their high blood pressure, thereby exposing themselves to vascular brain damage, vascular occlusion (infarct) in the brain or other organs.

The results of these and other studies have attracted attention to the harmful effects of a dietary imbalance between the lipids, carbohydrates, and proteins ingested. In the past, the knowledge available in this field focused mainly on malnutrition of weaning infants in underdeveloped countries, and on some particularly well-documented deficiencies, but after these decades of prosperity, the pitfalls of over-rich diets began to become apparent. Excessively high cholesterol levels in the blood or other body fluids can cause cardiovascular diseases that can be prevented by keeping to more reasonably balanced diets.

Without wanting to draw an exaggerated picture of the contrast between over-fed industrialized countries and under-nourished developing countries, it should nevertheless be emphasized that this contrast does exist. To be obsessed with cholesterol has become fashionable, but millions of people have actually improved their health by applying simple preventive measures and adopting more sensible eating habits. Compare this with the cost of the spectacular cardiovascular and brain surgery carried out at magnificently equipped hospital centres, or with the heart transplants now possible thanks to the discovery of HLA tissue groups, which render grafted organs compatible with the host organism. All these achievements have saved the lives of only a few thousand patients, at great expense.

Similarly, the lives of people with chronic diseases such as diabetes have been improved. The distinction has been made between those with congenital sugar assimilation deficits, who have to endure regular insulin injections all their lives, and those with less serious and less permanent forms of diabetes, for whom an appropriate diet and drugs such as sulfamides can be prescribed. Diabetics, who number several tens of thousands, are thus spared the usual complications, lead normal lives, and live longer than they did previously.

The considerable progress made in the field of electronics has provided medicine with some useful tools. Ultrasound recording methods are used to explore the various ducts and organs, and to examine embryos and fetuses with a view to detecting any anatomical anomalies and predicting any obstetrical problems liable to arise. Ultrasound scanning is a painless, inexpensive means of exploring the human body with no ionizing effects. In many cases, it has replaced X-ray methods. Although this method requires highly trained staff to interpret the results, it is appreciated in many poor countries. However, an international survey carried out by WHO showed that a great deal of expensive radiological equipment lay idle in these countries because of mechanical failures that could have been quite easily repaired.

Research on biochemical and cellular mechanisms made possible the prenatal diagnosis of chromosomal anomalies

(affecting either the shape or the number of chromosomes, as in the case of trisomy 21, otherwise known as Down's syndrome or mongolism), functional anomalies (such as pancreatic fibrosis, also known as mucoviscidosis), and blood anomalies (such as haemoglobin problems). Methods of *in utero* investigation, along with the tests carried out at birth, have made it possible to apply corrective treatment at a very early age, and they sometimes lead to termination of pregnancy.

The increasing use of multidisciplinary approaches to disease has resulted in traditional ideas about the causes of disease being completely revised. In East Africa, for example, epidemiologists discovered that the incidence of a mandibular tumour was particularly high. Subsequent studies showed that several factors were responsible for the occurrence of this malignant growth: it only occurred when a specific virus (the Epstein-Barr virus) was caught by a patient with malaria suffering from malnutrition.

Many illnesses seem in fact to result from a combination of several factors. The recognition of interconnected causes certainly revolutionized the simplistic type of reasoning based on bacteriological models, according to which one cause leads to one result and one germ to one disease. These three decades of progress in most of the branches of medicine have shown living organisms to be increasingly complex in both their healthy and diseased states. Increasing the number of biological investigations was hardly the best way to solve many problems, and in certain cases it actually delayed the discovery of proper solutions.

Another new medical discovery was the fact that the pathological problems are intertwined with the moral, religious, cultural and economic particularities of each society. The more heterogeneous human groups become, the more difficult these problems are to solve. For this reason, 'ethics committees' (where the term 'ethics' has for some reason been substituted for 'moral') have been set up in hospitals and universities, sometimes on a national scale. The innumerable topics they deal with have sometimes required creating new legislation; however, the slowness with which this is achieved underscores the great difficulties involved.

## 1978: 'GOOD HEALTH FOR ALL BY THE YEAR 2000'

In 1978, the World Health Assembly, which was attended by nearly five hundred participants, launched this slogan, like a battle cry in the war on disease, which was to be the programme for the next two decades. This event took place in Alma-Ata, the capital of Kazakhstan in the Soviet Union. To many, this laudable aim announced on the dais in biblical, melodramatic tones by the Director-General of WHO appeared to be wishful thinking or an incantation against death, since to overcome disease is to abolish death. Those who were more sceptical or cautious might have preferred the statement 'Health care for all by the year 2000', which would have been a less ambitious, but still difficult, goal.

The Alma-Ata Declaration, which naturally obtained the unanimous approval of all the participants, was designed to cause a psychological shock among the heads of the member states by forcing them to take a critical look at their public health systems and the policies adopted over the previous decades. The implied criticism had to do mainly with the way in which 'primary health care' was organized throughout the world, i.e., the care dispensed to patients by members of the medical profession, or possibly by the most appropriate substitutes available, if there were any such within reach. The Alma-Ata slogan was therefore aimed primarily at the developing countries, but the advanced nations were rather puzzled about the meaning of 'primary health care', which was part of the WHO jargon. These countries had not waited for Alma-Ata before giving some thought to their health policies. They had provided those in poor health with a sufficiently large number of physicians (if not with more than were required), and anybody in need of care could simply call in the doctor or go to a hospital. Primary health care was therefore being well attended to, and so they wondered what 'secondary health care' might mean.

It was generally agreed, however, that the criticism of Third World health policies was justified. Since the underdeveloped countries lacked both resources and authority, all they could do was to follow the public health and administrative principles they had inherited from their former colonizers: in other words, to imitate the affluent countries. Physicians trained in Western methods were in short supply, and were established in the towns. Expensive new hospitals able to perform heart surgery had been built. Meanwhile, no provision had been made for those living in the bush and in the mountains, and the villages were suffering from food shortages and lack of sanitation. There was a growing need for all countries, especially the least privileged, to develop a new system of vocational training in public health, catering for all population groups. The idea of training health officers who were not necessarily qualified doctors was put forward. Training a lower category of staff with a good basic education to teach the basic principles of hygiene in the villages might be better than an inevitably poor level of medical care.

WHO emphasized the need to make better use of village storytellers and 'witch doctors' to train experts in the field – rather than calling on highly trained physicians unfamiliar with the public health background in their country – to increase the numbers of nurses and midwives, and to dispense elementary instruction to volunteers and village chiefs on how to filter river and marsh water and how to build latrines.

The Alma-Ata Declaration was therefore a call to the representatives of both rich and poor countries to question their own consciences and to revise their policies on a worldwide scale. Since so many nations were prospering, the state of health of all humankind really could be improved if all concerned decided to commit themselves to making every possible effort.

In 1978, it was indeed possible to be optimistic about the three decades ahead, as far as the health of humanity was concerned. The main causes of epidemics had been stamped out. The mechanization of production processes had turned factories into less dangerous workplaces. Agriculture had become more productive, making famines less frequent and less disastrous. The members of the medical profession were so clever that they were always achieving better results, and there was no reason to imagine that this would not continue to be the case.

Some countries that gained independence after the war were beginning to launch on the world market products

they would never have been thought capable of manufacturing, which enriched them to such an extent that the economic gap between the wealthy countries in the Northern hemisphere and the poorer Southern countries seemed destined to decrease. Life expectancy was increasing, infant mortality was decreasing, and the population was growing even in the most deserted, destitute corners of the globe.

Of course, many people realized that the Alma-Ata Declaration would not bring about the hoped-for health revolution, but everything seemed to indicate that human beings were progressing towards a more healthy life involving less suffering, since the state of economic prosperity was expected to persist.

## 1978–1997: A PERIOD OF DISAPPOINTMENT

The outcome of the Alma-Ata resolutions was not as successful as expected for several reasons. The industrialized Northern countries felt that these proposals, reasonable as they were, once again made calls on their generosity, and the developing Southern countries did not make all the efforts necessary for the appropriate changes to be made. The difficulties encountered on all sides were exacerbated by the fact that economic expansion was slowing down considerably, resulting in cuts in national budgets. During such crises, health expenditure is always curbed. Never before in the course of history had the health of humanity been so inexorably subjected to the power of money. Moreover, some diseases unexpectedly appeared or reappeared, calling for new public health measures and occupying a growing place on the epidemiological map of the world. The enthusiasm of the previous decades therefore gave way to disappointment, although the earlier achievements were not really seriously threatened.

### Infections and parasitoses

Once the international organizations had been properly set up and statistical methods developed, fairly reliable, worldwide epidemiological data were becoming available. These, however, were only the sum of the individual national data, and the degree of accuracy of the figures reported by the various countries varied in consistency. Quality was improving, however, and the classifications published were increasingly recognized and used, so that a more accurate picture of disease in the world was beginning to emerge.

It was observed that diseases were showing a greater tendency to spread internationally, owing to the increased amount of trading and travelling worldwide. Diseases do not tend to become identical when spreading from one place to another, however, since, although germs ignore borders, the modes of human contagion vary from one culture to another, and the insects which carry some diseases do not adapt to all climates and ecosystems. For the same reasons, it seems unlikely that the level of health of the world's entire population will ever be completely uniform.

It is not within the scope of this article to draw up a list of the main diseases threatening humanity during the period under consideration. All that can be done here is briefly to outline the main successes, the lesser successes

and the failures (which, it is hoped, will prove to be only temporary).

The successful battle against the epidemics of the previous century continued. Smallpox never reappeared. Yellow fever attempted to do so once in West Africa but was vanquished. Cholera was still endemic in Asia, and after crossing the Pacific, resurfaced in Peru and Brazil before crossing over to West Africa and finally disappearing altogether. The plague, which was still endemic in Asia, occurred only in a few East African foci.

New hope sprang up in the fight against leprosy, which in 1995 affected one million people in South-East Asia, especially India. A promising new drug, dapsone, was being used, and because *Mycobacterium leprae*, like the former smallpox virus, affects only humans, researchers hoped to eradicate it in the same way. The solution in the most serious cases turned out to consist of prescribing a combination of chemical drugs, and total victory may now be within reach.

Despite all the efforts made throughout the world, two dreadful diseases still exist, the first of which is malaria. This is still the main cause of death in the world, especially among children. The use of DDT to destroy mosquitoes had been prohibited in many places, and the *Plasmodium* species, which are most resistant to antimalarial drugs, seemed to be proliferating at the expense of the more sensitive species. Early in 1980, a deadly epidemic broke out in Madagascar. In terms of the number of deaths it causes every year, malaria remains humanity's greatest epidemiological challenge.

The war on tuberculosis has also come to a standstill. Although it was extremely successful in the industrialized countries throughout the twentieth century, too many small pockets of resistance still exist. In every country, there are still places where needy people live in overcrowded homes and quarters with no sanitation, contaminating one another and forming centres of infection; and the situation is sometimes exacerbated by AIDS. For various immunological reasons, the BCG vaccination campaigns have slowed down in Africa and India.

Even the fight against infectious agents, which are amenable to vaccination (meningococci, measles) has slackened: vaccines are expensive, and their widespread use requires the existence of roads and means of conservation and transport not available everywhere. The causes of diarrhoea, which can be so deadly to children, are various and include malnutrition, poor hygiene and epidemics.

The disappointment felt as we reached the end of the century is mainly due to the fact that humankind is still relatively powerless in the face of pathogenic viruses. The great medical victories of the past were won against microbes by means of appropriate drugs, whereas viruses are naturally unstable organisms: the influenza viruses mutate, for example, from one flu epidemic to another.

The most spectacular event in recent times has been the invasion of the human immunodeficiency virus (the HIV virus responsible for AIDS) (Plate 83). After being first suspected in the early 1980s and then identified in 1985, this virus spread throughout the world via two pathways, blood and sexual transmission. It caused considerable mortality during the first decade of its existence, but HIV-positive patients are surviving longer every year thanks to new therapies. The African continent has been the hardest hit.

Thanks to the improved laboratory methods of identification, viruses can now be more accurately detected and classified. The most formidable are the hepatitis B

and C viruses responsible for severe cirrhosis and hepatocarcinomas. An increase has also been observed in the incidence of sexually transmitted diseases. Although penicillin almost eradicated syphilis and gonorrhoea, at least in the more advanced countries, viral infections such as herpes, condyloma and papilloma have by now become quite commonplace.

One of the latest threats to human health involves even more elementary living particles than viruses, namely prions. After being named in 1982, they were identified in bovines, where they are responsible for the fatal bovine spongiform encephalitis (BSE) known as mad cow disease. The exact mode of transmission at work in cattle is not yet known, nor do we know to what extent this disease can be transmitted to other species, including humans.

Since worrying comes naturally to human beings, they hope past victories will continue to be valid forever, but, actually, this is no longer certain. Most of the viral diseases occurring nowadays existed previously but had not been properly identified, and their present-day occurrence has generated a wave of panic, especially as it is impossible to control them because too little is known about their composition and means of transmission.

### The cost of health care

Research on the diagnosis and treatment of these diseases is extremely expensive and has added to the cost of health care. Moreover, it is worth noting that, for political and demagogic reasons, governments are more willing to invest heavily in research on new diseases than on older ones.

For several reasons, countries everywhere are spending more on health. Diagnostic tests are made with sophisticated electronic, magnetic and computer-controlled equipment; drug therapy requires years of research and development; and surgical procedures are becoming more ambitious and precisely controlled. Children are treated at increasingly early ages, and growing numbers of elderly people suffer from several ailments simultaneously requiring a correspondingly large number of treatments, all of which incur costs. Provision was not made for financing such additional expenditures when the health insurance systems were instituted.

Social welfare of all kinds has reached a dead end. State-run health insurance systems seem to be resisting inflation with recommendable efficiency, if one compares their morbidity and mortality rates with those of other countries, but the strictly regulated way in which health care is dispensed in those countries with such systems would not be found acceptable elsewhere and meets with a degree of dissatisfaction even among their own inhabitants.

Industrial countries' health insurance systems, financed by subscriptions or wage deductions, have swollen the costs of industrial production (owing to the inevitable repeated increases in insurance premiums) and have thus led to a drop in consumption. To compensate for this process, public funds have had to be deployed.

In the United States, where, as we have seen, other options were chosen after the Second World War, a spirit of solidarity was created between the medical professions, health administrators and potential patients who share vested interests in health maintenance organizations (HMOs). It is in the interests of both health care providers and consumers that the best possible care should be dispensed at the lowest possible cost. The risks covered have been strictly defined, however, and the most expensive ailments have been ruled out. The federal government has been attempting to reduce the cost of health via Medicare and Medicaid, as described above. In the long run, however, the number of people with no medical coverage is on the increase, while those who are insured must pay increasingly expensive premiums.

The developing countries are even less in a position to extend health insurance to further categories of people. The ideals adopted by the governments in 1945, i.e., extending health insurance coverage to the whole population and providing everybody with the same coverage free of charge, are now beyond their reach. Those countries where these goals were almost achieved have had to take a few cautious steps backwards, calling on the civic loyalty of the members of the public who, after years of large-scale state assistance, had come to believe that the rights to which they were entitled were limitless. They have been asking the members of the medical professions, who prescribe too many treatments, tests and superfluous drugs regardless of cost, to take a more responsible attitude.

Every country has had to look for solutions that are both the least risky, politically speaking, and the most likely to maintain the nation's health at its present level. It seems probable that, in the present context, the proportion of the total national budgets devoted to public health will continue to decrease, although the actual amounts spent increase. The causal links between economic prosperity, public expenditure on health, and the state of health of the population are still rather unclear.

It can certainly be said that in terms of the morbidity and mortality and the life expectancy of the population at birth, the wealthy countries are in good health, and good health depends on economic development. On the other hand, one can hardly expect unhealthy people in poor countries to make strenuous efforts to step up productivity, although favourable health statistics do exist in the case of some countries and regions with low incomes and a small population, such as Cuba, Sri Lanka, Costa Rica, and Kerala (India).

### Industry and health

The industrialization of modern societies was bound to affect people's health, for two reasons: first, the equipment necessary for dispensing health care is manufactured industrially, and second, access to certain types of instruments tends to become the prerogative of consortiums, although the efficiency and the quality of the health care to which these two processes led have not yet actually been proved. It became apparent in recent decades that some industries can actually be harmful to the population's health.

Industrial mergers began to occur in the health industry during the 1970s because the first scanners were so expensive to produce. (Even the firm that invented the procedure went out of business.) The situation worsened when the early models were updated, radiological equipment was automated, magnetic methods were introduced for abolishing kidney and gall bladder stones, automatic

analysers were developed for making biochemical diagnoses, and ultrasound recording, magnetic resonance imagery and ionizing radiation equipment became available for diagnostic and therapeutic purposes. Such innovations were consistent with medical progress, but owing to their increasing cost and the limited scope of the market, industrial firms were forced to merge and combine their production and marketing activities. By the end of the century, there were only about half a dozen companies selling expensive equipment of this kind, which means that in some countries, they have monopolized the market and industrialists are able to exert pressure on the medical profession.

A similar process has occurred in the case of the pharmaceutical industry, which expanded rapidly during the late twentieth century. The cost of research and development is certainly on the increase, for it takes at least ten years and a great deal of money for a promising new molecule to be launched on the market.

The pooling of industrial activities has had various effects. The increasing production costs have led to higher sale prices, and whenever a new truly efficacious substance comes on the market, there is much heated debate between manufacturers and governments, which are interested in buying it, but have to consider public opinion. It is therefore hardly surprising that states would prefer physicians prescribe generic drugs, which have become common property when the initial patents expired.

In addition, manufacturers are free to choose their own fields of research. There is little advantage to be gained, for example, from supplying Southern countries incapable of paying their bills with drugs designed to treat purely local diseases such as parasitoses, for which there is no demand elsewhere. And why should they bother trying to treat diseases occurring only rarely in wealthy countries, since the low demand would mean that the research investment would take too long to pay off? These two examples of 'orphan drugs' (although it would be more appropriate to speak of 'orphan diseases', since they have been deprived of specific drugs) clearly demonstrate the effects of industry on world health. Fortunately, the commercial criteria used by manufacturers to select the fields in which their innovations are to be produced are counterbalanced by the effects of competition, since a brand new discovery will always attract considerable publicity.

The underprivileged countries are defenceless against economic forces of this kind. Neither their governments nor their individual inhabitants are able to acquire all the medicines they need, the price of which is set without consulting them. To prevent fashionable trends from creating demands among the public and the undesirable effects of having too many substances with the same effects but different trademarks, WHO has drawn up a list of essential drugs to guide those in charge of developing countries' internal markets. Unfortunately, these reasonable suggestions have had little effect on these countries' import policies.

Human nutrition has also been affected by the changes in the world economy. It is true that more rational agricultural practices have been substituted for the less profitable traditional methods and that crossbreeding has improved the yields of both cereals and livestock. The number of countries able to draw their sustenance from their own soil has increased year by year. Previously importing nations are now producing their own requirements

and some have even become exporters. The fluctuating price of cocoa and coffee on the world market has led some countries partly to abandon these crops in favour of produce of greater use to their own inhabitants.

There still exist, however, regions suffering from food shortages and even famine. The affluent countries have hoarded up such vast quantities of cereals, meat and dairy products (carbohydrates, proteins and lipids) that they have acquired surplus stocks they cannot use and cannot (or do not wish to) sell to those unlikely to pay their bills, even at low prices, given the cost of transport involved. As in the case of the drugs mentioned above, it might be appropriate here to refer to 'orphan food'. A few large firms are the main decision-makers in the food processing industry.

Anarchy is not the proper word for this situation, since those who produce food are entitled to expect fair returns for their work, but surely it might have been possible for the food industry to do something about the vitamin deficiencies that are particularly harmful to children, for example by making compensatory financial payments under the aegis of international health organizations?

Health care establishments, like industrial firms, have shown a tendency to amalgamate during the last few decades. A number of international companies have been created to set up and manage private, profit-making establishments, especially in the developed countries. Despite the supervision carried out by the regulatory institutions, the medical professions are sometimes obliged in this context to pursue profit-making objectives. In addition, these private establishments are not obliged to admit all applicants, and can refuse 'high risk' patients, i.e., those who may become too expensive to treat. This attitude has been adopted by some HMOs in the United States. This situation is a far cry from the ideals of public health and care available to all, regardless of class, wealth, and the disease involved.

Harmful industries have been attracting the attention of Western governments for more than two centuries, and regulations have been introduced to protect both the public and workers. By now, most countries have drawn up laws on the prevention of occupational accidents and disease, and on victim compensation. Much still remains to be done, however, since many of these laws are not being strictly applied. The employers, who nearly always have to support the cost of preventive measures, expensive safety devices and worker compensation, do all they can to deny the links between causes and effects. The inspectors responsible for ensuring that the laws are obeyed are not encouraged to be too painstaking. The most dramatic example is that of child workers, who continue to be exploited in many countries, including some with small areas and small populations where the per capita income is fairly high. Employing minors means exposing a non-negligible proportion of humanity to disease, accidents, over-exertion during periods on physical growth, illiteracy, etc. As regards occupational accidents in agriculture, although the populations of the Southern countries are rural dwellers, very little attention is paid to these inhabitants by the countries concerned.

During the last few decades, people have become enthusiastic about the idea of preserving a 'natural environment', in which a constant balance will presumably be maintained between the species and their habitats. This zeal has mainly occurred in the affluent countries, since the poor ones are far too busy trying to ensure their own

survival. The war on noxious pollution has been going on for some time, but will not be over for a long time to come, since it is difficult to identify long-term intoxication processes, and it can take several decades for the exact pathological effects of some toxic substances to be determined.

All industrial waste, liquid effluent and waste gas can be detrimental to rivers, groundwater, and the atmosphere. The list of all known pollutants still remains to be completed, but the fuss made about industrial disasters is out of proportion with the damage actually caused. Although nuclear power plants have sprung up all over the world since Hiroshima and Nagasaki, the only accident to have international repercussions so far has been the one at Chernobyl. In view of the type of power plant involved, other catastrophes on similar lines are to be feared.

The chemical industry has probably produced more pollution accidents and accounted for more victims than the nuclear industry, but its effects are felt more quickly, as in the case of the Bhopal explosion in India.

The obsession with pollution and the exploitation of environmental issues by politicians and the media should not, however, be allowed to generate a state of universal panic, which might prevent research on health-promoting innovations from continuing. The pollution of the Rhine by the chemical industries in Basel had no harmful effects on human beings. The explosion that occurred at Seveso in Italy had lethal effects only on some of the local sheep; but it gave the word 'dioxin' fearful connotations, although some dioxins are both useful and harmless. It is to be hoped that in the twenty-first century, the naive, irrational attitude towards ecology will be succeeded by a more scientific-minded approach.

## Human failings

Despite the existence of well-meaning resolutions to preserve or restore good health in the human race, strict laws and regulations, and sincere and disinterested intentions, the outcome will be successful only if these regulations are properly implemented, which is not always the case. The main obstacle is human nature, which is characterized by a propensity for pleasure, a weakness for risks and a lack of willpower.

People sometimes do not hesitate to take unreasonable risks with their own health by consuming dangerous substances, which, although they may temporarily brighten one's perception of life, in the long run are detrimental to health. Even though the dangers of alcohol have been known for centuries, millions of people consume it in excessively large quantities. The human craving for alcohol is such that no single nation has ever managed to become completely abstinent, whatever administrative or religious restrictions might have been applied.

The same can be said of smoking, since the medical corps has been proclaiming for more than a century that tobacco is detrimental to health. Although in the wealthy countries there has been a slight decrease in male tobacco consumption rates, females tend to smoke more, starting in their early adolescence. Moreover, lung cancer, which used to affect primarily men, is now spreading among women. The combined effects of these two toxins are highly lethal: even in a particularly well-informed population such as that of

France, thirty thousand deaths occurred in 1995 as the result of either alcoholism alone or drinking and smoking combined, which is ten times more than the number who died of AIDS.

The consumption of alcohol and tobacco has increased in developing countries after acquiring independence, either because the inhabitants have sought to imitate the habits of their former colonizers or because these countries have succumbed to a kind of industrial colonialism that has persisted in some areas. Judging from the amounts consumed over the last few decades, this trend seems unlikely to be curbed in the near future.

In comparison with the damage caused by smoking and drinking, the damage resulting both from drug abuse involving either coca, opium or cannabis derivatives and from road accidents caused by driving at immoderate speeds has scarcely affected the history of humanity at all, quantitatively speaking. In taking these risks, people are not obeying a death instinct (which is not a very common phenomenon, whatever the psychoanalysts may say) but are rather expressing the need to be free to make their own decisions, even if they are dangerous ones. It would therefore no doubt be both pointless and risky to take coercive measures in order to restrict this particular kind of freedom.

It would be difficult to list all the unnatural habits adopted by some groups of people, regardless of what the effects on their health may be. This can be illustrated by looking at some kinds of eating habits: errors by default can be committed, for example, by following vegetarian diets too strictly, since this can lead to severe vitamin deficiencies in new-born infants and children, especially in developing countries.

The errors of excess committed in some advanced countries can be just as dangerous as the risks to which the poor undernourished countries are exposed. The habit of eating without any regard for regularity or reasonable quantities has led in the United States, for example, to as many as 58 million overweight people who expose themselves to the risk of cardiovascular disease and high blood pressure.

Other behavioural mores harmful to health include social traditions involving maiming the body. Although tattooing, scarification, and the circumcision of boys are of little consequence as far as public health is concerned, the sexual mutilation of girls can have far-reaching effects. Every year in Africa, more than 2 million young girls are subjected to excision, clitoridectomy, infibulation, and other cruel operations, which can cause infection, sterility, obstetrical complications, and death. There is no particular hygienic or religious reason for these mutilations. They are simply part of the social tradition of some one dozen countries, whose womenfolk are badly oppressed. The governments in question know how harmful these practices are, and the fact that they do nothing about them reflects either a lack of will or inefficient administrative structures.

## Administrative shortcomings

There have in fact been many examples of failures by governments in attempts to improve their population's physical well-being. The explanation for a lack of efficiency may be purely administrative, since it is impossible to apply

health regulations in many countries for demagogic reasons or for lack of funds, or, as it is sometimes quite rightly stated, it is impossible to do good within a community where 'nobody cares, nobody feels it is necessary and nobody participates'. Economically weak nations do not yet have the means of developing their health administrations. This, as we have seen, was one of the reasons health insurance developed so slowly in some places.

On the other hand, experience has shown that the effects of health regulations cannot be fully felt unless the administration functions efficiently and is respected. As soon as a country's structures become shaky and inefficient, its state of health deteriorates: this occurred during each European conflict, and again more recently in the former Soviet Union countries, where the fall in life expectancy at birth is the result of the confusion besetting the old system of management and the delay in appointing new administrators. During the last few years, more than 100,000 cases of diphtheria have been reported in the countries previously ruled by the Soviet Union.

Once again, the newly independent countries are unfortunate. Political instability is a barrier to an efficiently managed state, and governmental upheavals can only worsen economic and social crises. In such a context poor health conditions cannot be improved. Despite the difference between the state of health of the Northern and Southern countries, the wealthy countries cannot restore the poor ones to good health if there is no self-help.

International shortcomings are also to blame. In view of its efforts to aid the developing countries, the hopes raised for the health of humanity when WHO was founded continued to grow for the first few decades of the organization's existence. But as time went by, the donating countries began to express their disappointment. Although the quarrelling between free trade and socialist countries quietened down, contributions were reduced and the deadlines for their payment were extended. The staffs of the various WHO departments were reduced, and the organization was criticized for becoming less efficient. Since staff recruitment at WHO was subject to national quota rules, those engaged were not necessarily the most competent, the most experienced and the most capable of working in unfamiliar countries. This situation generated additional criticism. The organization was also blamed for the fact that recipients did not always use the aid received from WHO for the purposes initially intended by the donors (training health executives, for example). The affluent countries expressed their displeasure by sometimes entrusting other international bodies with health missions. World health did not benefit from all these national particularities and colonialist (not to say imperialist) designs, both past and present, which were continually changing with the evolving economic and political situation.

Cooperative international efforts to promote the health of the needy countries eventually came up against obstacles such as rivalry between the financing countries and between the distributing organizations, and the sensitivity of the beneficiaries. The rift between the socialist Eastern European countries and the capitalist Western nations gave way to competition between Europe, the Far East and the United States.

In this unfavourable climate created by grasping nations, some disinterested non-governmental bodies have developed during the last few decades of the century to compensate for the failures of hesitant states. Thanks to their devoted efforts to aid destitute populations, and despite the risks they face because of the many local wars, they are rendering services official organizations cannot provide. But the resources at their disposal are too small and too irregular, and the positive results of their work seems insignificant in comparison with the desperate needs confronting them.

Given the history of the difficulties encountered in the field of health, the member countries of the European Union are aware that international cooperation is very hard to achieve. Since the EU was created for purely economic purposes, the ministers of health had no legal grounds for meeting one another. It was only at the end of the 1980s that this was achieved, and even then, the meeting could barely be considered an official one.

For a long time, the guidelines imposed by the European Union on its member states focused on subsidiary issues, such as harmonizing vocational training and diplomas in some of the medical professions. This undoubtedly enabled members of these professions to circulate more freely and work wherever it suited them, but the health of patients was not the central issue. In the early 1990s, the member states managed with great difficulty to harmonize the formalities which had to be accomplished before new medicinal products could be launched on the market. The sensitivity of various nations and the distrust between European nations were further increased by the rejection of the ambitions of non-European countries. It was in 1993, in Maastricht, that the twelve member states first introduced into their legal instruments the concept of 'protecting human health', especially 'the safety and health of workers', although this aim was not expressed in forthright terms.

There is certainly no shortage of issues on which the European Union might have taken an authoritative stand to improve health in Europe. The Council of Europe has put forward proposals, for example, as to how blood transfusion should be organized and which biochemical and immunological safety standards should be met by stable and labile blood products. Regulations of this kind have come to seem even more indispensable since many people undergoing blood transfusion were accidentally contaminated with AIDS and hepatitis, and yet the European Union has not even adopted them in the form of guidelines. Nor has the EU done anything to simplify and harmonize the mechanisms whereby the price of medicinal products is set. In addition, the member states have reached no agreement on how to improve occupational medicine as a means of monitoring workers' health.

In some industrialized and wealthy countries, the citizens are still not as fully protected as elsewhere, and it is not by imposing isolated measures on these countries that one can extend to them the full benefits of preventive medicine. Since their representatives are obsessed with their independence and their own economic problems, international organizations are powerless to provide these populations with the expected level of health protection.

## Medicine for the rich, medicine for the poor

Never before in its history has Western medicine undergone so many conceptual and technical upheavals as during the last few decades. New vaccines have been developed against

hepatitis, and a combined anti-measles, mumps and German measles vaccine now exists. Medical research on the chemical basis of genetic transmission has shed new light on the laws involved in heredity and in parentally transmitted diseases and risks. The latest findings in molecular biology have helped to explain how germs may destroy an organism's defence mechanisms, as well as how a drug is able to kill those germs. Research in this field has also helped to explain the processes involved in ageing and in degenerative diseases such as rheumatism, cancer and cardiovascular disease.

Medicine continues to find new scope: resuscitating fragile new-born babies and people injured in accidents, operating on the very elderly, removing and grafting vital organs, treating sterility, correcting abnormal pregnancies, and experimenting on human beings, whether healthy or sick. Laws, traditional social principles, religious precepts and the practitioners' individual conscience cannot guide the case-by-case decisions on matters of great urgency.

Ethics committees have therefore sprung up at an even faster rate since 1980, and some countries, after several years of study, have even gone so far as to promulgate 'medical ethics laws'. However, no single law can make provision for all the possible cases in which a moral issue is likely to arise. In any serious personal or family situation, there exist perfectly good reasons for adopting either of two equally drastic solutions, just as law courts are liable to make either of two quite contradictory judgements, based in each case on perfectly sound arguments.

Ethics committees, apart from those in some Anglo-Saxon countries, generally take collective decisions without being made collectively responsible in return. Physicians are always face to face with their patients. They alone are responsible for diagnosis and therapeutic decisions, and any advice they may seek will never in any way detract from the importance or the magnificence of their task.

Given the existence of these new technical, moral and social problems, present-day medicine cannot be infallible, despite the rational and scientific basis on which it is so firmly founded. People can find these complex principles worrying, and even in the so-called industrialized countries, some members of the population do not altogether approve of them. This explains why some people still resort, except in emergencies, to those forms of medicine known under various names such as non-aggressive, alternative, complementary or parallel, natural. None of these adjectives has any real justification, since scientific medicine is often gentle, and no forms of medicine are ever 'natural', since they all require human intervention. Whatever label they go under, their one common feature is that they have no experimental, rational or scientific justification.

To give just a few examples, one might mention in this context iridodiagnosis, psychopuncture, magnetism, auriculotherapy, the pendulum, homeopathy, reflexology, organotherapy, naturopathy, osteopathy, mesotherapy, and oneirology: some of these labels are actually an affront to etymological common sense. A patient with cancer who has been treated both at a specialized cancer centre and by a charlatan will attribute the cure to the mysterious potion he ingested at full moon rather than to the therapeutic methods developed in the course of a whole century of scientific research. People need mystery and are afraid of having everything too cut and dried. Some governments go along with these fears, accepting uncontrolled practices and allowing them to be taught and their cost covered by health insurance funds, whereas other countries forbid them and prosecute unauthorized practitioners of medicine for carrying out illegal activities. Medicine of this kind will always exist, even among the most meticulous and pragmatic of nations, as long as what has been called scientific medicine continues to deal only with organic lesions, erecting an unscientific barrier between the body and the mind.

Unable to afford all the techniques, instruments and pharmaceutical resources available to Western medicine, developing countries have had to rely on other methods. Traditional medicine exists everywhere, and is as old as Western medicine, since human beings throughout the ages have always assisted one another (Plate 84). Scientific medicine has developed on the basis of original principles and concepts perfected over centuries thanks to a thorough knowledge of human anatomy and physiology.

Ancient practices based on traditions handed down from one generation to the next have never disappeared completely despite the advent of modern medicine. In addition to the doctors of medicine with state-approved qualifications, every Western country has its bone-setters, self-appointed healers and gurus, not to mention those who practise the forms of 'alternative medicine' referred to above, who are the equivalent of the shamans found in many developing countries.

The traditional practitioners in underprivileged countries know how to view their patients in the context of their natural social and physical environment. They are familiar with the cultural background and the ancestral myths. Contrary to the materialist school of medicine, which makes a distinction between mind and matter and often attends only to the body and the diseased organs, the shaman considers humans as part of a whole coherent universe peopled with plants and animals, and possibly with invisible powers, where each element exerts sometimes beneficial and sometimes harmful effects on the others. In this context, disease is assumed to result from a lack of balance between these impenetrable forces. The treatment, intended to restore the previous state of harmony, must include the whole natural range of animal, vegetable and mineral components as well as the realm of the spirits.

For thousands of years, the local vegetation provided human beings with most of their medicinal requirements. The empirical experience acquired by generations has shown which plants can be used in such circumstances – how to prepare them by boiling, infusing, macerating and fermenting them; which part of the plant was the most useful, whether the stems, flowers, fruit, buds or roots; at what season it had the most potent effects; and at what doses its effects became toxic. This traditional lore is irreplaceable. Western medicine would be wrong to do without it, and the present pharmacopoeia includes a large number of phyto-pharmaceutical products.

It is clear that we still are unfamiliar with all the possible medicinal resources offered by the world's flora – including both the commonplace plants from the European plains and the rare, fragile tropical essences – despite the fact that this ancestral know-how was readily available. Indeed, ethno-botany still holds many secrets yet to be elucidated. Unfortunately, the necessary studies are becoming increasingly expensive and therefore do not interest the pharmacological industry, which prefers to develop new methods of synthesizing molecules.

It is quite natural that traditional medicine should make considerable use of familiar plants. The patients realize that they are part of their natural surroundings, and that by ingesting them, they will participate in the life of the universe, and therefore gain an advantageous position. Since the spirits of the forest are helping to heal them, they participate wholeheartedly in the treatment prescribed by the medicine man. Every nation has its own phyto-pharmacopoeia and its practitioners, whose competence in terms of Western medical qualifications may cause sceptics some irritation. Nobody can deny, however, that these purportedly empirical therapists are at least familiar with the toxicity of their remedies and know the threshold doses at which they become dangerous.

In other cultures, the focus has been more on the resources of the human spirit, and other more mental or spiritual techniques have been used, such as suggestion and magic, associated with conjuring and incantation. Many mental disorders have been cured by bushman psychotherapists. All religions encourage belief in myths of 'possession'.

Practices such as relaxation, sophrology, physical and mental release from stress, self-persuasion, meditation of a religious kind, and yoga, undeniably relieve many patients in many ways. Not only is the patients' physical suffering alleviated, but functional disorders can be successfully treated and in some particularly receptive cases (whose characteristics still remain to be defined), autonomic functional disorders resisting conventional drugs (changes in blood pressure, heart rate, respiratory rate, evacuative functions, etc.) respond to treatment of this kind. It is not always possible to find a rational scientific explanation for these results in terms of medical graphs and doses.

The existence of traditional forms of medicine cannot be denied, since they are to be found all over the world and suit millions of patients. No authority would be able to replace these practices by any other type of medicine, which may not be successful in all cases and presents its own disadvantages. However, neither their traditional basis (which has made them so fashionable nowadays) nor their long history guarantees that these empirical methods are bound to be efficacious. They have cured innumerable psychosomatic disorders, but no direct causal relations have ever been established so far between the imbibing of herbal tea and developments in visible, material organic lesions. It should not be forgotten, moreover, that the vast majority of those who consult the local doctor or the tribal doctor suffer from diseases that are liable to be cured spontaneously. This fact should be kept in mind whenever a therapeutic method is being critically evaluated.

Patients are therefore free to choose for themselves, which is precisely what they do. Both in industrialized, supposedly educated and cultivated countries and in backward, illiterate ones, two types of behaviour can be observed, which shows that when confronted with illness and the fear of death, humanity is the same everywhere. When a worrying or painful symptom or a functional anomaly occurs, some people first consult a so-called 'official' medical practitioner, providing that he or she lives nearby and is not too expensive. If they are still worried or the problem has not cleared up quickly enough, they wonder whether they have been taking the right medicine and consulting the right person, and they call on a practitioner of alternative medicine. By combining the two types of treatment, they hope to increase their chances of being cured, but forget that they are also increasing the risk of failure.

Other people do things the other way around. Not wanting to bother their doctor, they go to see the local bone-setter who cured their parents so well, and it is only when the results turn out to be disappointing that they decide to turn to a qualified practitioner. These attitudes can be observed everywhere.

In wealthy countries where properly trained doctors and fully equipped hospitals abound, the consequences are not too serious; it is a great pity, however, to see patients with a serious condition diagnosed too late because they wasted their time by first trying a more 'gentle' type of treatment.

It is a different matter in poor countries where the local medical traditions are familiar to all, practised everywhere at very little cost, and trusted by the patients. Ethnic medical practices should not be criticized, still less abolished, but should be put to good use. The men and women who apply them are highly respected; they are strongly committed to loving their fellow human beings, often disinterested and rarely dangerous. These people should be trained in the sound principles of Western medicine, for they would contribute greatly to improving their people's health if they were taught how to keep dwellings clean, why breast-feeding is to be recommended, the need for food to be clean and varied, the principles of hygienic childbirth, and possibly what can be done about contraception, for example.

It will require a complete integration of the two approaches to medicine – two distinct ways of looking at disease and humanity's place in the environment – before many of the world's ailments can be healed. But the economic constraints weighing on the developing countries do not leave their authorities much room for choice as far as their health policies are concerned.

Over the centuries, people in African and Asian countries have built up quite a different picture of disease from that commonly held in Western countries. Since their pharmacopoeia is very ancient, people have much less esteem for the medicinal products that are manufactured at great expense by a scientific industry that is completely alien to them. Some of them think vaccination is an illusory, dangerous attempt to oppose nature's designs. Likewise, many consider being confined to hospital to be more harmful than remaining in the comfort of one's own home.

It has been claimed that nations have gone through a period of 'epidemiological transition' over the centuries. In the poor countries, the so-called 'age of mortality' was expected to come to an end in the twentieth century, whereas the wealthy countries were said to be about to enter an 'age of morbidity'. The situation is indeed changing rapidly. The causes of mortality are disappearing in the developing Southern countries, and morbidity is increasing as more newborn infants survive and people tend to live longer. The desire and the need for medical care are bound to continue to grow, and increasing demands will be placed on medicine, no matter which tradition it belongs to and whatever its resources may be.

**Taking stock: the world's population**

Since the public health organizations have continued to develop throughout the twentieth century, one might be

tempted to take stock of their achievements so as to be able to improve them further and adjust them in the course of the new century. Such an overall assessment is not possible, however, for several reasons.

First of all, even assuming that it might be possible to define universal health indicators (i.e., indicators accounting for all the aspects of a population's life), it would be difficult to establish causal relations between the activity of a health service and a population-based phenomenon because the existence of human groups and the quality of life they enjoy depend on a set of complex factors yet to be elucidated.

Secondly, it would be necessary to establish a set of health criteria with which the two hundred or so member states of WHO unanimously agree, as well as health data collected by means of a completely reliable method designed for universal use, which for the moment is quite out of the question. All over the world, the performances of the statistical tools available are considered unsatisfactory because the differences between the various public health systems are too great. Even in reputedly well-equipped countries, the quality of the statistics varies from one region, province or country to another, and even more so, from one social sector to another.

All that we can do, therefore, is to make a few general comments, which may be regarded as either encouraging or disturbing, depending both on how they are interpreted and on which governments are attempting to draw conclusions with a view to reforming their public health structures.

The world's population is increasing, despite epidemics, civil wars, famine, omnipresent poverty, and the fears generated by the latest viruses. The tragedies that have occurred in some places – for example, in Cambodia at the end of the Khmer Rouge regime, and in the Soviet Union during its dissolution – were only temporary and had human rather than extraneous causes.

The world's population explosion is slowing down. Couples are having fewer children, either in response to governmental incitements, or thanks to the spread of voluntary contraception in some countries and among social classes that ignored the techniques a few decades ago. Since infant mortality is declining, families no longer need to have six or seven children to ensure that there will be two or three survivors. It is hard to tell, however, whether this apparently rational tendency is the result of a spontaneous process or that of a deliberate decision made by those procreating. In some regions where endemic viral diseases, such as AIDS (particularly in Africa), are taking their toll, the fact that the disease is most prevalent among the procreative age groups is liable to have serious effects. Little is known as to whether householders' income affects their fertility. But poor countries are known to produce more children than rich ones. Since the gross national product (GNP) is increasing even in the most destitute countries, the per capita income is presumably increasing. This reasoning would be valid if the GNP were distributed equally among all the citizens, which is not the case.

The reduction in the growth of the world's population should therefore reassure alarmists who imagined that humanity was expanding too fast and about to starve to death. Agricultural production is also on the increase, and too much produce is being grown, resulting in fertile land being left fallow for lack of a better system of market distribution for farm produce. By the turn of the century,

the world had slightly more than 6 billion inhabitants, which is less than the ominous numbers previously predicted.

Life expectancy at birth is rising everywhere, even in the least-developed countries. One might be tempted to conclude that, since people are living longer, humanity is in good health, and that the health authorities have grounds for self-satisfaction. This attitude would be quite justified if it were not for the shocking inequalities that have subsisted.

Every country has its poor people, and the rich benefit more than others from health services and sickness insurance schemes. Progress in medicine has done more for the well-being of the affluent and healthy than that of the poor and unhealthy. No public health or health care system has ever succeeded in abolishing the health-related inequalities between the nations, and within national frontiers the gaps are widening from one social category to another.

The situation is even more deplorable in the developing countries, where the increasing GNP is improving the health and the quality of life of the wealthy to the detriment of the poor, and where the gaps are even more conspicuous than in the industrialized countries. In this respect, the situation of the Southern countries resembles that of the Northern countries during the nineteenth century: the mean life expectancy at birth is around 75 years in the Northern countries, and barely 50 years in the Southern ones.

There also exist striking differences between town and country. Since the mid-twentieth century, towns have continued to develop much faster than rural areas. All over the world, cities began to mushroom between the two world wars, and in Africa and Asia, urban sprawl worsened after the Second World War. Contrary to earlier trends, however, health tends to be better in the towns, where there is improved hygiene and sanitation, and high concentration of wealth. In Britain, 90 per cent of the population are town dwellers. In Third World countries, one-third or more (50 per cent in Gabon) of the population lives in the capital city, except in Kenya, where only 28 per cent of the country's population live in Nairobi.

The tendency of populations to concentrate in this way is not without risks. Congested housing conditions and the lack of amenities favour the spread of tuberculosis by contagion. Promiscuity and poverty are factors conducive to prostitution and the spreading of sexually transmitted diseases such as AIDS. Circumstances of this kind tend to favour addiction to alcohol, tobacco, and psychotropic substances of all sorts.

The sight of African slums and Latin American *favelas* and the living conditions to be found there quite rightly inspire indignation. But is this indignation really justified? There are plenty of explanations for the attraction the towns have exerted on hungry, ill-nourished, under-employed rural inhabitants for over half a century. They come to join members of their clan or tribe already living there; however irregular and badly paid the work may be, it is still work. Moreover, much money circulates in the towns. The trade and industry that enrich the country leave a few crumbs for the poor; such is not the case in the countryside. As time goes by, rough tin and cardboard shacks are reinforced with breeze blocks and cement, and the water in the drinking fountains is eventually rendered fit for human consumption, since more attention is paid in developing countries to the health of the towns than that of the country, no doubt

because, contrary to what occurred in previous centuries, indignation and revolt tend to be expressed more vehemently in urban areas than in villages.

Whatever the case may be, although the most populous countries such as China, India and Indonesia have seen to it that their teeming numbers continue to live mostly in the country, it seems hardly likely that people will begin deserting the towns. In fact, the world's large cities are expected to become even more densely populated over the next few decades.

## CONCLUSION

It will be possible to take stock of public health activity during the twentieth century only with hindsight. At present, it can be stated, however, that humanity was in better health at the dawn of the twentieth-first century than at the beginning of the previous one. The fact that the simple rules of hygiene have come to be more widely observed has contributed as much to this improvement as the numerous medical innovations, but preventive vaccination from which tens of millions of people have benefited has been the main medical achievement. Improved standards of living, better nutrition, the development of tools for making both industrial work and humble household tasks easier to perform have also made a difference to one-quarter of the world's population: those living in the industrialized countries.

One cannot but regret, however, that human know-how and the resources of the planet have not been devoted more specifically to improving the health of humanity. We have attempted to provide a few partial explanations for this state of affairs, which are not intended as excuses or grounds for justifying the shortcomings. The human race, including both individuals and governments, could do better. Economic factors are bound to influence the world for a long time to come. Public health will continue to be neglected until it is recognized that the health of people and nations is a calculable asset.

## TECHNOLOGY AND APPLIED SCIENCES

## 17.1
### KNOWLEDGE AND PRACTICE

*Eriabu Lugujjo*

### INTRODUCTION

A glance at the dictionary shows that the verb 'to know' can be used in a variety of ways. We speak of 'knowing' in the sense of 'being familiar with something', to be 'aware of something' or to apprehend or comprehend as fact or truth. In his arguments about knowledge and in response to the question, 'What is knowledge?', the English philosopher Alfred Jules Ayer put forward the following questions:
 – Do the different cases in which we speak of knowing have any one thing in common?
 – Is there any difference between knowing and believing?
 – Does knowing make any difference to what is known?
 – Does knowing constitute truth?

The verb 'to know' is dispositional, and the dispositions taken to constitute knowing must be revised.[1] Knowledge is a multifaceted concept with multilayered meanings. The history of philosophy since the classical Greek period can be regarded as a never-ending search for the meaning of knowledge. In this chapter, we will follow traditional epistemology and adopt a definition of knowledge as 'justified true belief'. Knowledge is a dynamic human process of justifying personal beliefs as part of an aspiration for the 'truth'. Knowledge is created and organized by the flow of information anchored on the commitment and beliefs of its holder. This statement emphasizes the essential aspect of knowledge that relates to human activity.

The formal features of knowledge can be analysed in two dimensions: the epistemological and ontological. The former concerns the modes of expression of knowledge. The epistemological dimensions are explicit vs. tacit knowledge. Human knowledge exists in different forms; it can be articulated explicitly or manifested implicitly (tacit). Polanyi argues that a large part of human knowledge is tacit.[2] This is particularly true of operational skills and know-how acquired through practical skills. Knowledge of this type is action-oriented.

Explicit knowledge can be generated through logical deduction and acquired by formal study. It can be easily transferred across time and space. However, tacit knowledge can be transferred when there is close interaction and a harmonious relationship between learner and instructor. It can be acquired through vocational instruction in any given context.

In 'The Ontological Dimension: The Individual vs. Collective', Lam argues that knowledge within an organization can reside at the level of the individual, or be shared among members of the organization.[3] Tacit knowledge moves with the individual. However, collective knowledge is distributed and shared among members of the community through rules, procedures and routines known by all.

From the explicit-tacit and individual-collective dimensions of knowledge there emerge four categories of knowledge: 'embrained', 'embodied', 'encoded' and 'embedded' knowledge, as shown in Table 5:
1. Embrained knowledge (individual and explicit) is dependent on the individual's conceptual skills and cognitive abilities. It is formal, abstract, or theoretical knowledge. It is typically learnt through reading and in formal education. Embrained knowledge enjoys a privileged social status within Western culture.
2. Embodied knowledge (individual and tacit) is action-oriented; it is the practical, individual type of knowledge on which Polanyi focused. It is learnt through experience and in training based on apprenticeship relations. Embodied knowledge is also context-specific; it is particular knowledge, which becomes relevant in light of the practical problem-solving experience. Embodied knowledge has contributed greatly to the development of the so-called Third World.
3. Encoded knowledge (collective and explicit) is shared within organizations through written rules and procedures and formal information systems. It is formed by making tacit knowledge as explicit as possible. This is well illustrated by the principles of scientific management, which attempt to codify worker experiences and skills into objective scientific knowledge.
4. Embedded knowledge (collective and tacit) is built into routines, habits, and norms that cannot easily be transformed into information systems. It is produced through social interaction and supported by its shared cultural norms. Embedded knowledge is relation-specific and dispersed. It is an emergent form of knowledge capable of supporting complex patterns of interaction in the absence of written rules. This form is a replica of traditional knowledge.

The traditional form of knowledge combines types 2 and 4, while the modern form of knowledge follows 1 and 3.

*Table 5* **Four categories of knowledge**

|  | Individual | Collective |
|---|---|---|
| Explicit | Embrained knowledge | Encoded knowledge |
| Tacit | Embodied knowledge | Embedded knowledge |

## THE EVOLUTION OF KNOWLEDGE AS A CATALYST FOR DEVELOPMENT

Although the First World War disrupted the steady scientific and technological progress of the West, it demonstrated the role and power of science, innovation and technology. At that time, research was being undertaken in major universities in Europe, the United States and Russia. Scientists and engineers enjoyed affiliations with recognized associations and societies, such as the American Philosophical Society, the American Academy of Arts and Sciences, Verein Deutscher Ingenieure in Germany, the Royal Society in London, the Russian Academy of Sciences, the Académie royale des sciences in France, the Accademia dei Lincei in Italy, the Akademie der Wissenschaften in Berlin, the Kungliga Ventenska Psakademien in Sweden, just to mention a few. These organizations provided forums and the impetus for the exchange of ideas and the transformation of scientific research into usable products.

The first twenty years of the twentieth century were eventful, for they marked the emergence of a new world with the discovery of the electron, Einstein's theory of relativity and Bohr and Rutherford's research on the atomic structure, Broglie's wavelength, Max Planck's work on radiation, Schrödinger's new characterization of the electron and Max Born's research on statistical mechanics. Basic research of this nature had a profound impact on the scientific community, prompting it to search for further meaning and truth.

The world, however, longed for both basic research and product innovation. By 1900, General Electric Research Laboratory (GE) had been established and formally institutionalized industrial research. The GE laboratory, the first of its kind in the world, served as a model for industrial research in other high-technology fields.[4]

It is interesting to note that while inventions were being made in highly organized establishments, some non-academic inventors also appeared on the scene. Examples include R. Ruedenberg, a German who patented an electron microscope in 1931; Laszlo Biro, a Hungarian who invented the ballpoint pen in 1938; Frank Whittle who invented the first jet engine in 1937; and German inventor Karl Zuse, who patented a calculator in the same year. Some of these innovations did not arise out of societal needs. They were the product of talented minds working freely without restriction.

While the West was occupied in intense scientific and innovative activities, inhabitants of the Third World (at the time still colonies) were living and sustained through application of inventions based on indigenous knowledge and practices and through exploiting their resources. Such local knowledge is still unique to particular cultures and highly valued, even though the West does not seem to agree with its practice and results. It is therefore not surprising that the last century has witnessed a systematic denial and abandonment of indigenous knowledge and a preference for Western knowledge and innovation. Early indigenous innovations have been suffocated, and new generations in developing countries have been indoctrinated to the point of not believing in these products of their own culture.

There are however exceptions to the above statement. India has progressed quite well in both modern scientific research and indigenous knowledge. Between the 1920s and 1940s, a truly Indian scientific community emerged in parallel with colonial science. Moreover, the Indian scientific community acquired a distinct identity in the international sphere of science through applying knowledge from the laboratory to national needs.

As regards China, it had played an important role in the history of ancient world civilization and made many outstanding discoveries and inventions in the realm of science and technology. However, owing to many socio-economic and political factors, China's science and technology lagged behind up to the birth of the People's Republic of China in 1949. Even after this period, the Cultural Revolution disrupted most of the intellectual activities of the country. Real economic construction and programming started in 1978, when science, technology and innovation to solve people-centred problems were emphasized.

Innovative programmes in Europe were affected in 1933 when Hitler came to power. Scientific workers either devoted all their efforts to war armaments or left their countries of origin. It has been noted that active research in Europe not directly linked to defence resumed after the end of the Second World War. This clearly demonstrates that innovation requires an enabling environment of peace, optimism and hope, recognition and financial support.

### Knowledge, necessity and innovation

Technology and inventions are intimately associated with a broad spectrum of human needs, whether these are dictated by the physical conditions of existence or by 'cultural' factors derived from the historical specificities of different social groups. These cultural or acquired needs can be 'natural' and organic, or they can be induced and manufactured either through advertising or by centrally planned manipulation of needs.

The issue of knowledge, invention and necessity sometimes poses a dilemma. There have been cases where inventors were neither driven to create by necessity nor directly linked to the immediate uses of their inventions. Innovation requires a free mind uncluttered by preconceived ideas and arises from independent thought. For example, the inventors of Kodachrome were musicians, the inventor of the Xerox photocopier was a patent lawyer, and the inventor of the ballpoint pen mentioned above worked as a painter, journalist and even a sculptor.

The last century has also witnessed inventions made by independent workers unaffiliated to big corporations. American brothers Wilbur and Orville Wright (Plate 85) patented their aeroplane early in 1904; Juliot-Curie patented nuclear fission applications in 1934; and Robert Watson-Watt patented radar in 1947.

In developed countries, inventions have long been registered and recognized through a secure patent system by which the inventor and the entrepreneur/industry can safely negotiate appropriate terms to translate the invention into a product. The process of transforming an invention

into a profitable product has always been complex as it involves many actors. Technical and socio-economic issues have to be studied and a margin of profitability established.

In the developing world, many innovations arising out of indigenous knowledge have been made, although no international patents have been issued. Innovations in agriculture, medicinal plants, traditional hydrology, and herbicides, just to mention a few areas, are well documented at the local level. However, the transformation of these inventions into products has been and remains a major problem owing to a number of reasons, particularly the restricted size of domestic markets, the comparatively high cost, the scarcity of foreign exchange, lack of financial resources and the limited number of industrial entrepreneurs.

**Cultural dimension in technical change and development**

At the turn of the twentieth century, the Western world had built up a scientific and inquisitive culture based on political will, intellectual capacity, and an organized institutional base. The political will manifested through a political culture framed coherent science policies, which embodied all the aspirations of the various countries in the region. These science policies constituted 'White Papers' for scientific development. It is therefore not surprising that the United Kingdom, the United States, France and other countries have continued to allocate sizable financial resources to science and technology.

Developed nations have always valued intellectual capacity as a resource and indeed encouraged collaboration among scientific workers. The degree of recognition has markedly changed, as knowledge has become increasingly market orientated.

Developing countries that recognized the role of science and technology as an engine of development and embraced it at policy and technical levels have made remarkable progress in the last thirty years. India, Argentina, Taiwan, Singapore and the Republic of Korea spend greater than 0.5 per cent of their GNP on science and technology development. Essentially they have embraced the science and technology culture through importation and adaptation coupled with collaborative research and development. Other regions, especially the least developed countries, have remained backward in science and technology, prompting Rosenberg to observe the following:

Many of the major innovations in Western technology have emerged in the capital goods sector of the economy. But under-developed countries with little or no organized domestic capital goods sector simply have not had the opportunity to make capital-saving innovations because they lacked the necessary capital goods industry. Under these circumstances, such countries have typically imported their capital goods from abroad, but this has meant that they have not developed the technological base of skills, knowledge, facilities, and organization upon which further technical progress so largely depends.[5]

As we begin the twenty-first century with the knowledge revolution, the least developed countries have a chance to participate in world affairs through information and communication technology. However, merely having access to knowledge will not significantly impact their development unless people, governments, industries and educational institutions are encouraged and able to put that knowledge to effective use. To a great extent, the capability to do so is closely related to people's education and skills. But even more important are the roles of incentives and the institutional structure of the economy.

## CONCLUSION

Knowledge and practice has spurred revolutions in human history. The revolutions based on materials and production of the first half of the twentieth century have been replaced with a knowledge-based revolution. The knowledge revolution was born with the invention of the transistor and the subsequent improvement of manufactured integrated circuits, which led to the new technologies that enable us to process and access information remotely.

The way nations utilize knowledge to innovate has greatly determined their progress and socio-economic well-being, while also creating a new form of knowledge imbalance between developed and developing countries. The future of humanity demands careful planning of institutional structures that are flexible enough to access, organize and apply knowledge. This is the present challenge for all of us.

# AGRICULTURE

*Eriabu Lugujjo*

## EARLY AGRICULTURAL PRACTICES AND KNOWLEDGE

Most of the agricultural practices in the early part of the twentieth century were inherited from the research, techniques and developments of the Industrial Revolution. Some of the notable innovations, practices and knowledge are briefly discussed in the present article.

Popularized by Charles Townsend in the eighteenth century, four-field crop rotation of turnips, wheat, barley and clover was a common practice in the twentieth century. This rotation produced both fodder for livestock and cereal grain, and helped to control weeds and to maintain soil fertility. Nicholas Appert, a Frenchman, developed the technique of canning food by preserving products in sealed jars and heating to high temperatures to kill bacteria. In Leicestershire, England, Robert Bakewell pioneered the selective breeding of cattle and sheep to produce leaner animals. In the early 1800s, a new kind of agriculture, known as plantation agriculture, was developed in Tennessee (USA), where cotton was the predominant crop.

In the 1880s, Austrian scientist and monk Gregor Mendel discovered the basic principles of heredity through carefully controlled experiments in cross-breeding. His work paved the way for improving crops through genetics. Hybrids are the offspring of parents from different breeds, varieties or closely related species and are often superior in many ways to their parents – a phenomenon called hybrid vigour. For example, hybrid pigs grow faster, and their meat is leaner. In the 1920s and 1930s, scientists improved many crops such as corn (maize) by hybridization.

In addition to corn, important local crops in the early 1900s were wheat, oats, rye, barley, onions and potatoes, while important livestock were hogs and dairy and beef cattle, sheep and laying hens. In the early 1900s, notable improvements were being made with crops and livestock, and new practices were introduced such as the liming of soil to reduce acidity, terracing hillsides, building better drainage systems and installing erosion check dams. Irrigation systems, mixed farming and stock raising practices were improved.

Rain-fed agriculture was practised in arid lands. This is sometimes called 'hazard agriculture'. The productivity of farming in semi-arid environments is limited by water availability, and interactions with herders have not always been conflict-free. Hazard agriculture involves the manipulation of soil by tillage, reduced water loss (from weeds, etc.), the proper choice of plants (breeding), traditional cropping until the yield declines, and abandoning fields periodically. Moreover, water input is controlled solely through the timing of planting. Concerned areas include: the Sahel, parts of Angola, Tanzania, Northern Africa, Arabia, Iraq, Iran, Afghanistan, and Pakistan.

### Early agricultural equipment

In the 1800s, farmers and blacksmiths introduced various modifications to the plow that provided a sharper and stronger cutting edge (share) and smoother surfaces so that soil did not stick to either the plowshare or the moldboard. John Deere's plows became a standard of excellence in the 1850s, but Deere was neither the inventor nor the only manufacturer of steel plows. Deere's contribution to the plow consisted of manufacturing a large number of high-quality plows at a competitive price. Steel plows, however, were expensive, and both Deere and other manufacturers sold many cheaper iron plows that were manufactured by various processes for strength and smoothness for the benefit of the growing number of prairie farmers.

The western frontier moved through Illinois in North America. Many of the early immigrants to Illinois brought relatively simple equipment that they had used in the east: the wagon, plow, harrow, axe, rake, scythe, fork and shovel. Most of the equipment used in the early 1900s was the result of ideas developed in the preceding decades. Many of the techniques and methods that were discovered in the nineteenth century continued to be applied in the 1900s.

The seed drill, invented by Jethro Tull, was the first agricultural machine. It cut furrows, sowed and covered seed. Delivering increasing yields and enabling more efficient use of seed, the seed drill showed how farming could be made more productive through the use of machinery to replace hand labour. James Watt patented an improved steam engine, and steam technology later led to the development of powered farm machinery.

The combined harvester, which cut and threshed grain crops, came into widespread use in the western United States in the early part of the twentieth century. It reduced the amount of labour needed to harvest a field of wheat by more than 80 per cent. More efficient and less cumbersome than steam-powered tractors, gasoline- and diesel-powered tractors gradually became the principal agricultural workhorses in many parts of the world. The tractor, first introduced in the 1920s, is to the farmer of today what the horse was to the farmer of 1900. Mechanization has also produced more specialized pieces of equipment such as combines and planters, which in some cases incorporate the latest advances in computer and satellite technology.

**Early developments in agriculture**

In parts of the United States, a minimal crop response to manures and commercial fertilizers with soils that had been used for continuous corn production for 15 years was reported in early 1900s. More research was done on the use of fertilizers, and crop yields increased in subsequent years. Growers started planting a mixture of crops both for home consumption and for the market. Wheat, corn, oats, barley, rye, flax, and potatoes could be commonly found on farms in addition to vegetables and fruit grown for home consumption. Some attempted to redress limited availability of lumber by planting trees, and such initiatives led to a slight expansion of the forested area. The emergence of railroads meant that people could bring lumber and fuel from other parts of the country in exchange for agricultural commodities.

Horsepower had replaced oxen power, some commercial fertilizer was used as well as livestock manure to maintain soil fertility, and crop rotation with legumes had become a common practice in some parts of the world. Horses and mules were used for draft power, and a good portion of the oats that farmers grew went to feed the horses, although a considerable amount of it was sold for human consumption as well. Land that was too wet to cultivate was initially used for livestock grazing.

A distinctive system of agricultural manufacturing that emphasized mass production, low cost, and interchangeability of parts was developed in the Americas and soon spread to many European countries. This system of manufacturing created many products, some of which were used on farms to increase the productivity of each labourer, in harvesting, planting and cultivating fields. Advances in textile manufacturing equipment increased the demand for cotton. Manufacturing also created a demand for labour. An increasing percentage of the population would find employment in the manufacturing sector and fewer in agricultural production.

As farms became increasingly mechanized, one family could farm more acres. For example in Illinois (United States) in 1900, the number of farms reached 260,000, each averaging about 125 acres in size. The number of farms declined gradually at first to 200,000 in 1950, and then dropped precipitously to 82,000 in 1990. Correspondingly, the average size of a farm increased from 150 acres in 1950 to 340 acres in 1990.

It should be noted again that development was not restricted to the Western world. The Mossi people of Burkina Faso developed stone bounding early in the twentieth century. The bunds (lines of stones) were built up over the years and reached one metre in height, effectively terracing the slopes for relatively little labour input, most of it during the dry season. In later periods of political turmoil and land alienation, the bunds were abandoned. However, after a series of droughts in the 1970s, the stone bunds were spontaneously revived and combined with 'zay' or pits which conserve water and in which organic material is placed to increase soil fertility. Because of the further developments in this technique, sorghum yields have risen by up to about 40 per cent in fields with bunds.

The tin can for food preservation, through the canning process, and the first practical reaper of grain or grain harvesting machine were invented in the early 1900s. A pioneering German chemist, Justus von Liebig, made many important contributions to organic chemistry and to the basic principles of agricultural chemistry. He was one of the first to propose the use of chemical fertilizers. The development of the chemical fertilizer industry in the 1840s, following the work of von Liebig, in Germany, and early agricultural scientists such as Lawes and Gilbert, in England, had a major impact on agricultural productivity in the early part of the last century.

The railway and steamship lines expanded, opening up new markets. Improved methods of refrigeration and canning made possible the long-distance marketing of perishable agricultural products. French microbiologist and chemist Louis Pasteur pioneered the study of microbes in the late 1880s. He showed the role of micro-organisms in fermentation, devised pasteurization as a way of preventing beer and milk from souring, popularized sterilization and developed a vaccine.

Introduced by the Swiss in 1939 as a synthetic chemical insecticide, DDT virtually wiped out many insect-borne diseases. Before its harmful effects were discovered, it was heavily used in agriculture around the world. DDT was still being used in the developing countries in the 1980s. In the 1940s, through scientific advances and improved management techniques, farmers produced more food than ever before using less land and labour, but more chemicals, energy and capital.

Francis Crick and James Watson in 1953 discovered the structure of DNA – the genetic basis of all living things. This made possible genetic engineering, which, for agriculture, could mean genetically improved plants and animals, more resistant to disease, and more productive. The late 1950s saw the introduction and widespread use of artificial insemination for breeding livestock. Thanks to this technique many offspring from selected males can be produced.

## AGRICULTURAL DEVELOPMENT

**Scientific and technological developments in agriculture**

The global agricultural system relies heavily on mechanization, in the processes of clearing, planting and harvesting. The aim in today's technologically advanced agricultural system is to reduce labour inputs and productions costs.

In developing countries, especially in the early 1980s, farmers began using computers to keep farm accounts, to

monitor crop prices and weather conditions, and to assist in farm management.

Presently, scientists working in agriculture have delved into other fields, including medicine, biochemistry, biophysics, computer science, and the social sciences. As new scientific discoveries and developments take place, many of them have direct and indirect effects on agriculture and our lives.

Biotechnology came into the limelight in the last century, and the possibilities for its agricultural applications are only beginning to unfold. The role of biotechnology in agriculture has been described as a precursor to another Green Revolution that would be a boom for eliminating world hunger.

Biotechnology finds agricultural applications through its awesome potential to manipulate single genes at the molecular level. It has virtually eroded all biological barriers that prohibited inter-specific crossing. Genes can be transplanted from one organism to another to carry out special biological functions; micro-organisms can be engineered by alterations in their genetic structures and introduced into a given plant species to change the genetic regulation in the host; genes may be selectively eliminated or added. Biotechnology has resulted in increased disease-resistance in plants, and enhanced environmental tolerance, such as the ability to grow in salty land or endure long periods of water deficiency.

In the area of livestock and animal husbandry, researchers are looking for ways to increase production of vitamins and amino acids for animal feeds. Similarly, research is underway to exploit the animal growth hormone to stimulate meat production and develop vaccines against animal diseases. Therefore biotechnology gives total control over the production and reproduction of agricultural products and other biologically active micro-organisms.

## Effects of scientific and technological developments on agriculture

The technological advances, along with an abundance of inorganic fertilizers and pesticides, have made it possible, and indeed cost-effective, for farms to expand. Moreover, indigenous knowledge (IK) techniques have been introduced in agricultural practices, because in most developing countries, the overwhelming majority of the population is involved in small-scale farming of less than two hectares of land. These farmers represent hundreds of distinct languages and ethnic groups. In most instances, the knowledge systems of these farmers have never been recorded systematically in written form; hence they are not easily accessible to agricultural researchers, extension workers, and development practitioners. While they remain invisible to the development community, many indigenous organizations are operating in rural communities to search for solutions to community problems. Indigenous knowledge is unique to a given culture or society and constitutes the information base for a society that facilitates communication and decision-making. IK is the systematic body of knowledge acquired by local people through the accumulation of experiences, informal experiments, and intimate understanding of the environment in a given culture. Results of the incorporation of science and technology in agriculture have made it very productive and competitive.

## Modern agriculture

Until about four decades ago, crop yields in agricultural systems depended on internal resources, recycling of organic matter, built-in biological control mechanisms and rainfall patterns. Agricultural yields were modest, but stable. Production was safeguarded by growing more than one crop or variety in space and time in a field as insurance against pest outbreaks or severe weather. Inputs of nitrogen were ensured by rotating major field crops with legumes. These rotations suppressed insects, weeds and diseases by effectively breaking the life cycles of these pests. A typical US Corn Belt farmer grew corn rotated with several crops including soybeans, and small grain production was necessary to maintain livestock. The family with occasional hired help carried out most of the labour, and no specialized equipment or services were purchased from off-farm sources. In this type of farming system, the link between agriculture and ecology was quite strong, and signs of environmental degradation were seldom evident. Modern agriculture uses scientific and technological advances to improve on these practices and methods.

A noteworthy example of modern agriculture in Africa can be found in Zimbabwe, where both cropping and animal husbandry are practised extensively in the suburbs. Current projects call for informing local policy-makers on key urban agriculture issues, providing relevant training, facilitating dialogue with urban farmers and recommending key changes for improved urban agriculture management in the country. Expected results include a computerized mapping system, a planning manual on urban agriculture and support documents, as well as control measures by local authorities.

## Social, economic, and environmental effects of agricultural development

Agriculture constitutes the economic base in many regions of the world. For some nations, agriculture is the most important industry, providing a high percentage of the gross domestic product (GDP), employing directly or indirectly a large part of the total work force. In addition, agriculture is an important source of raw materials for many manufacturing industries, and in turn is an important market for manufactured goods. Measuring the effects of technology choices on productivity is crucial to understanding the determinants of agricultural growth. Investments in technology have yielded large gains for agriculture, and the benefits have been passed on to consumers in the form of lower prices. In this way, public spending on agricultural research has been justified. Agricultural expansion brought 'unproductive' land into production, and yields per hectare even increased. As a large amount of land is used for cash crop production, the number of absentee owners has increased.

However, as agricultural modernization progressed, the ecology-farming link was often broken as ecological principles were ignored and/or overridden. In fact, several agricultural scientists have arrived at the general consensus that modern agriculture entails environmental crises. A growing number of people have become concerned about the long-term sustainability of existing food production systems. Certain evidence seems to indicate that whereas

the present capital- and technology-intensive farming systems have been extremely productive and competitive, they also give rise to a variety of economic, environmental and social problems.

Conventional agriculture has caused economic problems associated with the over-production of crops, increased costs of energy-based inputs and decreasing farm revenues. It has also produced problems such as insufficient ecological diversity, soil and water pollution and soil erosion.

The plowing up of mollisols has led to massive soil erosion in many places around the world. Dry farming methods aggravated this problem in the 1900s. The use of fertilizers also masks the loss of soil nutrients. Additional problems include soil salinity and rising ground water. The erosion threat remains serious, even if some soil conservation measures reduce crop yield.

## CONCLUSION

There have been many developments in the field of agriculture in the twentieth century; particularly significant has been the increase in land and labour productivity. A comprehensive examination of data from many countries shows that during the period from 1967 to 1992, some 81 per cent of the world's population lived in countries where agricultural growth exceeded population growth. However, it must be added that this average figure masks the situation in developing countries.

The major question facing us today concerns the types of environmental and resource-related agricultural policy adjustments that can properly deal with the costs of resource degradation and increase long-term prospects for sustainable development. Various public policy approaches have been proposed, discussed and analysed with regard to their environmental and resource impacts in both industrialized and developing nations.

A growing number of countries and research institutions are undertaking biotechnology research. This is often, however, more a consequence of 'science-push' than 'demand-pull.' Individual research projects and programmes are often undertaken in the absence of clearly defined national priorities for biotechnology. In addition, biotechnology is not generally integrated within the broader national policies and institutional frameworks.

There appears to be a need for greater selectivity in biotechnology research to avoid the risk of 'reinventing the wheel'. Research effort is highly concentrated in the public sector, sometimes in newly established biotechnology institutes, with very little involvement on the part of the private sector, although efforts are being made to strengthen public/private sector collaboration in many countries. Recent advances in biotechnology have led to the cloning era, which brings to the fore new threats and ethical implications.

In the developing countries, efforts should be made to increase and diversify agriculture by introducing new crops, expanding livestock, poultry and dairy production, and developing local industries to process agricultural products. Institutions of higher education should also promote agricultural training and development through more practical-oriented programmes. At the policy level, the agricultural sector should be given more resources to support programmes at all stages of development.

## THE OCEANS
## RESOURCES AND MARICULTURE

*Eriabu Lugujjo*

### INTRODUCTION

Mariculture is the cultivation of food organisms, e.g. fish, shellfish, and algae, under controlled conditions to be commercially harvested for human consumption. While mariculture is a growing industry, it is an expensive process and results in a product that is not affordable by the world's poor.

Extensive mariculture has a relatively long history. For example, the ancient Romans were familiar with oyster culture. However, commercial production of seafood or industrial chemicals by mariculture is a recent development. Mariculture is a competitor for space in the near shore coastal zone, and it is generally considered that its development and daily operations should be compatible with existing coastal zone uses.

### THE OCEANS

The oceans are believed to have formed in the process of the Earth's cooling. The most popular theory is that our planet was originally a molten mass drawn off from the sun by the attraction of a passing star. As its outer portion cooled, a crust formed. This cooling crust contracted, and the thermal pressures of the gases and boiling mass within shattered the thin shell. Boiling lava broke through, consuming the crust, but reducing the temperature of the molten mass so that the surface of the globe could once more solidify. After this had occurred numerous times, the heat of the melted rock was sufficiently reduced for the relatively hard shell to form.

While the Earth was still almost as hot as flowing lava, heated gases condensed into water to fill pockets. Perhaps this water was turned to liquid vapour many times during the cooling of the Earth. Eventually, however, the crust hardened and held the water in the permanent basins, which eventually gave rise to the oceans.[1]

#### Ocean zones

The ocean can be divided from its surface to its depth into three zones based on the amount of light received. They are:

- The sunlit zone: This top layer nearest the surface also called the euphotic zone is about 180 metres deep. In this zone, there is enough light penetrating the water to support photosynthesis, which accounts for the fact that more than 90 per cent of all marine life lives here. The sunlit zone is the habitat of most fish and plankton, microscopic organisms that form the basis of the food chain in the ocean.
- The twilight zone: Also known as the disphotic zone, this is a murky part of the ocean beginning at about 180 metres and extending to some 900 metres. Only a small amount of light can penetrate the water at this depth. As the water becomes deeper, the pressure increases. Plants do not grow here and only those animals that have adapted to little light can survive in this zone. These animals include lantern fish, rattalk fish, hatchet fish, viperfish, and mid-water jellyfish. This zone is also home to some squid and fish that can use their bodies to make light (bioluminescence).
- The midnight or aphotic zone: Ninety per cent of the ocean lies in this entirely dark zone where the pressure is extreme and the temperature near freezing. The living things found here are found close to cracks in the Earth's crust, which emit mineral-rich materials. Special forms of bacteria utilize hydrogen sulphide from the cracks for energy to make food. These bacteria nourish all other living things in the midnight zone. Animals in the midnight zone include anglerfish, tripod fish, sea cucumber, snipe eel, opposom shrimp, black swallower and vampire squid.

The oceans may also be viewed as having both a horizontal and vertical dimension. The vertical dimension is the water column. The horizontal dimension has two aspects: the high seas and the coastal margin, a complex system where land, sea, freshwater and atmosphere interact. Coastal ocean waters are characterized by a high degree of variability in biochemical and biological properties.

The marine microlayer (the boundary between ocean water and the atmosphere) is responsible for biological, chemical and physical processes that affect nutrient distribution in ocean water, the uptake of greenhouse gases from the atmosphere and the exchange processes for provision of oxygen to marine organisms. The marine

microlayer is destructively affected by oil released through slick formation.

Oceans may be considered giant heat ponds collecting and storing solar energy in a warm subsurface layer beneath the marine microlayer. This subsurface layer varies in depth depending on geographic location, currents and other physical factors but rarely exceeds 20 metres. Because of its nature, this layer supports many species and humans favour it for recreational activities.

The thermocline is the layer separating the surface layer from deeper waters marking a temperature drop of 5 °C or more. Marine plants useful to mariculture have their roots in deeper, cooler waters.

The abyssal depth is the lowest part of the ocean, with temperatures between 40 °C and 60 °C. It is rich in nutrients and virtually free of pathogens. A profusion of life forms, known as extremophiles, inhabit this region, and they have evolved unique mechanisms to survive in their inhospitable environment. They reside near the numerous hydrothermal vents that break through the seabed and release heat from the Earth's inner core.

### Marine life

The oceans provide a safe haven for biologically diverse life forms ranging from the smallest known, the virus, to the largest, the blue whale. Marine animals may be divided into those that are warm blooded and those that are cold blooded. All the marine air-breathing mammals such as whales, porpoises, dolphins, seals, walruses, etc., belong to the warm-blooded class. Tropical and subtropical marine waters support a greater diversity of life than colder waters.

The least developed countries possess the most potentially valuable marine resources since most of the tropical waters are situated within the territories of the developing nations. Animal life on the surface depends on oxygen for energy and carbon as a building material.

In the abyssal depths, animals thrive on the methane-sulphide- and hydrogen-sulphide-rich waters produced by the hydrothermal vents. An interesting survival mechanism is the unique symbiosis between micro-organisms, clams, and mussels (tube worms).

### Ocean farming

The oceans cover about 71 per cent of the Earth's surface and thus receive more than twice the solar energy received by the land. This would lead us to conclude that the oceans' potential productivity greatly exceeds that of land. Ocean areas considered fertile are found where runoff from the land or the upwelling of nutrient rich deep water fertilizes the surface water. This stimulates growth of marine plants, photosynthetic organisms on which all other marine life depends. Instead of devising efficient fishing means, man needs to learn to develop the potential of oceans by farming them. Oyster farming is one of the earliest types of marine farming.

### Ocean resources

The history of exploitation of the interface of the floor of the ocean with the overlying water spans the relatively short period of approximately 120 years. This is related to the remoteness of the deep sea and the resulting difficulties in studying this environment: the methods of study are restricted by the need for instrumentation and observation chambers to be encapsulated in the atmosphere of the surface, and strengthened against the crushing pressure of a water column several kilometres high.

In the mid-nineteenth century, investigations for life on the bottom of oceans were conducted by Norwegian pastor/naturalist Michael Sars, who listed nearly 100 species of invertebrate living at depths greater than 600 metres, and British explorer John Ross, who discovered the many-armed basket star. On the basis of these explorations, Irish naturalist Wyville Thomson was convinced that life could be found at the ocean's greatest depths. Thomson's work laid the foundation for our present knowledge of the life of the deep sea floor and represented a quantum leap for the infant science of oceanography.[2]

### EARLY FISHING AND OCEAN FARMING PRACTICES

Ocean farming is not new to the world. Many countries have been interested in this area for a long time and have developed various techniques of harvesting ocean products. Some of the regions with a long ocean farming history are discussed below.

### Aquaculture in China

Freshwater fish culture in China has been recorded for over 3,100 years. Mariculture of certain molluscs existed some 1,700 to 2,000 years ago. Modern aquaculture started in the early 1950s as a result of technological advances and organized government efforts, and the Chinese aquaculture industry grew steadily between the 1950s and late 1970s, and major advances in hatchery production technology were made during that period. However these technical advances did not lead to rapid increases in production in China for social and economic reasons. Starting in 1978, China began implementing a series of economic policy changes, gradually replacing central planning with a market economy. As a result, the Chinese aquaculture industry began its rapid expansion in the early 1980s.

The most important species are silver carp, grass carp, common carp, bream and black carp. Chinese carps are mainly farmed in polyculture systems in earthen ponds. In a typical polyculture system, carps with different feeding requirements are stocked together at certain ratios to fully utilize food resources in the system. As their name indicates, grass carps are herbivores and fed with grass. Solid waste from grass carps supports phytoplankton and zooplankton blooms, which are utilized by filter feeders such as silver and bighead carps. The Chinese also raise high-value species such as the river crab, shrimp, crawfish, eel, trout, frogs, and turtles.

Molluscan culture in China started to expand beyond the four traditional species in the 1970s. Mussel culture was the first new industry to emerge, followed by scallop and abalone aquaculture in the 1980s. Shrimp culture has been a major cash industry since the 1980s, and has greatly benefited many coastal regions. Major advances in marine fish culture occurred in the 1990s.

Seaweed culture, which is now a major mariculture industry, was developed in the 1950s as a result of breakthroughs in breeding technology. Hatchery-produced seaweed seedlings are set on rope and cultured on suspended long lines, which are also used for the culture of kelp, scallops, abalone, mussel and oysters. In China, these long lines often cover most of the bays or stretch for large distances along the coast.

Flounder, sea bream, mullet, and puffer fish are some of the marine fish cultured in China. Land-based intensive systems and floating net cages are common, and large shrimp ponds are also used for fish culture.

## History of whaling

Whaling started in the first few centuries of the first millennium BC by the Japanese, and between about 800 and 1000 AD by the Norwegians and by the Basque people living in France and Spain. The Dutch, British and Americans developed whaling in the seventeenth century.

Whaling involved approaching a whale in small boats and driving flint-tipped spears attached to sealskin floats into the animal. Each time the whale rose to blow, more spears were driven into its body until it was so exhausted by the struggle to force its body down against the buoyant drag of many floats that it ceased submerging. Remaining on the surface, the weakened whale could be killed more easily.[3]

Entire canoe fleets of Pacific Coast Indians hunted by driving many spears into the whale when it came up for air. When the assaulted whale finally died, it sank, but within a day or so, the gases emitted from the decomposition process would cause the carcass to float to the surface, at which point it could be towed ashore.

Most of the whalers hunted the slow and docile northern right whale. The whales were sought for their oil and baleen (whalebone). The Japanese ate the meat and found uses for many other parts of the whale. A species related to the right and bowhead whale was hunted to extinction in the Atlantic Ocean.

The American whalers also hunted the sperm whale, first in the Atlantic from New England ports and later in the Pacific from bases in Hawaii. Sperm whales feed on giant squid deep in the ocean, including species that have never been seen alive.

The baleen whale known as the California grey whale was hunted in the lagoons of Baja California, where they breed, and from 16 shore stations along the California coast. It sucks mud from the ocean bottom through one side of the mouth and filters crustaceans called amphipods from the mud using short baleen plates. Hunted to near extinction in the late 1800s, the California grey whale recovered only to once again be threatened with extinction in the 1930s and 1940s by factory ships. Today the species is up to pre-exploitation levels (about 26,000) and has been removed from the endangered species list (Plate 86).

## Development of ground fishing in New England

For over 400 years, the New England fishing industry has been associated both economically and culturally with ground fishing for such bottom-dwelling species as cod, haddock, redfish and flounder.[4]

The Industrial Revolution caught up with the fishing industry around the beginning of the twentieth century. The introduction of the steam-powered trawler from England heralded a major change in the way ground fish were caught, and rapidly replaced the schooner fleets. At the time, there was concern that the powerful new technology would threaten the productivity of the stocks. Scientific investigations of the time warned that the new technology should be applied with care.

By 1930, the fleet had grown too efficient in relation to the stocks' capacity to sustain growth. A new round of scientific investigation begun in 1930 at Harvard University revealed the consequences of the new technology.

Prior to the Second World War, the fleet was large, but profitability was low. Consumption of fish in America had nose-dived as the descendants of immigrants abandoned Old World traditions of fish consumption. With the outbreak of war, the fleet was further reduced as many of the largest trawlers were requisitioned for war duty as mine sweepers. When these vessels returned from war, the industry continued to suffer owing to a continued reduced demand for seafood. Fortunately, the development of new marketing strategies, such as selling ocean perch in the Midwest as a substitute for Great Lakes yellow perch, sustained the offshore fleet.

The beginning of the 1960s saw the development of the most serious threat yet to the sustainability of the fishery. Ocean-going fish factories of the distant water fleets began depleting the cod, haddock, hake and herring resources of the once-rich Georges Bank fishing ground extending from New England to Newfoundland. Soon fleets from East Germany, Poland, Spain, Japan and others joined those from the Soviet Union. Not until the early 1970s could an international commission settle on fishing restrictions, too late to avoid the virtual collapse of most ground fish stocks. There was much pressure particularly from the fishing industry to establish American jurisdiction over a 320 km fishing limit. Congress enacted the Magnuson Act of 1976, taking control of the Exclusive Economic Zone (EEZ) and setting up a system of regulation of the domestic industry. Fuelled by great expectations and aided by subsidy programmes in place since the 1950s, the United States began to build new, modern fishing boats. The fleet, once dominated by wooden side-trawlers, was quickly replaced with steel stern-trawlers, miniature versions of the factory trawlers used by the distant water fleets.

Now the cry for regulation comes not just from the fishermen, but also from environmental groups, the general public and elected officials. Years of supporting industry growth have left the federal government vulnerable to charges that its policies helped collapse the fish stocks and harmed the environment.

## Period synopses

Following the New England example, the history of twentieth-century ground fishing can be divided into six time periods, based on a combination of factors including technological development, changes in species abundance, development of markets for new species, or improved marketing of existing fishes, and major changes in the regulatory regime. Some of these factors relate to more than one time period, whereas others were isolated events

that so greatly dominated the scene that they clearly marked new eras.

### 1. Sail to steam (1900–1920)

Prior to the introduction of steam trawling in 1906, ground fish were caught exclusively with baited lines, fished from schooners and their dories. Owing to the length of their journeys and the lack of refrigeration and freezing, most of the cod catch was salted at sea.

### 2. Cod to haddock (1920–1930)

Along with the transition from schooners to trawlers, the targets of the fishery changed as well. Developments in cold storage, marketing and distribution allowed fresh fish to be available in areas far from the fishing ports. Rather than salt cod, the industry switched to haddock. Landings of haddock shot up rapidly as demand grew. This period witnessed the development of the fresh fish industry and the consequences of the shift in target species to the utilization of the ground fish resource.

### 3. Fishing troubles (1930–1960)

The sudden rise in popularity of haddock resulted in early signs of stress in the stocks, and landings plummeted. Scientists were asked to study causes of the drop in landings and to recommend conservation measures. Biologists of the period recommended increasing net mesh sizes. Profitability of the fishing industry declined significantly through the Great Depression. The outbreak of the Second World War resulted in prosperity as wartime protein demands increased, while there was a shortage of large fishing vessels owing to the conscription of a large part of the fleet for military activities. After the war, lower demand and more vessels resulted in very low profitability.

### 4. Distant water fleets (1960–1976)

The presence of distant water fleets was universally denounced by the domestic industry, especially off the coast of the United States. The industry supported research showing the harmful effects of over-exploitation. At this time, both the American and Canadian fishing industries and scientists were united against the non-North American factions to protect local interests. But the Magnuson Act contained provisions more sweeping than just curtailing international fishing; it also stipulated for the first time that United States fisheries would be managed for maximum benefits to society.

### 5. The Second Industrial Revolution (1977–1984)

Following the passage of the Magnuson Act, there was great optimism in the fishing industry. New modern vessels were constructed, some using financing available at low rates through existing government loan programmes. The Canadians also had extended their territorial jurisdiction 320 km seaward, excluding United States vessels, which had fished off the Scotian Shelf and the southern Grand Banks for generations. In 1979, a draft treaty on reciprocal fishing rights was agreed to at the ministerial level. The treaty recognized historical fisheries by the United States off Canada, and vice versa. However, with the change in administration in 1980, and opposition from some sections of the industry, the draft treaty was not approved.

## FISHING AND MARICULTURE PRACTICES

Salmon aquaculture is now undertaken in two main ways: freshwater rearing and sea-cage rearing.[5] Both methods involve first collecting eggs and milt from captive brood stock, incubating the fertilized eggs in a freshwater hatchery (usually at 10–12 °C), and rearing the newly hatched fry for an additional 6–12 months. In freshwater and sea-cage operations, the young fish (or smolt) are then transferred to larger cages or ponds, where they are reared for the remainder of their lives. Fish remain in captivity for two to three years, and are typically harvested at weights of between 2 and 4 kg.

In ocean ranching, large numbers of smolts are released to sea to fend for themselves before reaching adulthood, then rely on their legendary homing ability to guide them back to their point of release to be harvested. Many companies attempted this potentially efficient style of farming during the 1980s, but abandoned it when marine survival rates proved too low and inconsistent to sustain a commercially viable return.

### Handlining and jigging

Handlining and jigging are two of the oldest forms of fishing and are still common;[6] indeed, single-line methods are still used by many inshore fishermen on the Atlantic Coast. Handlining utilizes a line to which a weight and baited hook is attached. Jigging operations involve the use of lure-like hooks attached to a line, which is 'jigged', or moved up and down in a series of short movements in the water at a level where fish are present. The motion attracts the fish, which are hooked as they go for the lure. The line is then hauled onboard and the fish removed. Handlining and jigging are mainly used to catch ground fish, although pelagic organisms and other species are sometimes caught.

Jigging machines have recently become widely used for catching ground fish and squid. These machines work on the same principle as jigging by hand but are made less labour intensive by the use of electric or hydraulic motors, which automatically move the line up and down in a jigging motion and retrieve the line when fish are hooked.

### Longlining

Longlining, as the name implies, involves the use of a 'longline' with a series of baited hooks spread along the ocean floor. Initially practised manually, this method has now become mechanized and uses automatic hauling, baiting and shooting machines. These improvements have made longlining an increasingly popular form of fishing, for it enables fishermen be more selective, yields a higher quality of fish, and also require less fuel. Longlining is practised primarily in the Atlantic provinces to catch ground fish such as hake, haddock and halibut.

## Bluefin tuna fishing

Bluefin tuna are caught in both commercial and sport fisheries. Bluefins are primarily a by-catch for fishermen engaged in operations such as mackerel trapping. When captured alive, the tuna are placed in corral-like pens and fed mackerel and other fish until a desired weight and fat content is reached, in preparation for sale. Fishing for bluefins is also conducted in big-game style, employing rod and reel manipulated by a fisherman strapped to a chair fixed to the rear deck. Fishing line of breaking strength no greater than 60 kg is required.

## Gillnetting

Gillnets are used on the Atlantic coast to catch many species of fish, especially ground fish and pelagic organisms and such anadromous species as salmon, smelt and gaspereau. They are principally made of monofilament netting and may be either secured to the bottom of the sea with the use of weights or left to drift. Fish are caught as they attempt to swim through the webbing, entangling their gills. Nets are anchored to the seabed to keep the gear stationary and the buoys that float on each end indicate the location, the owner of the gear, and provide a line from which the gear can be raised to the surface to harvest the catch. The nets may be positioned in varying depths, depending on the location of the species. It is common for fishermen to attach a number of nets to increase the efficiency of the operation. The size of the mesh used in gillnets differs depending on the species and size of the fish sought.

## Weir fishing

The weir method of fishing is used in the Bay of Fundy, where the extraordinary height of the tides prevents the use of other types of traps. Weirs are also used on both sides of the St Lawrence River in Quebec. Rigid poles are driven into the mud bottom in a heart-shaped configuration. A straight line of poles is then placed from the shoreline to the weir. This line acts as a barrier to the fish, which follow it into the weir. Once inside, they become disoriented and swim in circles.

## Cod traps

Practised primarily in Newfoundland, cod trap fishing is similar to weir fishing. The traps resemble open-topped box nets, with a perimeter of 11–22 metres and a vertical opening or 'door' on one side. The trap is set on the ocean bottom, usually close to the shore, with the door facing shallow water. It is buoyed on the top and anchored on each corner to maintain its position. A long net fence or 'leader' extends from shallow water into the mouth of the trap. When the cod, feeding on fish such as capelin along the seashore, confront the leader, they instinctively shift direction, swimming through the open doors into the trap. Once inside, they tend to swim in circles, trying to avoid the leader, and so fail to locate the doors.

## Offshore lobster traps

Offshore lobster traps are constructed of metal or heavy wooden frames covered with wire mesh, and are considerably larger and sturdier than inshore traps. Vessels of the offshore fleet measure between 18 and 34 metres in length and are based in southwestern Nova Scotia. These offshore vessels are not permitted to harvest lobster closer than 80 kilometres from shore.

## Inshore lobster fishing

Inshore lobster fishing is practised by inshore fishermen using traps set on the ocean floor, either individually or in groups on a line. The size and design of these traps differ somewhat in various localities, but they are usually constructed of curved pieces of wood, laths, and cotton or nylon twine, and often weigh in excess of 40 kg. Every trap has one or more funnel-shaped openings fashioned from twine, which allow the lobster to enter the trap but prevent it from escaping. They are baited with either fresh or salted fish, commonly herring, and mackerel. Traps are set in waters of varying depths, but usually near the rocky bottoms preferred by lobsters. In recent years, fishermen have begun to make greater use of electronic equipment to determine water depth and bottom type. Traps are ballasted with flat stones or concrete slabs to sink them and reduce their movement on the ocean floor. Marked buoys allow the gear to be easily located and identified. The traps are hauled up on the boats using winches. Smaller, illegal-sized lobsters are returned to the water along with any unwanted species. The harvested lobsters are kept alive in boxes or tanks containing circulating water.

## Crab traps

Crab traps differ considerably from those used in the lobster fishery. They are framed with iron rods, covered with polyethylene rope webbing and may be either cone-shaped or rectangular. Crab traps are much more expensive than lobster traps because of the material used, and are somewhat larger. Usually only one trap is placed on each line. While the main species caught in the Atlantic area is the snow crab, exploratory fishing is being conducted for rock crab, Jonah crab and red crab.

## Purse seining

A seine is a wall of webbing used to encircle fish. Its effectiveness in catching fish results from its encircling action, rather than towing. As with the gillnet, the purse seine has floats on the top and weights on the bottom to maintain its vertical position in the water. A purse seine, however, has a wire rope passing through rings on the bottom of the net, thereby enabling the net to be drawn together to entrap fish. While purse seines are used to catch many species of fish, they are most effective when used to capture fish schooling near the ocean bottom. When a school of fish is detected, one end of the seine is taken by a small boat or 'skiff'. The vessel and skiff then encircle the fish with the net. After receiving the end of the line from the

skiff, the vessel begins to winch in the wire cable, closing the bottom of the seine and forming a bag-like net around the fish. The other lines are then also winched in, reducing the space inside the net, which is then brought alongside the vessel. The fish are dipped out and put in penned-off sections, boxes, or in the hold of the vessel.

### Eel traps

The principal commercial device used to harvest eels is the flume or 'hoop net.' The name comes from the hoop used to frame the net. The hoops are set in rivers, trapping the eels as they move in. A leader set in front of the net directs the eels into the funnel-shaped sections of the trap, from which they cannot easily escape.

### Canadian pair

Canadian pair seining is a recently developed method of fishing used by relatively few fishermen. Two vessels sweep an area of smooth seabed with cables and ropes, corralling fish into a net, and winching the net in. The net resembles an otter trawl net with a much wider vertical opening. It is set and hauled by the two vessels, which maintain coordinated positions through regular radio contact. The success of the operation relies on the 'heading' effect of the 'warps' or cables. When the vessels come together, the cables are brought together, and the net is winched in from both boats.

### Otter trawling

Otter trawls are cone-shaped nets towed along the ocean bottom to catch many species of ground fish. They take their name from the rectangular doors, or 'otterboards', attached to cables between the boat and the net. These doors keep the mouth of the net open horizontally while the net is making its tow. A vertical opening is maintained by the combined effect of the weights on the bottom, the floats on the top and the water pressure generated from the towing. The net traps fish in the end of the bag-like section or 'cod-end', which has a mesh size that permits only the smaller fish to escape. The net rolls along close to the bottom with the aid of bobbins, which are similar in appearance to wheels. After a period of towing, the trawl is winched up beside the vessel. In a side trawling operation, the cod-end is raised and suspended over the vessel. The cod-end is untied, and the catch released onto the vessel's deck, where the fish are bled, gutted and stored in the hold. In a stern trawling operation, the gear is hauled up the 'stern ramp' and the cod-end opened.

### Mid-water trawling

Mid-water trawls can be used to catch many species of fish, most commonly herring, mackerel, redfish, pollock, capeline and shrimp. Mid-water trawls resemble otter trawls in that they are cone-shaped and constructed of webbing. Unlike otter trawls, however, they have fewer weights, and thus can be adjusted for towing at various depths. This adjustment is made by increasing the vessel's speed or by varying the length of the cable or 'warp' between the vessel and the net.

### Atlantic side trawling

Atlantic side trawlers belong to the older series of ground fish trawlers, which are declining in numbers due to the preference for more modern stern trawlers. They are referred to as side trawlers since the gear (trawl) is towed from gallows attached to one side of the vessel.

### Stern trawling

Stern trawlers are the main components of Canada's Atlantic offshore fishing fleet and are modern vessels of steel construction, averaging in size from 30–50 m. Atlantic stern trawlers harvest traditional ground fish species such as cod, haddock, flounder and hake. The gear (trawl) is hauled into the vessel over a large ramp through an opening at the back or 'stern' of the ship. Stern trawlers can operate in almost any waters or weather conditions and often range as far as 450 km off the Canadian east coast, fishing at depths of up to 100 m. These vessels can contain up to 2.7 tonnes of fish within their holds. They carry a crew of about 15 and can fish for 10 days to two weeks each trip.

### Oyster tonging

Tonging is the main method used to harvest oysters. It is used on natural oyster beds and small leased areas where regulations prevent the use of other equipment. Tongs consist of a pair of rakes attached to long, wooden scissor-like handles. The handles are joined together approximately one-third of the way from the end of the rakes. The teeth of the rakes point inward, and some tongs have baskets attached on both ends. The handles vary from three to eight metres in length. With a series of short lifting movements, the oysters are scraped off the bottom and gathered up into the boat. The vessels used in the operation are usually small because of their versatility. Harvesting oysters with tongs is a very time-consuming operation because tongs can be used only when the water is calm, and tongs are inefficient in water over five meters deep.

One of the new scientific methods applied to mariculture to increase production is marine biotechnology.[7] This term encompasses any scientific investigation that focuses on marine organisms and utilizes new cell, protein and nucleic acid technologies such as recombinant DNA (rDNA), protein engineering, DNA hybridization, etc. Biotechnology techniques are included under the rubric of marine biotechnology if they are used in certain applied fields like aquaculture, fisheries and natural marine products.

### EFFECTS OF OCEAN FISHING AND MARICULTURE ON THE ENVIRONMENT

Mariculture has two effects on the coastal environment:[8] some types of mariculture improve the coastal environment and increase food supply, while others deplete wild fisheries

stocks and damage the coastal environment. According to the driving factors of systems, aquaculture ecosystems can be divided into two groups: autotrophic or natural trophic systems such as kelp culture systems and raft culture systems for scallops, which obtain energy from solar radiation and nutrients from water; and heterotrophic or artificial trophic systems, such as net culture systems for feeding fish and pond culture systems for shrimp, which obtain energy mainly from artificial feeds. There are many features of ecological mutual compensation between the two types of aquaculture systems. For example, in China, most mariculture production is produced from autotrophic systems. However, we should not neglect the negative effects of some types of mariculture on the coastal environment in our aim to achieve sustainable mariculture. Some of these are as follows.

## The spread of antibiotics

Antibiotics and other therapeutic chemicals added to feeds can affect organisms for which they were not intended when the drugs are released as the uneaten pellets decompose.[9] Nonetheless, many drugs used in fish farms have been found to have minimal (if any) deleterious effects on the aquatic environment. Feed additives, however, are not the only source of potentially toxic compounds in culture operations. A variety of chemicals are used to inhibit the growth of organisms.

## The aquaculture effluent: pollution of inland and coastal waters

Although a link between fish farming and the decline of natural stocks cannot always be established, some environmental effects are clear. Unlike mollusc farming, many species of fish depend on a diet of artificial feed in pellet form. This feed is spread onto the surface of the water and consumed by the fish as it settles through the water column. Because not all the feed is eaten, a great deal of feed can reach the bottom where it is decomposed by micro-organisms. This alteration of the natural food web structure can significantly impact the local environment.

## Eutrophication

An increasingly significant effect of intensive fish culture is eutrophication (increase of mineral and organic nutrients in a water body, thus reducing dissolved oxygen and producing an environment that favours plants over animals) of the water surrounding rearing pens or the rivers receiving aquaculture effluent. Fish excretion and faecal wastes combine with nutrients released from the breakdown of excess feed to raise nutrient levels well above normal, creating an ideal environment for the formation of algal blooms. To compound the problem, most feed is formulated to contain more nutrients than necessary for most applications. In Scotland, for example, an estimated 50,000 tonnes of untreated and contaminated waste generated from cage salmon farming goes directly into the sea, equivalent to the sewage waste of a population of up to three-quarters of Scotland's population. Once the resulting algal blooms die, they settle to the bottom where their decomposition depletes the oxygen. Before they die, however, there is the possibility that algal toxins are produced.

## The effect of intensive fish rearing

The method of intensive fish rearing in dense, cage farms in protected marine areas has an environmental price attached. Uneaten fish food, together with the fish excretions, may accumulate on the seafloor under the cages, in conditions of low water exchange. This accumulation may have a negative effect on the marine environment. The organic matter, as it accumulates, may undergo biochemical and microbial changes. High levels of hydrogen sulphide may be produced in the marine substrates, followed by deterioration in the oxygen level of this environment. These changes can cause the death of immovable organisms and repel mobile forms of life from the damaged habitat.

## The effect of sedimentation

The structures used during cultivation processes can cause environmental change.[10] For example, the use of netting to protect clams from crab predators leads to siltation and accumulation of sediment. Parks of trestles can drastically alter the water flow regime leading to changes in sedimentation rate and oxygen exchange within the system. Extensive intertidal cultivation plots could deprive birds of feeding habitats, and the associated husbandry practices may disturb roosting birds.

The final stage of cultivation involves harvesting. In many cases, this entails little more than emptying the bivalves from lifting ropes. However, in the case of species cultivated within sediment, or relayed on the seabed, the use of intrusive techniques is required. Both dredgers and suction devices cause disruption of the sediment and kill or directly remove non-target species.

## Marine animal health

Bacterial, fungal, protozoan and viral infectious diseases are widespread among natural fish populations. Animals raised in aquaculture are especially vulnerable to damage by disease. Polluted waters favour the development of fungal diseases, the most common agent being *Saprolegnia*. There are also positive aspects to coastal shellfish cultivation, such as the provision of hard substrata and shelter in otherwise barren sites and the possibilities of using the cultured organisms as environmental sentinels or guards.

## CONCLUSION

Our knowledge of the oceans has been progressively enriched by the development of oceanographic research during the last century. The potential of mariculture has been mapped out and characterized by modern techniques. Scientific and technical methods, which may vary according to the region, have been developed and applied to harness and exploit marine culture commercially. Humankind now

realizes that the ocean is a source of food if properly maintained and utilized. Fish farming has yet to reach its maximum potential. Large areas of our planet remain to be developed into highly productive marine farms. However, advances in the technological exploitation of mariculture generate threats to the environment, and we must work to combat them.

# ELECTRONICS

*Eriabu Lugujjo*

## THE ELECTRONIC AGE – EARLY RESEARCH AND DEVELOPMENT

By the turn of the last century, it was known that electrons existed and that many metals would emit electrons if exposed to radiation. However, no electron device based on this phenomenon existed. The Fleming Diode, introduced in 1904, is usually considered to be the prototype electron device. This diode had two electrodes – one a thin filament of wire (the cathode) and the other a metal plate (the anode). The cathode could be heated by an electric current and the electrodes were enclosed in an evacuated glass envelope. The diode acted as an electrical conductor when the anode was kept at a positive potential with respect to the cathode. Upon radiation the electrons emitted by the cathode were captured by the positive anode, thus forming a current flow. When the polarity was reversed, there was no current flow and the diode acted as an insulator. This non-linear behaviour was eventually exploited in the development and perfection of other electron devices.

In 1906 and 1907, De Forest invented what is now called a 'triode'. He put a third electrode in the form of a wire grid between the cathode and anode of the diode. In this arrangement of three electrodes, the current flowing to any electrode depends on the potential of all three electrodes. It is interesting to note also that under certain circumstances the grid potential acts as an effective control of the current to the anode without taking much itself. The triode thus became a practical way of transmitting radio waves and contributed significantly to the growth of radio broadcasting.

After the discovery of the triode, other multi-electrode valves with four, five and more electrodes were introduced. Of course, these new electrodes gave additional advantages of various kinds. However, their operation depended on their non-linearity or the amplifying property of the grid. It should be emphasized that diodes worked under space-charge conditions

At high temperatures the rate of emission of electrons from the cathode is so large that the potential in the vicinity of the cathode is lower than that of the cathode. For an electron to reach the positive electrode (anode), it must

have energy in electron volts greater than the amount of the potential depression. What this means in practice is that electrons emitted from the cathode have a distribution of velocities. Electrons with insufficient energy to surmount the potential barrier are returned to the cathode. As the temperature increases the emitted number of electrons increases – and a negative potential region surrounds the cathode. More electrons are repelled by this negative region. At higher temperatures, the fraction of electrons overcoming the potential barrier decreases in such a way that the net current reaching the anode does not change appreciably. Operation under these conditions is classified as space-charge-limited. Indeed diodes are operated in this region.

After triodes, other multi-electrode devices were discovered, such as tetrodes. The tetrode was improved by addition of a third or suppressor grid between the screen grid and the anode. The resulting five-electrode tube was named the pentode.

From roughly 1907 to 1912, radiotelephony developed slowly in Europe. However in 1915, the engineers of the American Telephone and Telegraph Company succeeded in talking by radio from the huge naval station at Arlington, Virginia, to Paris (France) and, in the opposite direction, to Honolulu. This great experimental feat was accomplished by using vacuum tubes as oscillators and voice amplifiers.

The years 1921–23 marked the beginning and organization of broadcast radiotelephone, a service for subscribers to listen to scheduled programmes of music, lectures, news bulletins, educational and entertainment content.

By the 1920s, diodes were already operating in X-ray tubes and for rectification purposes. Indeed there were triodes for amplification, oscillation, switching and counting. Multi-electrode tubes were developed for the same uses above, but in a more refined form.

Other types of vacuum valves that work on the principle of secondary emission were developed. These included electron multipliers and photo-multipliers. Photo-multipliers working on the principle of photoemission were discovered and used for measuring and amplifying light. Then followed photocells, which are still used for light

measurement and control. The emission of electrons from the cathode requires additional energy. In thermionic emission – the emission of electrons into a vacuum – extra energy is given to the electrons by heating the cathode. Energy may also be supplied as radiation, when photoemission occurs. Finally, the electrons may be knocked out of the cathode by impact with other fast electrons or ions. This is called *secondary emission*.

Another important development was the introduction of gas tubes. In this case conduction electrons are produced by using radiation or fast particles to ionize gas atoms. These tubes include diodes, triodes and tetrodes. An example of such devices is the thyratron. This is a gas-filled triode with a thermionically heated cathode. The period 1920–30 saw the development of devices that control the movement of electron beams between electrodes with both steady and alternative fields. Klystrons and magnetrons were developed on this principle. These are special valves used at the higher frequencies. The klystron is very useful in the conversion of direct current (DC) to alternating current (AC). Magnetrons are vacuum-tube devices that generate or amplify high-frequency electromagnetic waves.

The years 1920–30 also marked the beginning of quantum mechanics, for which numerous important applications were found in other areas in the years to come. By 1927 the basic concepts of the new quantum theory had been ironed out, thus providing physicists of the time with powerful tools to describe electronic and atomic systems and to explain the cohesion of atoms in solid crystals.

By 1931, Wilson had developed a theoretical model of quantum mechanics that related what had been learned about the motion of electrons in metals and also provided a fair explanation of insulators and semiconductors. The 1931 publication of Wilson's theoretical model of solid-state semiconductors coincided with an increasing interest in semiconductors for use in electrical communications. Indeed, tubes had been in circulation and upgraded over the years. However they were not useful for the short wavelengths being studied in the 1930s, and thus the rectifying properties (converting an alternating current into a direct current) of semiconductors attracted great attention. One drawback was that the implications of Wilson's theory were not very clear to the research workers of the time, as it had been described in wave-mechanical terms.

It was not easy to perform any experiments on semiconductors. For example, there had been uncertainty whether the non-ohmic behaviour of a contact between a metal and a semiconductor was a property of the semiconductor alone – a 'volume property' – or of the contact between it and the metal – a 'surface property'. It was a real brain teaser for anybody to examine experimentally the electrical properties of a semiconductor without making contact with it. Fortunately, by 1935, a series of experiments had made it clear that the non-ohmic property belongs to the contact, not to the semiconductor itself.

When research on such questions reappeared after the war (1945), it was directed at an understanding of silicon and its neighbour germanium. Silicon and germanium are single chemical elements, falling successively below carbon in Group IV of the periodic table. They crystallize with a simple atomic arrangement. The atoms in these crystals are bound together by pure covalent bonds. Silicon and germanium are indeed prototypes – 'ideal' semiconductors. Their conductivities are intermediate between those of insulators and metals. However their conductivity is electronic, like that of metals.

## THE TRANSISTOR REVOLUTION AND ITS OFF-SHOOTS

In the late 1930s, a young physicist at Bell Laboratories named William B. Shockley became interested in the possibility of developing a solid-state device of some kind to provide an electronic substitute for electrochemical switches that were universally used in telephone exchanges to connect one telephone with another.[1] He and others believed that electronic telephone switching would eventually be needed and that vacuum tubes would probably be too costly and unreliable for the task.

Shockley saw promise in a theory that had been proposed by Walter Schottky in studies of rectification at the interface between a metal and a semiconductor. Shockley foresaw the possibility of an amplifying action in the region between the metal and the semiconductor. He believed that the region between the two structures (metal and semiconductor) would constitute a kind of valve action. In 1939, he tried building valve-like devices with a combination of copper oxide, but he was unsuccessful.

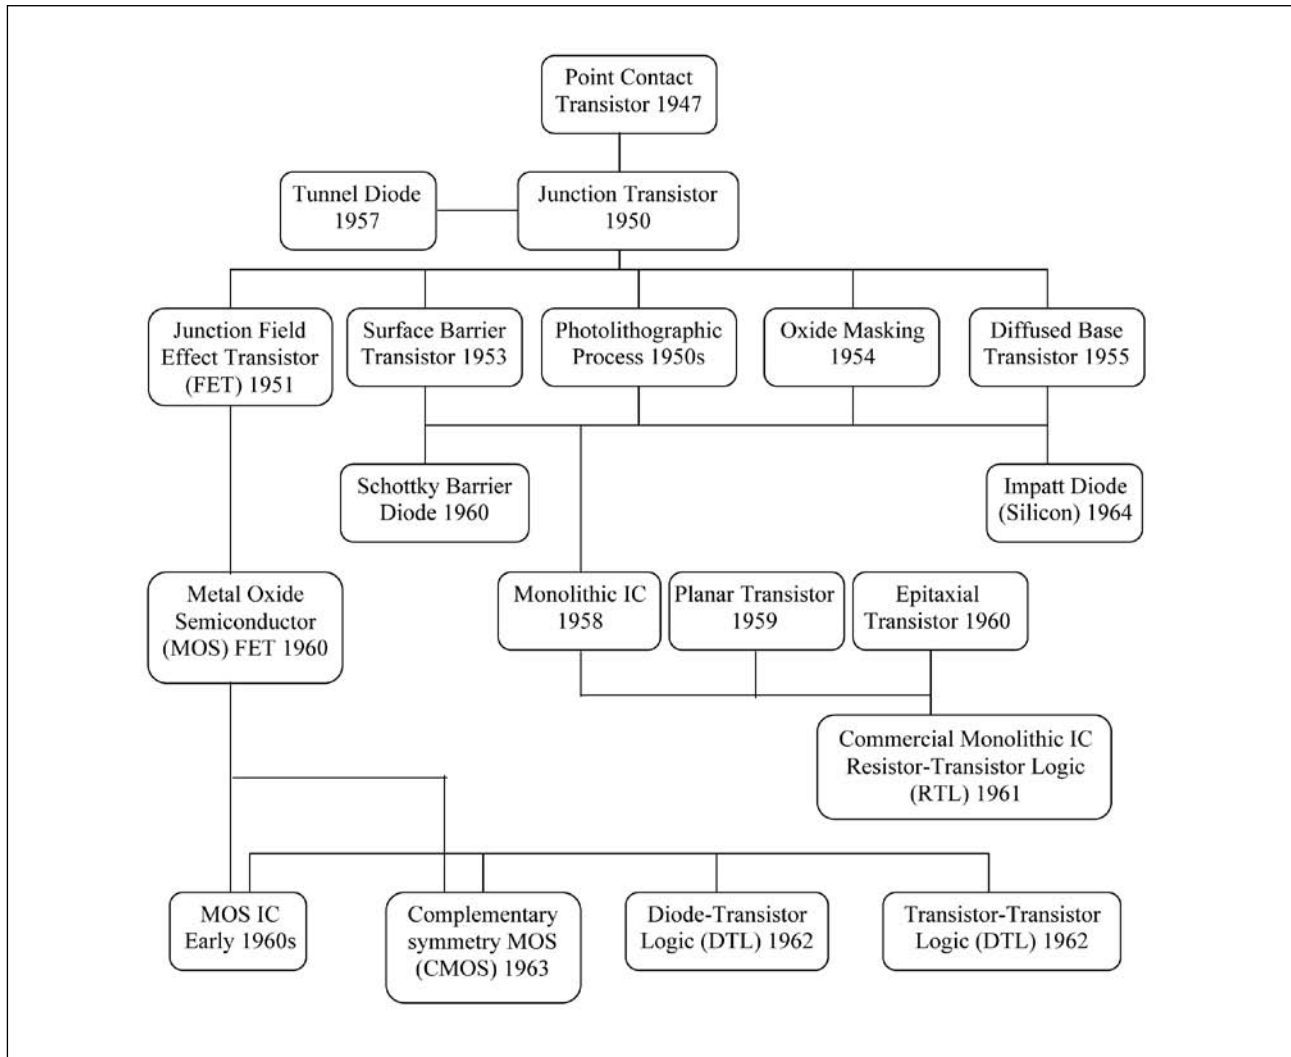
After the Second World War, Shockley returned to Bell Laboratories. He and Gerald L. Pearson observed field-effect behaviour in 1948 with the structure of silicon called p-n junction. In the same year, John Bardeen and Walter Brattain announced the development of a point-contact transistor. A year later William Shockley published a classic paper on junction diodes and transistors. The three scientists were awarded a Nobel Prize in 1956 for discovering the junction transistor. In 1952, Shockley published the theory of the field-effect transistors, and a practical form of the device was built by George C. Dacey and Ian M. Ross in 1953. This device used an electric field to control conduction in a germanium semiconductor structure.

In 1950, the first prototype of a junction transistor was constructed. The first practical alloy junction transistor that provided a more economical manufacturing process came on the market the following year, in 1951. The surface barrier transistor of 1953 pushed the frequency range into the MHz region. The diffused base transistor unveiled in 1955 provided outstanding high-frequency performance. The first monolithic integrated circuit was built in 1958 by Jack St. Clair Kilby, but it was not until 1961 that process and design advances made such circuits commercially viable.

### Electronics and solid-state engineering

With the advent of transistors and research on semiconductors, it seemed possible to imagine a solid electronic block with no connecting wire. The block had to consist of layers of insulating, conducting, rectifying and amplifying materials, the electrical functions being connected directly by cutting out areas from the various layers.

Figure 1 shows the transistor family and the first integrated transistor of Resistor-Transistor Logic (RTL) and Diode Transistor Logic (DTL).

*Figure 1* **Transistor family history**


The invention of transistors was a radically new departure in electronics. But before it could be universally accepted as the new basis for electronic circuitry, it was necessary to develop new circuit theories, new engineering and technical processes, and to establish new facilities for large-volume production. There was therefore a gradual acceptance and penetration of solid-state electronics in the market place and society at large.

In 1952, the junction transistor was four years old, the Korean War was at its height and both the military and large corporations were emphasizing the need for greater reliability from existing components. The United States Armed Forces was already considering what it loosely called miniaturization or even micro-miniaturization.

**Large-scale integration and miniaturization**

Large-scale integration, which entails combining thousands of circuit elements on a single chip, was prompted by various missile and satellite programmes that called for complex electronic systems to be installed in equipment in which

size, weight and power requirements were serious constraints. This revelation was timely because by the mid-1950s engineers had learned how to define the surface configuration of transistors by means of photolithography and developed the method of solid-state diffusion for introducing the impurities that create the p and n regions. In fact, by this time batch processing of many transistors on a thin piece of silicon and germanium (wafer) sliced from a large crystal of germanium/silicon had begun to displace the earlier technique of processing individual transistors.

In the integrated circuit, the separation and interconnection of transistors and other circuit elements is accomplished electrically rather than physically. The separation is achieved by introducing p-n diodes (rectifiers), which allow current to flow in only one direction. A conducting film of evaporated metal that is photoengraved to leave the appropriate pattern of connections interconnects the circuit elements. An insulating layer is required to separate the underlying semiconductor material from the metal film except where contact is desired. In 1958, researchers at Fairchild Semiconductors discovered the process that accomplishes this insulation when they

invented the planar transistor. In this transistor, a thin layer of silicon dioxide, which is the best insulator known, is formed on the surface of the wafer.

Large-scale integration, which is a basis for microelectronics, enables instruments not only to make measurements but also to analyse them. Over the past twenty years, complex and powerful measuring instruments and control devices have been designed and put on the market for the service of humankind. The use of microprocessor and digital technology has rapidly evolved and reading/testing errors have been minimized. Modern information processing and control systems call for the rapid storage and retrieval of digital information. The amount of information to be stored ranges from fewer than several hundred bits for a pocket calculator to a trillion bits for a large computer.

## ELECTRONICS AND SOME OF ITS DIVERSE APPLICATIONS

Early applications of electronics in the 1920s centred mainly on radio communications, rocketry, telephone, radar and the use of vacuum tubes in research and utility instruments. At that time, components were discrete in nature. Today, with the advent of solid-state electronics and miniaturization, electronics has become a 'global culture' that has permeated every sector of our society.

Developed countries are increasingly spending heavily on semiconductor electronics. Fields enjoying hefty budgets include computers, consumer electronics, solid state, communications, power generation, industrial electronics, military and aerospace, medical diagnostics, railroads, industrial electronics, and basic research. Table 6 illustrates

*Table 6* **Five generations of computers**

| Generation | First | Second | Third | Fourth | Fifth |
|---|---|---|---|---|---|
| Years | 1946–1956 | 1957–1963 | 1964–1981 | 1982–1989 | 1990 – |

the different generations of computers since the end of the Second World War.

Countries like Japan and the United States, in particular, are continuing to develop circuits and systems based on Very Large Scale Integration (VLSI), with the aim of competing favourably in world markets, but at the same time producing reliable products.

## ELECTRONICS, SOCIETY AND INDUSTRY

The electronics industry has been heavily influenced by research, development and demands in developed countries. Up to the early 1970s, manufacturing of electronics was largely concentrated in Europe and North America. However, because of competition and profit-making incentives, the electronics industry has also been spreading into the developing world over the last twenty-five years.

Exports of electronic products from Taiwan, Hong Kong, Singapore, Republic of Korea, Malaysia and Mexico constitute multibillion-dollar-a-year industries. In each of these countries production has emerged and grown in response to external demand, and the industry is almost entirely export-oriented.

Electronics manufacturers in Japan and the United States have played the role of primary financiers by establishing their own production subsidiaries, or by subcontracting with independent firms whose production costs are low. Finished products carry the name and labels of these backers. During the past twenty years or so, multinationals have transplanted their production activities exclusively to developing countries in Asia, Central America and South America. The main and basic motivation has been the quest for lower production costs and abundant, trainable labour. All those products that require labour-intensive inputs have been relocated to developing countries. Also, countries with some developed transport and communication, appropriate educational facilities, and a large, disciplined and highly motivated labour force have attracted multi-national electronic industries. With respect to China, there was a lag in the electronics industry due to the Cultural Revolution of 1966. By 1978, China was about 15 years behind the United States and Japan in the area of integrated circuits, telecommunications, automobile engineering, and computers and data communications.

Establishing an electronics industry in Africa is quite possible and would be cost-competitive with Asian electronics manufacturers if tariffs on imported components and materials were exempted and European duties on imports of the completed products were eliminated under preferential arrangements. It is true that a number of African countries have privatized their economies, but there is still political uncertainty, high costs for training, undeveloped transport and poor communications infrastructure, all of which discourage investment in the electronics industry.

As far as society is concerned, we should not overlook the major contributions of electronics to human welfare. Among those of major import during the past forty years have been the use of satellites to extend education and health services, ground sensors for peace keeping, microprocessors in the development of generations of computers, improvement in the design of more efficient energy storage

devices and transmission networks. The development of electronics during the last century has been marked by a number of milestones: namely, the discovery of the triode (audion) in 1907 by De Forest, and its utilization in amplification; the discovery of the negative feedback amplifier by Harold Black in 1927, which played a major part in long distance telephone and television networks (Plate 87), military electronics, and industrial applications, and also revolutionized the entire area of control; the discovery of the junction transistor in 1948 by W. Shockley, John Bardeen and Walter Brattain; the development of the concept of integrated circuits by Kilby in 1958; and subsequent manufacturing of ICs, Large Scale Integration (LSI) and Very Large Scale Integration (VLSI) using the planar process.

## CONCLUSION

The last century witnessed a revolutionary transformation of human activities by the electronics industry. This industry has brought a new paradigm to people's thinking and work habits. Instrumentation has opened up new frontiers in research – in medicine, biology, telecommunications, astronomy – all of which have provided new insights in the nature and workings of the Universe.

## APPLIED ASTRONOMY AND INTERPLANETARY SPACE EXPLORATION

---

*Eriabu Lugujjo*

## THE HISTORY OF ASTRONOMY

It is difficult to explain the development of astronomy during the last century without referring to contributions made by the early pioneers. Nicholas Copernicus (1473–1543), for example, spent time observing and making calculations and reached the conclusion that the Earth was just a planet orbiting the Sun. This theory matched all observations and was wonderfully simple – but the Church did not like it. Tycho Brahe (1546–1601), a Danish astronomer, amassed huge amounts of data on planetary motions. Unfortunately for him, he was a believer in the geocentric theory and never looked at his work in another light. Johannes Kepler (1571–1630) started to analyse Tycho's data and realized that it only fit if applied within the Copernican (heliocentric) theory. In 1609, he formulated the equations for orbiting planets and satellites. In particular, he determined that the planets move in ellipses rather than circles. Galileo Galilei (1564–1642) made many discoveries but also ran into conflict with the Catholic Church. He used one of the first-ever telescopes to observe the Moon, Venus, the Sun and Jupiter. His downfall came when he published works that agreed with Copernicus' heliocentric theory. He was tried by a religious tribunal and ordered not to publish any books about the Copernican theory. Galileo never recanted, and today we also remember him for his quietly defiant words at the trial: 'It still moves'.

Sir Isaac Newton (1642–1727) worked in many fields, but his chief contribution to astronomy was the discovery of the laws of gravitation. These laws held true for four hundred years until Einstein's theory of relativity. He established the three fundamental laws of force, motion, and gravitation and invented a new branch of mathematics in the process, called calculus. Newton did all this to show how the force of gravity is the reason that planetary orbits follow Kepler's equations. By the late 1800s, scientists were becoming aware of the need to revise the old Newtonian-based physics and develop a new theory. The laws of Newtonian principles were beginning to show their limits; for example, the precession of Mercury's orbit could not be completely accounted for. Albert Einstein (1879–1955) revolutionized all aspects of science and modern thought through his theories of general and special relativity, and the idea of equivalence. However, he was only taken seriously after rigorous testing of his theories. One example is the famous advance of Mercury's perihelion. Because Newton's law did not correctly predict this, Einstein's theory gained approval for a new revolution in science. With this revolution and the space age of the twentieth century, the world could once again boast of having achieved scientific and mathematical progress equal to that of the early Greeks.

## THE EXPLORATION OF SPACE

'The Earth is the cradle of mankind – one cannot remain in the cradle forever'. So said Konstantin Tsiolkovsky, a Russian schoolteacher.

The pioneers of spacecraft design, who worked out almost all theory of space flight over a period of nearly three centuries – from 1600 to 1900 – were Johannes Kepler, Sir Isaac Newton and Konstantin Tsiolkovsky (1857–1935).

Tsiolkovsky was a modest Russian schoolteacher who in 1903, without ever launching a single rocket himself, was the first to figure out all the basic equations for rocketry. He anticipated and solved many of the problems associated with rocket-powered flight and drew up several rocket designs. He determined that liquid fuel rockets would be needed to get to space, and that the rockets would need to be built in stages. He concluded that oxygen and hydrogen would be the best fuels to use.

By contrast with Tsiolkovsky, Robert Goddard (1882–1945) was the man who actually designed, built and flew the rockets. He was a university professor who also developed the theory of rocketry and, although he didn't know about Tsiolkovsky's work, he reached the same conclusions. Goddard conducted practical experiments in rocketry early in the twentieth century. He was interested in achieving higher altitudes than were possible for lighter-than-air balloons, and in 1919 he published a pamphlet entitled *A Method of Reaching Extreme Altitudes*. It was a mathematical analysis of what is today called a meteorological sounding rocket.

In 1926, Goddard launched the world's first liquid-fuelled rocket, and he is widely considered the foremost pioneer of rocket technology. Working independently, he developed the same components and designs that took the Germans hundreds of scientists and engineers and millions of dollars to develop during the Second World War. Goddard's earliest experiments involved solid-propellant rockets. In 1915, he tried to measure the exhaust velocities of the burning gases using various types of solid fuels. While working on solid-propellant rockets, Goddard became convinced that a rocket could best be propelled by liquid fuel. He achieved the first successful flight with a liquid-propellant rocket on 16 March 1926. Fuelled by liquid oxygen and gasoline, the rocket flew for only two and a half seconds, climbed 12.5 metres, and landed 56 metres away.

Goddard's rockets became bigger and flew higher. He developed a gyroscope system for flight control and a payload compartment for scientific instruments. Parachute recovery systems were employed to return rockets and instruments safely.

Hermann Oberth (1894–1989),[1] another great space pioneer from Germany, published a book in 1923 about rocket travel into outer space. Because of the book, many small rocket societies sprang up around the world. In Germany, the formation of one such society, the Verein fur Raumschiffahrt (Society for Space Travel) led to the development of the V-2 rocket, which was used against London during the Second World War. In 1937, German engineers and scientists, including Oberth, assembled in Peenemuende on the shores of the Baltic Sea to work in a rocket research facility built by Hitler.

The V-2 rocket (in Germany called the A-4) was small by comparison to today's rockets. It achieved its great thrust by burning a mixture of liquid oxygen and alcohol at a rate of about one ton every seven seconds. Nevertheless, by the end of the war, German rocket scientists and engineers had already laid plans for advanced missiles capable of spanning the Atlantic Ocean and landing in the United States. With the fall of Germany, the Allies captured many unused V-2 rockets and components, and many German rocket scientists emigrated to the United States and the Soviet Union. Both countries realized the potential of rocketry as a military weapon and began a variety of experimental programmes. At first, the United States launched a programme with high-altitude atmospheric sounding rockets, one of Goddard's early ideas. Later, a variety of medium- and long-range intercontinental ballistic missiles were developed. These became the starting point of the US Space programme. Missiles such as the Redstone, Atlas, and Titan would eventually launch astronauts into space.

## Trends in Space Exploration

Sergei Korolev, earlier known anonymously in the USSR as 'Chief Designer', was inspired by the work and visions of Tsiolkovsky. He informed the Soviet Union Council of Ministers in 1954 that an artificial Earth Satellite could be launched in a few years' time, and he was as good as his word. On 4 October 1957, *Sputnik 1* – the first man-made object to orbit the Earth – was launched by the USSR and remained in orbit until 4 January 1958.

The news that the Soviets had launched *Sputnik 1* hit the Western countries, and in particular the United States, like

a bombshell. As the world watched American rockets explode with embarrassing regularity, the Soviets launched *Sputnik 2* on 3 November 1957. This satellite carried a dog that survived in space for seven days (i.e. until its oxygen was exhausted). The United States succeeded in sending a satellite into orbit on 31 January 1958, thus marking the start of a 'Space Race' essentially to send a person into orbit. These scientific advancements were propelled by a desire for international prestige and national security, and they were a way of demonstrating to the entire world the advantage of a particular political ideology.

The United States was so determined to explore space that, on 1 October 1958, the National Aeronautics and Space Administration (NASA) was created to take over the duties of the National Advisory Committee for Aeronautics (NACA), which was founded in 1915. Within a few days of its creation, NASA initiated Project Mercury, whose stated objective was placing a man in space and returning him safely to Earth. Meanwhile the USSR was making great strides in launching satellites to orbit the Sun, and it succeeded in January 1959 with *Luna 1*. In 1961, it launched *Vostok 1* carrying cosmonaut Yuri A. Gagarin, the first person in space. He completed a single orbit of the Earth (Plate 88).

Meanwhile, NASA was making long-term preparations not only to orbit the Earth but also to explore space, starting with the Moon and on to Mars. In January 1962, *Friendship 7* lifted off with John H. Glenn Jr., who orbited the Earth three times and became the first American in orbit. In the same year, the US *Mariner 2*, the first successful planetary spacecraft, flew past Venus and entered a solar orbit. More was to come from the Soviets, however. In 1963, cosmonaut Valentina Tereshkova, the first woman in space, orbited the Earth forty-eight times in *Vostok 6*.

Both the Soviets and Americans were determined to explore space using manned flights and by landing a person on the moon. Many flights and experiments were made, and the period 1965–69 could be described as experimental, eventful and extremely trying years for both countries. These efforts were rewarded and culminated in the first manned soft lunar landing, by Neil Armstrong and Edwin Aldrin on 20 July 1969, aboard *Apollo 11*. The success of the *Apollo* programme triggered a wave of launches to the Moon, Venus and Mars. The USSR's *Lunar 17* landed on the Moon with the first automatic robot, *Lunokhod 1*, on 17 November 1970. In the same year, the Soviet's *Verena 7* was the first probe to achieve a soft landing on Venus. Ever since then there have been many launches and successes yielding invaluable knowledge about space and the planets. An attempt to sequence these events has been made and is presented in an annex to this section.

## RADIO ASTRONOMY

Radio astronomy deals with the study of distant objects in the universe by collecting and analysing the radio waves they emit. It has been a major factor in revolutionizing our understanding of the universe and how it works. Radio observations have provided a whole new outlook on objects we thought we already knew, such as galaxies, while revealing the existence of other unexpected objects such as pulsars and quasars. Radio telescopes today are among the most powerful tools available for astronomers studying nearly every type of object known in the universe.

## Early radio astronomy

Following Marconi's successful transatlantic communications in 1901, commercial use of radio mushroomed. It was thought that the only useful frequencies for long-range communication were the very low frequencies, or the very long wavelengths. Thus, when the first government regulations were imposed on radio in 1912, the amateur operators, whose interest in the medium was personal and experimental, rather than commercial, got the short end of the stick. They were given the use of wavelengths of 200 metres and shorter.

As we know today, short-wave communication is subject to much noise and static. Companies using short-wave therefore sought to identify and find ways of mitigating this noise. At AT&T Bell Labs in New Jersey, a young radio engineer named Karl Janksy was assigned the task of identifying the sources of short-wave noise. He built a highly directional antenna to work at about 22 MHz, and began to make systematic observations. Most of the noise he found was due to thunderstorms and other terrestrial causes. However, one source of static that seemed to appear four minutes earlier every day was also found. What Jansky had discovered was radio noise emitted from the centre of our Milky Way Galaxy. Janksy made his discovery in 1932, and it was made public in 1933.

In 1937, Grote Reber built a 32-foot-diameter parabolic dish antenna in his backyard, which enabled him to detect cosmic radio emissions by 1939. Two years later, he made his first survey of the sky at radio wavelengths.

## Astronomy and the environment

Like every other human endeavour, exploration of the universe takes place in the context of our terrestrial environment. As human activity changes that environment, issues are raised for both astronomers and those who enjoy the fruits of their research.[2]

Among these are problems caused by 'light pollution', the issue of reconciling the need for new observatory sites with the safeguarding of endangered species, the difficulty of protecting the frequencies needed for radio astronomy from the encroachment of cellular phones and other forms of radio communication on Earth, and the problem of how we protect other planets from Earth's micro-organisms and the Earth from possible extraterrestrial microbes.

### Light pollution

Fewer and fewer places on Earth remain truly dark at night, as electric lights spread across the globe. For astronomers trying to collect the faint light of distant objects, this 'light pollution' is a serious problem. Some lights are worse than others in terms of the number of wavelengths they block from celestial objects. Steps have to be taken to balance the lighting needs of cities with the requirements of scientists doing research.

### Observatory sites and the environment

While many new observatories must now file an environmental impact statement, the most publicized clash between astronomers and environmentalists was over a site in Arizona (USA) called Mount Graham, where there was some concern about an endangered species of squirrel.

### Radio interference

Radio astronomers search for 'faint' radio static from cosmic objects. Increasingly, the signals they search for are lost in the noise of terrestrial radio communications, particularly the requirements of cellular phones and other modern communications using satellites.

### Preventing the contamination of Earth or other worlds

As robotic probes travel to the other bodies in our solar system, and even begin to return samples to Earth, the issue of planetary contamination must be confronted. How do we keep our microbes from hitching a ride to other worlds, and how do we prevent any possible celestial microbes from getting to Earth and (possibly) harming life on our planet?

## INFRARED ASTRONOMY

Infrared astronomy deals with the detection and study of the infrared radiation (heat energy) emitted from objects in the universe.[3] Every object that has a non-zero temperature radiates in the infrared. In the field of astronomy, the infrared region lies within the range of sensitivity of infrared detectors, which is between about 1 and 300 microns. The human eye detects only 1 per cent of light at 0.69 microns, and 0.01 per cent at 0.75 microns, and so effectively cannot see wavelengths longer than about 0.75 microns unless the light source is extremely bright. So infrared astronomy provides us with a window through which we can view what would otherwise be invisible.

The universe sends us a tremendous amount of information in the form of electromagnetic radiation. Only a small amount of this infrared information reaches the Earth's surface, yet by studying this small range of infrared wavelengths, astronomers are able to uncover a wealth of new information.

Only since the early 1980s have infrared telescopes been sent into orbit around the Earth and above the atmosphere, which hides most of the universe's electromagnetic radiation from us. The first of these satellites – IRAS (Infrared Astronomical Satellite) – detected about 350,000 infrared sources, increasing the number of catalogued astronomical sources by about 70 per cent.

### Exploring the universe

In the infrared, astronomers can gather information about the universe. Astronomers have discovered that all distant galaxies are moving away from us and that the farther away they are, the faster they are moving. When an object is moving away from us, the light that it emits is 'redshifted'. This means that the wavelengths get longer and are thus shifted towards the red part of the spectrum. As a result of this Doppler Effect, at large redshifts, all of the ultraviolet and much of the visible light from distant sources is shifted into the infrared part of the spectrum by the time it reaches our telescopes. Thus the only way to study this light is in the infrared itself.

## Infrared radiation

This is electromagnetic radiation with a wavelength longer than that of visible light, extending from about 1 micrometer to 1 millimetre. The primary source of infrared radiation is heat or thermal radiation. Any object which has an above absolute zero (-459.67 °F or -273.15 °C or 0 Kelvin), radiates in the infrared.

In infrared observations, a telescope collects radiation, just as in the optical region. The incoming radiation consists of radiation from the object, from the background and from the telescope itself. Both source and background must be continually measured, the difference giving the radiation from the object.

With infrared analysis, it is possible to determine the average surface temperatures of the planets, which range from about -400 °C for Mars to below -1,750 °C for Saturn.

## The emission mechanism

Objects in space are surrounded by dense clouds of very cold material, circumstellar shells whose grains and dust particles absorb photons of higher energy and reradiate the energy as large numbers of low energy infrared photons at infrared wavelengths corresponding to their temperatures. Thermal radiation is of particular interest for extraterrestrial objects possessing extensive atmospheres, since it would be expected to originate in a deeper layer than optical light. In space, there are many regions that are hidden from optical telescopes because they are embedded in dense regions of gas and dust. However, infrared radiation, having wavelengths that are much longer than visible light, can pass through dusty regions of space without being scattered. This means that we can study objects hidden by gas and dust in the infrared, which we cannot see in visible light, such as the centre of our galaxy and regions of newly forming stars. Terrestrial infrared observatories need to be built on high mountaintops, below which most of the atmospheric water vapour remains. This is because the vapour absorbs infrared radiation significantly. For observations in the far infrared, mountains are not high enough; observations are thus carried out on aeroplanes, balloons and satellites.

## Detecting cool objects

Many objects in the universe that are much too cool and faint to be detected in visible light can be detected in the infrared. These include cool stars, infrared galaxies, nebulae, interstellar molecules, planets, and clouds of particles around stars. For example, the visible light from a planet is hidden by the brightness of the star that it orbits. In the infrared, where planets have their peak brightness, the brightness of the star is reduced, making it possible to detect a planet in the infrared.

## Infrared spectroscopy

Determining which atoms and molecules are present in space, what their distribution and abundance are, and in what environments they exist is critical to our understanding of the universe, the formation of stars, planets and galaxies, and the possibility of life beyond Earth. The infrared part of the spectrum is where the emission and absorption lines of virtually all molecules as well as numerous atoms and ions lie. Spectrometers onboard infrared missions like the Kuiper Airborne Observatory (KAO) and the Infrared Space Observatory (ISO), as well as near-infrared spectra from ground-based observatories, have led to the discovery of hundreds of atoms and molecules in many different regions of space.

## CONCLUSION

Since its inception, the science of astronomy had been limited to the observation of objects in the visible light spectrum. The detection of radio emissions added a new dimension to our perception. From Reber's modest backyard antenna built in 1937, to the James Clerk Maxwell Telescope with its state-of-the-art multi-feed receiver system, single-dish radio telescopes have made great contributions to radio astronomy. The single-dish telescope has not been rendered obsolete by interferometers; rather, they work together as a complementary couple, with single-dishes giving an overview of the large-scale structure of the cosmos, and interferometers revealing the fine details. The astronomical research programmes carried out by single-dish radio telescopes have expanded our skyview, thus enabling a better understanding of the universe. Objects that can be seen in visible light can also be studied in the infrared. In addition to discovering new objects and viewing previously unseen areas of the universe, infrared astronomy can add to what we already know about visible objects. To get a complete picture of any object in the universe we need to study all the radiation that it emits.

## ANNEX: A CHRONOLOGY OF SPACE EXPLORATION[4]

**1856** – Astronomers use thermocouples and thermopiles to detect infrared radiation from the Moon.

Early **1900s**, infrared radiation is detected from the planets Jupiter and Saturn and from some bright stars.

**4 October 1957** – *Sputnik 1*, the first man-made object to orbit the Earth, is launched by the USSR, and remains in orbit until 4 January 1958.

**3 November 1957** – *Sputnik 2*, is launched by the USSR, and remains in orbit until 13 April 1958.

**31 January 1958** – *Explorer 1*, the first US satellite in orbit, lifts off at Cape Canaveral using a modified ABMA-JPL Jupiter-C rocket.

**5 March 1958** – *Explorer 2* is launched by a Jupiter-C rocket, and fails to reach orbit.

**17 March 1958** – *Vanguard 1* satellite is launched into orbit.

**15 May 1958** – *Sputnik 3* is launched by the USSR.

**1 October 1958** – NASA is founded, taking over the existing National Advisory Committee for Aeronautics.

**11 October 1958** – *Pioneer 1*, US-IGY space probe, is launched to a height of 70,700 miles.

**2 January 1959** – The USSR launches *Luna 1*, the first man-made satellite to orbit the Sun.

**3 March 1959** – *Pioneer 4*, the fourth US-IGY space probe, is launched by a Juno II rocket, and achieves an Earth-Moon trajectory, passing within 37,000 miles of the Moon.

**12 September 1959** – *Luna 2*, bearing the Soviet coat of arms, is launched, hitting the Moon on September 13.

**4 October 1959** – *Luna 3* translunar satellite is launched and orbits the Moon.

**1 April 1960** – *Tiros 1*, the first successful weather satellite, is launched by the US.

**18 August 1960** – *Discoverer XIV* launches the first US camera-equipped Corona spy satellite.

**12 April 1961** – *Vostok 1* is launched by the USSR, carrying cosmonaut Yuri A. Gagarin, the first man in space, who orbits the Earth once.

**5 May 1961** – Mercury *Freedom 7* carries Alan B. Shepard, Jr., the first American in space, into a sub-orbital flight.

**6 August 1961** – The USSR launches *Vostok 2*.

**1961** – Development of the germanium bolometer, which works best at an extremely low temperature.

**20 February 1962** – Mercury *Friendship 7* lifts off with John H. Glenn, Jr., who orbits the Earth three times.

**24 May 1962** – Mercury *Aurora 7* is launched and completes three orbits.

**10 July 1962** – US satellite *Telstar 1* beams the first live transatlantic telecast.

**14 December 1962** – US *Mariner 2*, the first successful planetary spacecraft, flies past Venus and enters a solar orbit.

**16 June 1963** – *Vostok 6* carries Soviet Cosmonaut Valentina Tereshkova, the first woman in space, and orbits the Earth 48 times.

**31 July 1964** – US *Ranger 7* relays the first close-range photographs of the Moon.

**18 March 1965** – Alexei A. Leonov makes the first space walk from Soviet *Voskhod 2*.

**23 March 1965** – First manned flight of the Gemini programme, *Gemini 3*.

**24 March 1965** – *Ranger 9* transmits high-quality images of the Moon.

**3 June 1965** – Edward White II makes the first US space walk from *Gemini 4*.

**14 July 1965** – US *Mariner 4* returns the first close-range images of Mars.

**16 November 1965** – Soviet *Venera 3* is launched and impacts Venus on 1 March 1966.

**4 December 4 1965** – *Gemini 7* is launched carrying Frank Borman and James A. Lovell, Jr., making 206 orbits around Earth and proving a trip to the Moon possible.

**15 December 1965** – American astronauts Walter Schirra, Jr. and Thomas Stafford in *Gemini 6* make the first space rendezvous with *Gemini 7*.

**3 February 1966** – Soviet *Luna 9* is the first spacecraft to soft-land on the Moon.

**1 March 1966** – Soviet *Venera 3* impacts on Venus, the first spacecraft to reach another planet. It fails to return data.

**March 1966** – Soviet *Luna 10* is the first spacecraft to orbit the Moon.

**2 June 1966** – *Surveyor 1* is the first US spacecraft to soft-land on the Moon.

**14 August 1966** – US *Lunar Orbiter 1* enters Moon orbit, and takes the first picture of the Earth from the distance of the Moon.

**23 April 1967** – Soviet *Soyuz 1* is launched, carrying Vladimir M. Komarov. On 24 April it crashes, killing Komarov, the first spaceflight fatality.

**18 October 1967** – *Venera 4* sends a descent capsule into the Venusian atmosphere, returning data about its composition.

**15 September 1968** – Soviet *Zond 5* is launched, the first spacecraft to orbit the Moon and return.

**11 October 1968** – *Apollo 7* is the first manned Apollo mission, with Walter M. Schirra, Jr., Donn F. Eisele, and Walter Cunningham. It orbits the Earth once.

**21 December 1968** – *Apollo 8* is launched using the *Saturn V* rocket, thus becoming the first manned spacecraft to orbit the Moon and making 10 orbits on its 6-day mission.

**January 1969** – *Soyuz 4 and 5* perform the first Soviet spaceship docking, transferring cosmonauts between vehicles.

**20 July 1969** – Using *Apollo 11*, Neil Armstrong and Edwin (Buzz) Aldrin, Jr., make the first manned soft landing on the Moon, and the first moonwalk.

**31 July 1969** – *Mariner 6* returns high-resolution images of the Martian surface, concentrating on the equatorial region.

**5 August 1969** – *Mariner 7* returns high-resolution images of the Martian surface, concentrating on the southern hemisphere.

**11 April 1970** – *Apollo 13* is launched, suffering an explosion in its oxygen tanks. Its Moon landing is aborted, and the crew returns safely.

**12 September 1970** – Soviet *Luna 16* is launched, conducting the first successful return of lunar soil samples by an automatic spacecraft.

**17 November 1970** - *Luna 17* lands on the Moon, with the first automatic robot, *Lunokhod 1*. Driven from Earth by a five-person team, it travels over the surface for 11 days.

**15 December 1970** – Soviet *Venera 7* is the first probe to soft-land on Venus.

**1970s** – Astronomers around the world begin to consider the possibility of placing an infrared telescope on a satellite in orbit around the Earth.

**31 January 1971** – The US launches *Apollo 14* (Moon mission).

**19 April 1971** – *Salyut 1* space station is launched by the USSR. It remains in orbit until 28 May 1973.

**30 May 1971** – The United States launches *Mariner 9*, which becomes the first spacecraft to survey Mars from orbit.

**13 November 1971** – US *Mariner 9* (launched 30 May 1971) is the first spacecraft to orbit another planet, Mars.

**2 March 1972** – *Pioneer 10* is launched on an Atlas/Centaur/TE364-4 towards Jupiter by the US, designed to familiarize alien life with humans.

**15 July 1972** – *Pioneer 10* becomes the first man-made object to travel through the asteroid belt.

**5 April 1973** – *Pioneer 11* is launched on an Atlas/Centaur/TE364-4, flying past Jupiter in 1974, and Saturn in 1979, where it discovers new rings.

**14 May 1973** – *Skylab* Workshop is launched by the US and maintained by three crews.

**25 May 1973** – First crew to *Skylab 2* is launched, repairing damage incurred to *Skylab* during its launch.

**3 November 1973** – American *Mariner 10* is launched, on the first dual-planet mission.

**17 May 1974** – NASA launches the first Synchronous Meteorological Satellite, SMS-1.

**24 June 1974** – Soviet *Salyut 3*, their first military space station, is launched.

**26 December 1974** – Soviet *Salyut 4*, a civilian space station, is launched.

**22 June 1976** – Soviet military space station *Salyut 5* is launched.

**August–September 1977** – *Voyagers 1* and 2 leave Earth to reach Jupiter in 1979 and Saturn in 1980.

**3 September 1976** – *Viking 2* lands on Mars on the Plain of Utopia.

**29 September 1977** – Soviet *Salyut 6* space station is launched.

**1977** – An international collaboration is formed by the Netherlands, United States and Great Britain to develop IRAS, the Infrared Astronomical Satellite.

IRAS is launched on 25 January 1983 with an array of 62 detectors.

It increases the number of catalogued astronomical sources by about 70 per cent, detecting about 350,000 infrared sources. IRAS discoveries include a disk of dust grains around the star Vega, six new comets, and very strong infrared emission from interacting galaxies.

Many of the new advances in infrared radiation arose from US Department of Defense research into infrared array technology in the 1980s. Development of infrared array detectors in this period causes another giant leap in the sensitivity of infrared observations. These arrays allow astronomers to produce images containing tens of thousands of pixels at the same time.

**November 1978** – The Einstein Observatory begins its thirty-day mission.

**December 1978** – Two *Pioneer* spacecraft reach Venus, which is 38.2 million km, at its closest, from Earth.

**1 September 1979** – *Pioneer 11* reaches Saturn, flying to within 13,000 miles and taking the first close-up photographs.

**12 April 1981** – The first manned mission of the Space Transportation System (STS-1), *Columbia*, is launched.

**19 June 1981** – The European Space Agency launches its third Ariane rocket.

**1 March 1982** – *Venera 13* lands on Venus, and provides the first Venusian soil analysis.

**19 April 1982** – Soviet *Salyut 7* space station is launched.

**13 May 1982** – Soviet cosmonauts are launched in *Soyuz-T 5* to rendezvous with *Salyut 7*. They return to Earth in *Soyuz-T 7*.

**August 1982** – *Voyager 2* completes its flyby of Saturn.

**11 November 1982** – The space shuttle *Columbia's* fifth mission deploys two satellites.

**4 April 1983** – The space shuttle *Challenger* lifts off for its first mission (STS-6).

**19 June 1983** – Sally Ride is first US woman in space, on *Challenger* mission STS-7.

**10 October 1983** – Soviet *Venera 15* returns images of Venus' polar area.

**28 November 1983** – The space shuttle *Columbia* carries the European Space Agency (ESA) Spacelab-1 into orbit (STS-9). Its crew includes Ulf Merbold, a German and first ESA member in space.

**January–November 1983** – The Infrared Astronomical Satellite finds new comets, asteroids, galaxies, and a dust ring around the star Vega that may be new planets.

**3 February 1984** – Bruce McCandless takes the first untethered space walk from the space shuttle *Challenger* (STS-41B) (Plate 89).

**30 August 1984** – The third space shuttle, *Discovery*, lifts off on its maiden voyage (STS-41D).

**5 October 1984** – Launch of space shuttle *Challenger* mission STS-41G carrying the first crew with two women aboard – Sally Ride and Katherine Sullivan.

**December 1984** – Soviet/International *Vega 1* and 2 are launched, dropping probes into Venus' atmosphere before continuing to Halley's comet.

**8 January 1985** – Japan's Institute of Space and Aeronautical Science launches the Sakigake probe.

**29 April 1985** – The *Challenger* carries the ESA Spacelab-3 into orbit (STS-51B).

**2 July 1985** – The European Space Agency launches the Giotto spacecraft from an Ariane rocket.

**July–August 1985** – An infrared telescope is flown onboard the Space Shuttle's *Spacelab 2* to complement observations made by the IRAS mission. This mission produces a high-

quality map of about 60 per cent of the plane of our galaxy.

**3 October 1985** – The fourth shuttle *Atlantis* takes off on its first mission (STS-51J).

**October 1985** – *Spacelab D1*, the first joint German/ESA mission, is flown.

**January 1986** – *Voyager 2* flies past Uranus.

**20 February 1986** – The core unit of Soviet space station *Mir* is launched.

**March 1986** – Astronomers discover an invisible gravity source that splits a quasar's light.

**April 1986** – Astronomers find that our galaxy is smaller than they thought and the Sun is 23,000 light-years from its centre.

**December 1987** – Cosmonaut Yuri V. Romanenko returns from space station *Mir*, having arrived there from *Soyuz-TM 2*.

**4 May 1989** – Space Shuttle *Atlantis* is launched (STS-30), deploying the spacecraft *Magellan*.

**18 October 1989** – US launches the *Galileo* spacecraft from Shuttle *Atlantis* flight STS-34, which takes infrared images of Venus and asteroid Ida, before continuing to Jupiter.

**November 1989** – NASA launches the COBE satellite to study both infrared and microwave characteristics of the cosmic background radiation. COBE maps the brightness of the entire sky at several infrared wavelengths and discovers that the cosmic background radiation is not entirely smooth.

**5 April 1990** – US *Pegasus* rocket is deployed from a B-52 bomber, and launches the *Pegsat* satellite in the first demonstration of the *Pegasus* launch vehicle.

**24 April 1990** – Space Shuttle *Discovery* launches on STS-31, deploying the *Edwin P. Hubble Space Telescope* (HST) astronomical observatory.

**August 1990** – US spacecraft *Magellan* arrives at Venus.

**6 October 1990** – Space Shuttle *Discovery* launches the *Ulysses* spacecraft with two upper stages, on mission STS-41.

**7 February 1991** – *Salyut 7* falls from orbit and burns up over Argentina.

**5 April 1991** – Space Shuttle *Atlantis* carries the *Compton Gamma Ray Observatory* into orbit.

**5 June 1991** – Shuttle *Columbia* carries the *Spacelab* SLS-1 into orbit, to conduct investigations into the effects of weightlessness on humans.

**2 May 1992** – Space Shuttle *Endeavour* lifts off on its first mission (STS-49), repairing the Intelsat VI satellite.

**25 September 1992** – *Mars Observer* lifts off, the first American probe to Mars since *Viking 2* in 1976.

**2 December 1993** – Space Shuttle *Endeavour* launches on STS-61, making the first on-orbit service of the *Hubble Space Telescope* (HST).

**25 January 1994** – US launches *Clementine*, a new DOD satellite that performs a lunar mapping mission using advanced ballistic missile defence technologies.

**February 1994** – A Russian cosmonaut, Sergei Krikalev, flies on board the US space shuttle *Discovery* for the first time (STS-60).

**12 October 1994** – Spacecraft *Magellan* enters the atmosphere of Venus, burning up following the completion of its mapping mission.

**6 February 1995** – Space shuttle *Discovery* manoeuvres to within 37 feet of Russian space station *Mir*, in preparation for a shuttle-*Mir* docking (STS-63) (Plate 90).

**March 1995** – Japan launches the Infrared Telescope in Space (IRTS).

**26 June 1995** – Space Shuttle *Atlantis* rendezvous with Russian space station *Mir* during a ten-day mission on STS-71.

**September 1995** – *Pioneer 11* ceases making scientific observations, its power source nearly depleted.

**12 November 1995** – Space Shuttle *Atlantis* lifts off on mission STS-74, making the second docking with Russian space station *Mir*.

**November 1995** – The European Space Agency launched the Infrared Space Observatory (ISO), which observes at wavelengths between 2.5 and 240 microns.

**7 December 1995** – The Galileo spacecraft arrives at Jupiter.

**8 February, 1996** – Thomas Reiter becomes the first European Space Agency astronaut to make two space walks (both from the Russian *Mir* space station).

**17 February 1996** – NASA launches the first in the *Discovery* series of spacecraft, the Near-Earth Asteroid Rendezvous (NEAR) spacecraft, aboard a Delta II-7925-8 rocket.

**April 1996** – The Midcourse Space Experiment (MSX) is launched and lasts until its liquid helium coolant runs out in Feb. 1997, gathering a vast amount of data at 4.2–26 microns.

**19 November 1996** – Space Shuttle *Columbia* lifts off on its twenty-first space flight, setting a new shuttle in-space endurance record of almost 18 days.

**12 January 1997** – Space Shuttle *Atlantis* lifts off for the fifth docking with the *Mir* space station.

**31 March 1997** – After 25 years of operation, routine telemetry and ground control with *Pioneer 10* are terminated. The probe at that moment is 6.7 billion miles from Earth, travelling at 28,000 miles per hour. In two million years, it will reach the red giant Aldeberan in the constellation of Taurus.

**1 July 1997** – Space Shuttle *Columbia* lifts off again to complete the flight aborted in April. The shuttle is outfitted with *Spacelab*, set up as a microgravity science laboratory.

**4 July 1997** – *Mars Pathfinder* becomes the first probe to successfully land on Mars since *Viking 2* in 1976.

**7 August 1997** – Space Shuttle *Discovery* lifts off for a 12-day mission to deploy and retrieve the *Crista-Spas 2* satellite, which studied the Earth's middle atmosphere.

**27 September 1997** – Space Shuttle *Atlantis* performs its seventh docking with *Mir* to support the repair and upgrade process.

**19 November 1997** – Space Shuttle *Columbia* lifts off with three American astronauts, one Japanese, and the first Ukrainian astronaut, Leonid Kadenyuk.

**7 January 1998** – *Lunar Prospector* is the first NASA mission to the Moon in 25 years, and the first dedicated to lunar research since *Apollo 17* in 1972.

**22 January 1998** – Space Shuttle *Endeavour* lifts off to rendezvous with *Mir*, the eighth US docking with the Russian space station and the first by a shuttle other than *Atlantis*.

**17 April 1998** – Space Shuttle *Columbia* lifts off on a 16-day mission, its 25th.

**2 June 1998** – Space Shuttle *Discovery* lifts off on a 10-day mission, its 24th and the last shuttle docking with *Mir*.

**3 July 1998** – Japan launches the *Nozomi* probe to Mars.

**3 October 1998** – Launched by the US National Reconnaissance Office, the *Space Technology Experiment (STEX)* satellite tests 29 new spacecraft designs.

**24 October 1998** – NASA launches *Deep Space 1*, a technology test spacecraft that evaluates a dozen advanced spacecraft engineering designs.

**20 November 1998** – The first component of the International Space Station, *Zarya*, is launched on a Russian rocket.

**4 December 1998** – Space Shuttle *Endeavour* lifts off on its thirteenth space flight, with the International Space Station's second module, *Unity*.

**11 December, 1998** – NASA launches *Mars Climate Orbiter*, with the objective of studying Martian weather. The probe is lost as it approaches Mars on 23 September 1999, due to an error in propulsion software, using English instead of metric units.

**3 January 1999** – *Mars Polar Lander* lifts off on its ill-fated mission to Mars. This NASA probe is to land within about 600 miles of the Martian South Pole. Contact with the probe is lost on 3 December 1999, and it is never heard from again.

**7 February 1999** – The NASA satellite *Stardust* lifts off for a rendezvous with the Comet Wild-2 in January of 2004.

**27 May 1999** – Space Shuttle *Discovery* lifts off for the International Space Station.

**19 November 1999** – China launches *Shenzhou*, the first unmanned test of their manned capsule.

**19 December 1999** – Space Shuttle *Discovery* lifts off for the third maintenance mission to the Hubble Space Telescope.

**3 January 2000** – The *Galileo* space probe safely completes its encounter with Jupiter's ice moon, Europa, at an altitude of 343 km.

**11 February 2000** – Space Shuttle *Endeavour* lifts off to carry out the Shuttle Radar Topography Mission, cosponsored by NASA and the National Imagery and Mapping Agency.

**14 February 2000** – *NEAR (Near Earth Asteroid Rendezvous)* probe settles into orbit around the asteroid 433 Eros, producing a series of stunning close-up images.

**19 May 2000** – Space Shuttle *Atlantis* lifts off for the *International Space Station (ISS)* for maintenance work on the crane and a faulty antenna; a Russian boom arm is installed.

**31 October 2000** – The *Expedition One* crew is launched on a *Soyuz* transport to become the first crew of the *ISS*.

**1 December 2000** – Space Shuttle *Endeavour* lifts off on a 12-day mission to the *ISS*.

**9 January 2001** – The first launch of the true millennium is Chinese, with the second test flight of the manned *Shenshou* spaceship.

**8 March 2001** – Space Shuttle *Discovery* is launched on a 14-day *ISS* construction mission.

**23 March 2001** – Fifteen years after its first launch, and after nearly 10 years of continuous occupation by astronauts, the *Mir* space station is de-orbited, breaking up in the atmosphere and crashing in the Pacific Ocean.

**7 April 2001** – The *2001 Mars Odyssey* probe is launched on a trajectory for Mars orbit to be achieved in October 2001.

**28 April 2001** – *Soyuz* spacecraft *TM-32* lifts off for the *ISS* with the first space tourist, business executive Dennis Tito, who pays the Russians $20 million for the ride.

**30 June 2001** – NASA's *Microwave Anisotropy Probe (MAP)* is launched on a trajectory for a gravity boost past the Moon to a position 1.5 million km outside Earth's orbit.

**12 July 2001** – Space Shuttle *Atlantis* lifts off for the *ISS* with the Joint Airlock, which will enable space walks to be performed directly from the space station itself.

**10 August 2001** – Space Shuttle *Discovery* lifts off for the *ISS* with the *Leonardo* laboratory module and *Simple Sat*, an experimental low-cost astronomical telescope.

# 17.6
# MATERIALS

*Eriabu Lugujjo*

Materials can be defined as substances possessing properties that make them useful in machines, structures, devices, and products. Materials are omnipresent and number in the thousands. Table 7 shows some materials that are of great interest to society.

Most products are made from many different kinds of materials to satisfy the needs of a product. Since there are so many different types of materials, one way to look at materials is to classify them as metals and non-metals.

## METALS AND NON-METALS

Metals are materials that are normally combinations of 'metallic elements'.[1] These elements, when combined, usually have electrons that are non-localized and as a consequence have generic types of properties. Metals are usually good conductors of heat and electricity. Also, they

are quite strong but malleable and tend to have a lustrous or shiny look when polished.

The category of non-metals includes plastics, semiconductors, ceramics, and composites. Plastics (or polymers) are generally organic compounds based upon carbon and hydrogen; they are very large molecular structures. Usually they are of low density and are not stable at high temperatures. Ceramics are generally compounds between metallic and non-metallic elements and are made from metal oxides, nitrides, silicates and carbides. Typically they are good insulators and resistant to high temperatures and harsh environments. Semiconductors have electrical properties intermediate between metallic conductors and ceramic insulators. In addition, the electrical properties are strongly dependent upon small amounts of impurities. Composites consist of more than one material type; fibreglass, a combination of glass and a polymer, is an example. Concrete and plywood are other familiar

*Table 7* **Commonly used metals**

| Classes | Examples | Principal Characteristics | Application |
|---|---|---|---|
| Metals and alloys | Steels, super-alloys, light alloys | Strength, toughness | Automobiles, aircraft, pressure vessels |
| Ceramics and cermets | Alumina, silicon nitride, metal carbides | Temperature and corrosion resistance, high hardness | Furnace refractories, engine components |
| Plastics and elastomers | Polymers, rubbers, polyurethanes | Strength, corrosion resistance, low density | Pipes, panels, process plant |
| Composites | Fibre-reinforced plastics, metals, or ceramics | Extremely tough, high strength/weight | Aircraft and other transport components |
| Construction materials | Building stone, cement | Durable, plentiful supply, cheap | Buildings, habitations, roads, bridges |
| Timber | Wood, wood composites | Ease of fabrication, strength | Furniture, buildings |
| Fibre | Cotton, nylon, glass | Diverse, manufacturing and handling ease | Textiles, fibre/plastic composites |
| Paper | Paper, paperboard | Diverse | Printing, decorating |

*Source:* Hondros, 1988.

composites. Many new combinations include ceramic fibres in a metal or polymer matrix. These metal and non-metal materials can also be characterized distinctly by their different physical and chemical properties.

## TRENDS IN MATERIALS SCIENCE AND ENGINEERING

Whereas in 1900 it was taken for granted that there were two kinds of sciences, the pure or basic, on the one hand, and the applied, on the other, this is no longer the case.[2] By pursuing simultaneously both cognitive and practical interests, emerging disciplines such as materials science overthrew this clear-cut distinction.

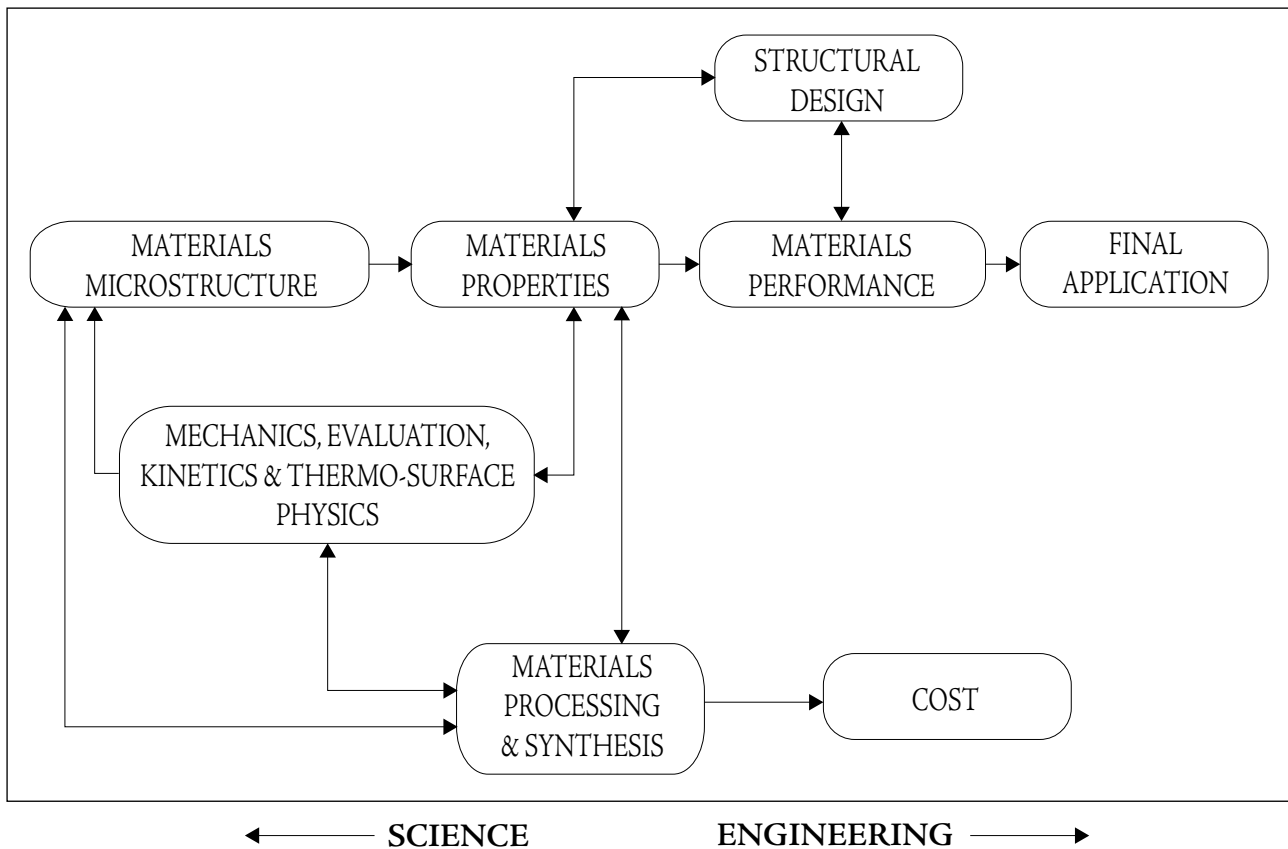
Materials science is a hybrid entity coupling fundamental research with engineering application of the end product. The generic concept of materials presupposes that such diverse substances as metals, polymers, glass, or semiconductors share certain characteristics.

The dramatic role of iron throughout the ages is not really the result of its being 'strong', as one might imagine. In reality, iron has been important because heating and cooling can modify its properties; this is just one area of materials science and engineering.

One major objective of materials science and engineering is to create materials by design, that is, structures tailored for specific purposes, whose properties are adapted to a set of specific tasks. This goal was achieved only after the development of specialized instruments providing access to the microstructure of materials. X-ray diffraction was the first of the new techniques for imaging the micro-world that fostered the development of materials science and technology. Light transmission microscopes were also used. In 1931, Max Knoll and Ernst Ruska in Germany developed the first type of electron microscope – the transmission electron microscope (TEM). The TEM is patterned exactly on the light transmission microscope except that a focused beam of electrons is used instead of light to 'see through' the specimen. Electron microscopes are scientific instruments that use a beam of highly energetic electrons to examine objects on a very fine scale. The first scanning electron microscope (SEM) was created in 1942, and the first commercial instruments became available around 1965. The SEM's late development was due to the electronic difficulties involved in 'scanning' the beam of electrons across the sample. In the SEM, the beam of high-energy electrons is scanned across the specimen, and the current created by the secondary electrons is converted into a signal displayed on a cathode ray tube (CRT). Each new technique opened up new windows on the microstructures within.

The key stage in the evolution of plastics occurred in 1939, which marked the commercial development of nylon. Zone refining, a purification process critical to the development of silicon technology, also emerged in the 1940s. The silicon chip is an innovation that launched the information revolution, for it is the basis of radio, television, telecommunications of many kinds, computers, the Internet,

*Figure 2* **Philosophy of research and development in materials science and engineering**



*Source:* Rohatgi, 1988.

intelligent monitoring and control systems, and a host of other services.

Another prominent development was the introduction of aluminium, both for simple but extensively used domestic utensils and, in a much more demanding role, for aircraft structures, which has made the era of inexpensive mass air transport possible. The main materials development underlying this has been the large-scale electrolytic reduction of aluminium ore using low cost electricity, but improvement of the metal by alloying was also a contributing factor.

The 1950s saw the development of high temperature alloys. Nickel-based alloy developments impacted on jet engine development. In 1955, polymerization catalysts were discovered for polymers, and this opened a way for a new range of plastics, polymers, and synthetic fabrics and also led to phenomenal growth in engineering applications. The development of technology capable of producing smaller and smaller silicon wafers was the major science and engineering achievement of the 1960s.

The 1970s were marked by the emergence of new industries based upon materials processing of recycled scrap iron; mini-mills were developed. Less spectacular, but perhaps even more important, has been the massive production and widespread use of structural steel, again the result of inexpensive production on a truly grand scale. In fact, steel remains to this day the cheapest means of buying sheer tensile strength. Sintering techniques (forming shapes using metal powder) also improved many manufacturing processes. Rapid evolution coupled with the ability to make ceramic materials characterized a good part of the 1980s. Important to note during this time was the development of high-temperature ceramic superconductors.

Another significant development that influenced the future direction of material science and technology was the broad movement towards creating materials that would have greater 'knowledge input' per unit weight. This reflected a strong historical trend among competing industrial countries to develop products with a high added value. Recent advances in materials engineering have been made in such areas as photonic devices for optical computing, forming sheet metal using numerical simulation, explosion-proof electromechanical equipment for anti-terrorism purposes, and nanotechnology – the science of design of materials at a nanometre ($10^{-9}$ m) level.

## ADVANCES AND APPLICATIONS IN DIVERSE FIELDS

Advances in materials science have occurred in many fields: medicine, energy utilization, transportation, and information and communication. Most of these developments have resulted from interdisciplinary research. The following section gives some examples of different materials and their application in diverse fields.

### Materials for medicine

Advances in tissue and organ engineering and repair are likely to result in the development of organic and artificial replacement parts for humans. The field of tissue engineering was born in the 1990s. In addition to organic structures, advances are likely to continue in engineering artificial tissues and organs for humans. Researchers are developing multi-functional materials that provide both structure and function or possess different properties, enabling new applications and capabilities. For example, polymers with a hydrophilic shell around a hydrophobic core (biomimetic of micelles) can be used for timed release of hydrophobic drug molecules, as carriers for gene therapy or immobilized enzymes, or as artificial tissues. Polymers stabilized by sterilizing could also be used for drug delivery. Ceramics such as bioactive calcia-phosphate-silica glasses (gel-glasses), hydroxyapetite, and calcium phosphates can serve as templates for bone growth and regeneration. Biomimetics is the design of systems, materials, and their functionality to mimic nature. Current examples include layering of materials to achieve the hardness of an abalone shell or trying to understand why spider silk is stronger than steel.

### Buildings

Research on composite materials, waste management, and recycling has reached the stage where it is now feasible to construct buildings using materials fabricated from significant amounts of indigenous waste or recycled material content. These approaches are finding an increasing number of cost-effective applications, especially in developing countries. Examples include the Petronas Twin Towers in Kuala Lumpur, Malaysia (Plate 91). These towers are the tallest buildings on earth and are made with reinforced concrete rather than steel. A roofing material used in India is made of natural fibres and agro-industrial waste. Table 8 shows raw materials used in the making of cement – a major component of construction works.

Prefabricated composite materials for home construction have also been developed in the United States, and a firm in the Netherlands is developing a potentially ubiquitous, inexpensive housing approach targeted for developing countries that uses spray-on material over an inflatable air shell.

### Transportation

Millions of cars, trucks and other transportation equipment produced every year consume huge quantities of materials. Therefore the development of lightweight materials for automobiles that increase energy efficiency while reducing emissions is a welcome innovation. Here the key issue is the strength-to-weight ratio vs. cost. Advanced composites

*Table 8* **Raw materials in Portland cement**

*(percentage of total composition)*

| Raw material | Lime | Silica | Alumina | Iron oxide | Magnesia |
|---|---|---|---|---|---|
| Limestone | 52 | 3 | 1 | 0.5 | 0.5 |
| Chalk | 54 | 1 | 0.3 | 0.2 | 0.3 |
| Cement rock | 43 | 11 | 3 | 1 | 2 |
| Clay | 1 | 57 | 16 | 7 | 1 |
| Slag | 42 | 34 | 15 | 1 | 4 |

*Source:* Tegart, 1988.

with polymer, metal, or a ceramic matrix and ceramic reinforcement are already in use in space systems and aircraft. These composites are too expensive for automobile applications, so aluminium alloys are being developed and have been introduced in cars like the Honda Insight, the Audi A8 and AL2, and General Motors' EV1. Although innovation in both design and manufacturing is needed before such all-aluminium structures can become widespread, aluminium content in luxury cars and light trucks has increased in recent years. Polymer matrix, carbon fibre (C-fibre) reinforced composites could enable high mileage cars, but C-fibre is currently several times more expensive than steel. Spurred by California's regulations concerning ultra-low-emission vehicles, both Honda and Toyota have introduced gasoline-electric hybrid vehicles.

## Information and communication

Integrated chips are at the heart of modern information and communications systems. From vacuum tubes to transistors to integrated circuits and optical fibres, the dramatic rise in power systems that process and transmit information has resulted from advances in materials science. The research in *nanoscale materials* – materials with properties that can be controlled at sub-micrometre ($<10^{-6}$ m) or nanometre level – has improved the field of information and communication. The properties of some materials in these size regimes are often fundamentally different from those of ordinary materials. Examples include carbon nanotubes, quantum dots, and biological molecules. These materials can be prepared either by purification techniques or by tailored fabrication methods.

## Self-assembly technology

Self-assembly refers to the tendency of some materials to organize themselves into ordered arrays such as colloidal suspensions.[3] Examples of self-assembling materials include colloidal crystal arrays with mesoscale (50–500 nm) lattice constants that form optical diffraction gratings, a light-emitting diode (nanoscale), a porous metal array (by deposition followed by removal of the colloidal substrate), and a molecular computer switch.

## Rapid prototyping technology

This manufacturing approach integrates computer-aided design (CAD) with rapid forming techniques to quickly create a prototype (sometimes with embedded sensors) that can be used to visualize or test the part before making the investment in tools required for a production run. Originally, prototypes were made of plastic or ceramic materials and were not functional models, but now it is possible to make a functional part, out of materials such as titanium.

## Energy systems

Materials provide particular properties that are required for the conversion, transmission, and consumption of energy. Wood, water, coal, oil and gas are some of the materials that have long been used to provide energy in different parts of the world. An important objective is to lower the cost of energy. Materials advances have contributed significantly in improving efficiency in energy use – for instance in the heating or cooling of buildings, improving reliability and safety and also enabling alteration in the mixtures of the sources of available energy.

Along with investments in solar energy, current investments in battery technology and fuel cells could enable continued trends in more portable devices and systems while extending operating times. Advances in fusion and fission of materials have also led to use of nuclear energy.

## Magnetic refrigeration and other advances

The discovery in the late 1990s of a new class of materials represented a significant advance in the cooling power of materials currently used for magnetic refrigeration. The new materials are made of a gadolinium-silicon-germanium alloy and have two advantages over existing magnetic coolants: they exhibit a giant magneto-caloric effect – the ability of certain materials to heat up when placed in a magnetic field, then to cool when taken back out again – and when used they provide a wide range of operating temperatures.

Advances in glazing materials for windows have led to windows' being more energy efficient while offering increased comfort; these techniques include the use of spectrally selective coatings, absorbing glazing, and reflective coatings.

Other materials advances are being applied in areas such as hot roll laminations in printed circuit materials, passive components (for non-energy generators) in electronics and other mobile components, computer chip-based assets, which enhance security and reliability, and non-destructive testing – a technique that led to safety of products and reduced risk of failure of materials or functions.

## Materials and socio-economic development

A better life and an improved standard of living are the fundamental aspirations of the 70 per cent of humanity living in the poor countries of Africa, Latin America, the Middle East, and South-East Asia, and socio-economic development is a means to achieve these goals. It is estimated that 2 billion people live below the poverty line worldwide. This situation is fertile ground for political unrest. Hopelessness and despair also lead people to immigrate to the industrialized countries in search of a better future.

Materials in the form of mineral resources can generate substantial wealth, but they can be depleted and are non-renewable. For sustainable development, these resources need to be managed in such a way that the wealth they generate can effectively compensate for the depleted mineral assets. Such management is especially important in those countries that are largely dependent on minerals for their economic development. Millions of people are employed in the production of primary materials and many more in the research and development of these materials. Materials are used in energy generation that is very crucial for sustainable development energy. Poverty and living conditions are linked to the way energy is used. Even though there is a

difference in energy use between industrialized and developing countries, the relationship between energy and sustainable development can be seen. Mining activities in different parts of the world where there are mineral reserves consisting of metals like manganese and iron, or non-metal construction materials such as ceramics and refractory minerals, have helped lift the economic status of the people involved in them.

Ceramic manufacturing has become an important industry because of the unlimited supply of clay in some parts of the world. An example is the Užice region of Serbia, where rich deposits of architecture stone and black and dark limestone exist. Biomedical advances (combined with other health improvements) using specialized materials are already increasing human life span in countries where they are applied. This affects issues such as population age demographics, financial support for retired persons, and increased healthcare costs for individuals. Advanced materials, which are normally not the end products, can lead to direct employment of members of society in the production of the primary commodities.

The twentieth century has seen incredible change in industrial countries brought about by the information revolution, based on radio, television, telecommunications of many kinds, and the ubiquitous computer and the Internet. One materials development has made all this possible: the silicon chip. The triumphal outcome of intense research and development of semiconductors means that silicon chips are now made by the millions and constitute the heart of all these information systems. The idea that computers are simple machines only useful for computation has given way to the use of computers for personal productivity with the advent of the microprocessor, thanks to material advances. As the power of these microprocessors has grown exponentially, so have has their usefulness as a vehicle for new media and socialization. Our current technological revolution is often mistakenly characterized as one limited to progress in information technologies. However, the role played by new materials is now becoming increasingly clear – and extends far beyond electronic components and computer hardware. Accordingly, numerous governments have undertaken to define strategies and priority lines of action in order to stimulate materials research and to more efficiently exploit the potential economic benefits of the advanced materials. In many countries these efforts have taken the form of research and development incentives, large research programmes partially financed from public funds, or specific market procurements. Authorities are also creating competitive environments by giving attention to the standard-setting processes, and reducing obstacles to materials diffusion with initiatives that encourage information dissemination, education and training, for example.

## CHALLENGES IN MATERIALS DEVELOPMENT AND APPLICATIONS – A GLOBAL PERSPECTIVE

The materials sector faces multiple challenges that arise from demand for new products with unique performance requirements, demand for improved performance or extended life of existing products, the availability of new manufacturing methods, cost reduction requirements, and international competition. The demand for new products with unique performance requirements can be seen in the aircraft industry, which focuses on the need to enhance basic capabilities including range, payload, speed, and operating cost. New manufacturing methods are needed in the automobile industry, especially because of regulations and competition.

The mining industry causes immense environmental pollution worldwide. Mining operations shift 28 billion tons of material yearly, that is, more than the quantity moved by all the rivers in the world. Mining generates 2.7 billion tons of waste, in part hazardous; an amount that far exceeds the world's total accumulated municipal garbage. Every year mines and smelters account for up to one-tenth of all the energy used by mankind and pump out into the atmosphere six million tons of sulphur dioxide, a major cause of acid rain. The mining industry also adds to land degradation and can be a heavy burden on women and children.

### A concern about exhaustible mineral resources

The increasing use of mineral raw materials since the beginning of the industrial era, and the unprecedented high rate of mineral production development especially after the Second World War, have led to great concern that we shall run out of non-renewable resources. This concern often translates into rapid price increases, along with growing awareness of the need for recycling. In energy production, one of the most difficult challenges in fusion reaction is dealing with neutron radiation for nuclear energy production. Neutrons produced during fusion can travel tens of centimetres out into the containment structure, causing damage to the constituent materials. Also very serious are the health hazards due to inhaling the smoke from biomass fuels used for cooking, especially in the poorer countries of the world. This problem is a major challenge for materials scientists and engineers working in the field of renewable energy. There has been criticism in the press about the use of nickel in some of the new European euro coins. Many people suffer from allergic dermatitis when they come into contact with nickel. Clearly the nickel industry faces a challenge too.

In many cases, one could argue that material developments together with associated computerization and installation of 'smart' manufacturing systems, have contributed to large-scale unemployment. These socio-economic effects also need to be addressed. The great challenge for materials science as far as international development is concerned, will be to increase the availability of materials required for housing, water, food, energy and healthcare by as much as 10 to 100 times in the decades to come, without increasing pressure on resources, energy requirements, the environment and employment. The population of many developing countries will have more than doubled in 50 years' time, and these countries will be trying to attain the standards enjoyed in the rich countries today.

## ENERGY SOURCES AND APPLICATIONS
### *Eriabu Lugujjo*

Since the beginning of human existence, energy has been one of our greatest needs. All our daily activities require energy. This same energy has been harnessed to foster political, economic and social development. The role of energy in determining the economic well-being of a society is often inadequately understood. In terms of total energy, the main energy source for any society is the Sun, which through the cycle of photosynthesis produces the food that fuels and sustains both individuals and populations.

Energy sources are generally grouped into two classes – renewable and non-renewable energy sources. Renewable energy sources are those that are likely to continue to exist so far into the future that they are thought to be unending, e.g. solar energy from the Sun, wind energy, hydro-electric power, energy from biomass and hydrogen, and – in theory, at least – wood. Non-renewable energy sources are those sources that are being depleted, e.g. coal, petroleum, natural gas and nuclear energy from radioactive elements.

## RENEWABLE ENERGY SOURCES

### Solar energy

The Earth is bathed in huge amounts of solar energy. The Sun, a typical star, is a fusion reactor that has been burning for over 4 billion years. Solar energy is our oldest energy source, and all life is maintained by this solar energy that is converted into chemical energy by plants. Humans have always used the Sun's energy directly (e.g. for drying clothes and foodstuffs) as well as indirectly to power the agriculture that supplies us with food. The history of solar energy technology takes us back to 1839, when Edmund Becquerel observed that 'electrical currents arose from certain light-induced chemical reactions'. This was later explained by the quantum theory in the beginning of the twentieth century. The development of the first solid-state devices in the late 1940s paved the way for the first usable silicon solar cell with 6 per cent efficiency. This solar cell had its first application on *Vanguard 1*, the first satellite to use electricity from the Sun. Today solar energy is being used for heating purposes, in homes and industries, and for generating electricity (Plate 92).

### Wind energy

Humans have harnessed the energy of the wind for over 2,000 years. The first windmills were built in Persia and converted wind energy into mechanical power. Until the Industrial Revolution, windmills were used extensively to provide power for many purposes such as pumping water and grinding grain. Wind was second only to wood as a source of energy. Wind turbines are now being used to convert wind energy into electricity. Winds are caused by the differential heating of the Earth's surface by the Sun. Wind is thus an indirect form of solar energy, and is therefore 'renewable'. Every location on Earth experiences wind, but the absolute amount of wind in any one area is highly variable. The average wind speed of a site is a very important factor in determining the cost of electricity generated from wind turbines. This is because the amount of energy that can be captured by a wind turbine increases as the cube of wind velocity (Plate 93).

### Biomass

Biomass is a renewable energy source derived from the carbonaceous waste of various human and natural activities. It is derived from numerous sources, including by-products from the timber industry, agricultural crop residues, municipal and industrial wastes. Biomass is an important source of energy and the most important fuel worldwide after coal, oil and natural gas.

### Wood

For thousands of years since the Stone Age, when our ancestors started the first intentional fire, wood has been the world's most common source of energy for cooking, heating and manufacturing. In fact, it has only been in the last few hundred years – since the Industrial Revolution – that humans have used other sources of energy such as fossil fuels. Many countries in the developing world still use wood as their primary energy source. Half of the energy used on the African continent is in the form of fuel wood. Wood is

a 'ligno-cellulosic' material ultimately formed by photosynthetic reactions within the leaves or needles of trees. Photosynthesis uses the energy of the Sun to take carbon dioxide ($CO_2$) from the air and convert it into organic material, releasing oxygen in the process. As the Sun is the source of wood energy (and all other biomass), wood is essentially a 'renewable' source of energy, which will be available as long as the sun shines. Nonetheless, environmentalists warn us that we may be depleting the Earth's wood reserves faster than nature can replenish this precious resource. There are three basic sources of wood, which can be used for the production of energy, namely the existing forests, wastes from forest products industry, and fuel wood plantations.

## Hydroelectric energy

Hydroelectric power plants convert the kinetic energy contained in falling water into electricity. The energy in flowing water is ultimately derived from the Sun, and is therefore constantly being renewed. Energy contained in sunlight evaporates water from the oceans and deposits it on land in the form of rain. Differences in land elevation result in rainfall runoff and allow some of the original solar energy to be captured as hydroelectric energy.

Hydroelectric power is currently the world's largest renewable source of electricity, accounting for 6 per cent of worldwide energy supply or about 15 per cent of the world's electricity. Traditionally thought of as a cheap and clean source of electricity, most large hydroelectric schemes being planned today are coming up against a great deal of opposition from environmental groups and indigenous peoples.

Hydroelectric power plants capture the energy released by water falling through a vertical distance, and transform this energy into useful electricity. In general, falling water is channelled through a turbine, which converts the water's energy into mechanical energy. The rotation of the water turbines is transferred to a generator, which produces electricity. The amount of generated electricity is dependant upon two factors, i.e. the vertical distance through which the water falls, called the 'head', and the flow rate, measured as volume per unit time. The electricity produced is proportional to the product of the head and the rate of flow.

## Geothermal energy

Geothermal energy is energy recovered from the heat of the Earth's core. In nature, geothermal heat shows up in the form of volcanoes, hot springs and geysers. For thousands of years, humans have used naturally occurring hot springs for bathing. More recently, geothermal energy has been used to generate electricity and to provide heat for homes and industries. Geothermal energy is a versatile and reliable source of heat and electricity, which generally produces none of the greenhouse gases associated with the combustion of fossil fuels. The high temperatures in the Earth's core are a result of heat trapped during the formation of the Earth approximately 4.7 billion years ago, as well as the decay of naturally occurring radioactive elements. Geothermal energy is often considered a renewable source of energy.

This is not strictly true, because human uses of geothermal energy generally remove the heat from a location faster than it is replaced. The magnitude of the geothermal resource is so large, however, on a human time scale, that it may be considered as a renewable energy source.

## Hydrogen

Hydrogen is the third most abundant element on the Earth's surface, where it is found primarily in water ($H_2O$) and organic compounds. It is generally produced from hydrocarbons or water; and when burned as an energy source, or converted to electricity, it joins with oxygen to again form water. Hydrogen is produced from sources such as natural gas, coal, gasoline, methanol, or biomass through the application of heat; from bacteria or algae through photosynthesis; or by using electricity or sunlight to split water into hydrogen and oxygen.

# NON-RENEWABLE ENERGY SOURCES

## Coal

Coal has been used as a fuel since about 1000 BC. Although coal is abundant in most parts of the world, it was not used extensively for fuel until the Industrial Revolution. The transition from wood as the main source of fuel to coal, which occurred at this time, was a result of dwindling fuel-wood supplies and the superior energy content of coal. From that point until the end of the nineteenth century, when oil and natural gas came on the scene, coal was the fuel that drove the Industrial Revolution. Coal was burned for a variety of different purposes, which included heating for manufacturing processes, cooking, mechanical power and transportation (steam trains and ships). Coal is a combustible, black sedimentary rock composed predominantly of carbon. It is formed out of plant matter that accumulated at the bottom of swamps millions of years ago, during the Carboniferous Period. The mining of coal is carried out using a variety of different methods depending upon how close the coal is to the ground surface. The United States, the former Soviet Union, China and India have the largest reserves of coal.

## Petroleum

Crude oil, also called petroleum, has become the world's foremost source of energy, and the backbone of our industrial society since its discovery near Titusville, Pennsylvania, in 1859, by a man drilling for water. Oil accounts for 38 per cent of energy use worldwide (Plate 94). Oil's liquid form, high energy density, and relatively clean burning nature make it the most versatile of all fuels. When oil was first discovered, it was primarily used in the form of kerosene for lamps and stoves. Since that time, inventors have developed hundreds of new uses for oil, the most prominent being the internal combustion engine. Crude oil is a complex mixture of carbon and hydrogen (hydrocarbons), which exist as a liquid in the Earth's crust. On average, crude oil is made up of 83 per cent carbon and 12 per cent hydrogen, the remainder being sulphur, oxygen and

nitrogen. The carbon and hydrogen in crude oil are thought to have originated from the remains of microscopic marine organisms deposited at the bottom of seas and oceans. Crude oil is 'mined' by drilling a hole into the reservoir rock (sandstone, limestone etc.). Often, the oil is under pressure and will emerge from the hole on its own. Once crude oil is extracted from the ground, it is 'refined' into many different products, e.g. gasoline, fuel oil and lubricants.

## Natural gas

This gaseous mixture of light hydrocarbons (including methane, ethane, propane, butanes and pentanes) is found underground in sedimentary rock formations, often in the same location as crude oil. Natural gas, the cleanest burning fossil fuel, is now widely used for space heating and electricity generation. Until the past few decades, natural gas encountered while drilling for oil was often simply burnt off, because the infrastructure necessary to capture the gas and transport it to potential users was not available. Today, natural gas pipelines are in place to serve a large portion of the industrialized world; they supply 20 per cent of the world's commercial energy needs.

## Nuclear energy

Although initially developed for use in weapons, nuclear fission has mostly been harnessed to produce electricity in the second half of the twentieth century. In 1956, in the United Kingdom, the world's first nuclear power station began functioning on an industrial scale, and the first-generation reactors are still operating successfully. These nuclear power plants can be seen as a 'clean' source of electricity because they do not emit the atmospheric pollutants given off by fossil fuel-fired power plants (Plate 95). The nuclear industry has also spawned many different technologies used in medical procedures and industrial applications. Although the benefits from the nuclear industry are great, they are not without risk, for any use of nuclear energy produces some waste that is radioactive and harmful to living creatures. The damage to living tissue caused by the radiation depends on which parts of an organism are exposed and the intensity and duration of the radiation.

## PATTERNS OF ENERGY CONSUMPTION

Energy consumption patterns show a general shift from the consumption of energy from scarce resources to those that show continuity in existence, i.e. renewable sources. The increase in energy demand has also precipitated the need for additional renewable sources of energy. Prior to the invention of the internal combustion engine by August Otto in 1876, mechanized transportation was provided by the steam engine. Steam engines using coal or wood as a fuel were used to power ships and trains; but they were too large and cumbersome for use in smaller applications. The gasoline powered internal combustion engine was able to deliver much more power from a compact design, making it an ideal match for many types of vehicles, including the automobile and later the airplane. At the present time, oil

provides the energy for over 95 per cent of the world's transportation needs. When oil was cheap, it was often used to generate electricity, especially in remote locations such as islands, which did not have access to hydroelectric power or coal. Oil was well suited for electricity generation in such applications because it is easy to transport and store. Today, oil is still used to generate electricity in many of these places, simply because the power plants are already in place. Oil-fired power plants operate in the same way as those fuelled by coal. Oil is burned, producing heat, the heat boils water, and the steam produced is used to spin a turbine. In this type of power plant only about 35 per cent of the energy originally in the oil is converted into electrical energy. The rest is lost to the environment as heat.

Oil was plentiful and cheap throughout most of the twentieth century, resulting in patterns of transportation and land use based upon the private automobile. Oil was also extensively used for heating homes and generating electricity; and since oil was so cheap, it was not used very efficiently. The world's romance with oil came to a crashing halt in 1973, when OPEC (Organization of Petroleum Exporting Countries) unilaterally raised prices and cut production. Oil prices skyrocketed, there were huge lines for gasoline in the United States, and oil suddenly became a political issue. More recently, dwindling supplies in the industrial world and concerns over global warming are also beginning to change the world's oil consumption patterns.

Renewable energy sources are rapidly becoming superior to non-renewable energy sources due to their continuing existence and environmental friendliness. Greenhouse gases like carbon dioxide are not produced by renewable energy sources, but they are removed from the atmosphere.

Renewable energy sources are readily available at a relatively low cost. Thanks to technological inventions like the photovoltaic cells, wind and steam turbines, energy from these sources can be converted into other forms, e.g. electric power. The operation and maintenance costs of such equipment are usually low. A non-renewable energy source like petroleum is the most versatile of all fuels and has found widespread application in the transportation sector because of its liquid form, high energy density, and relatively clean-burning nature. This use of oil in the transportation sector was precipitated by Otto's invention of the internal combustion engine.

## ENERGY, ENVIRONMENT AND DEVELOPMENT – A GLOBAL PERSPECTIVE

The current efficient use of energy from the various sources has led to the rapid industrialization and eventual development of many parts of the world. However, energy produced from the various sources has had both positive and negative impacts on the environment: energy from renewable sources (e.g. biomass and wood) results in no net increase in atmospheric carbon dioxide ($CO_2$), which is a greenhouse gas. This is based on the assumption that all the $CO_2$ given off by the use of biomass and/or wood was recently taken in from the atmosphere by photosynthesis. Increased substitution of fossil fuels with biomass and wood-based fuels would therefore help reduce the potential for global warming, caused by increased atmospheric concentrations of $CO_2$. The current worldwide production

of wood and crop residues for biomass is very large, thus leading to increased use of biomass and wood for fuel. This has led to significant environmental impacts, the most serious being those of lost soil fertility, soil erosion and desertification of the deforested areas. Wood-burning stoves can be a cause of health concerns in both indoor and outdoor environments due to emissions of particulates and carbon monoxide (CO). Elevated levels of CO are associated with a number of adverse health effects including decreased ability to concentrate, aggravation of heart and lung diseases and retardation of fetal growth. The use of fossil fuels has two distinct types of environmental impact. The first occurs during production, while the second occurs at the point of end use. Exploration for oil, oil production and oil transportation all have negative impact on the environment. The heavy equipment required often damages ecosystems in areas of oil exploration and production. The combustion of fossil fuels releases $CO_2$, as well as sulphur dioxide ($SO_2$) and nitrous oxides ($NO_x$), which result in acid rain. Currently, oil directly used for transportation is responsible for about 25 per cent of the world's $CO_2$ emissions. Also the incomplete combustion of oil, coal and wood results in increased levels of carbon monoxide, unburned hydrocarbons and ultimately ground level ozone. All these affect human health and the environment. The final environmental impact related to the production of oil is indirect, and related to the important role oil plays in the world economy. It is an undeniable fact that one of the reasons for high tensions in the Middle East is the value of the oil reserves in that region. It is believed that the main motivation behind the 1991 Gulf War was the world's need for reliable and inexpensive sources of oil. The Gulf War resulted in damage to the marine environment of the Persian Gulf, atmospheric pollution from burning oil wells, and damage to desert ecosystems by tanks and other heavy equipment.

## CONCLUSION

The dilemma of developing energy while protecting the environment may, in the long run, provide human beings with their best chance to reassess some old assumptions and to reorder their priorities for a safer and more pleasant life. Even before these environmental and health problems reach crisis proportions, technology is being developed that would help ensure both environmental integrity and efficient energy production and utilization. However, technology alone cannot be expected to solve problems that may also require political will and a shift in society's values and behaviour. A multi-pronged approach combing new strategies, innovative technology and a desire to ensure sustainable development will be needed.

## ANNEX – ENERGY TECHNOLOGIES AND APPLICATIONS

The development of energy technologies was precipitated by the fear of exhaustion of the present energy sources and need to increase the efficiency of energy use.[1] Solar energy technology started in 1839 with the discovery of the photovoltaic effect; below is a chronology of developments in this technology:

**1839** – Becquerel discovers photovoltaic effect
**1876** – Adams and Day observe photovoltaic effect in selenium
**1900** – Planck postulates the quantum nature of light
**1930** – Quantum theory of solids proposed by Wilson
**1940** – Mott and Schottky develop the theory of solid-state rectifier (diode)
**1949** – Bardeen, Brattain and Schottky invent the transistor
**1954** – Chapin, Fuller and Pearson announce 6 per cent efficient silicon solar cell
**1954** – Reynolds et al. report solar cell based on cadmium sulphide
**1958** – First use of solar cells on an orbiting satellite, *Vanguard 1*.

Solar energy has found widespread applications in rural electrification, electric power generation in satellites, telecommunication and remote monitoring. Energy from other sources like wind, biomass, petroleum, natural gas, and hydrogen is largely being used for the generation of electricity using wind, water and steam turbines, and generators. This generated electricity is then distributed to the different consumers using grid networks.

## CULTURE AND COMMUNICATION
## TRADITIONAL MODES AND NEW TECHNOLOGIES

---

*Judith Mbula Bahemuka*

### INTRODUCTION

At the dawn of the twentieth century, Africa was caught up in rapid cultural change that found expression in different forms of communication. Traditional modes of self-expression, self-identities and cultural images were immersed in new ways of self-actualization, new communication channels, and a new search for technology, which would respond to the everyday needs of the African people. The traditional image of a young Masai long-distance runner, delivering a telegraphic message to a distant village, became a powerful tool for bringing together the old and the new. The latter was the new way of communication, the Masai runner depicted the traditional mode of communication systems.

'Culture and communication', just like 'tradition and modernity', are vast areas of research. The four key concepts in this chapter, namely: *culture, communication, technology* and *modernity*, are contested in social and human sciences. For the sake of focus, we shall restrict ourselves to a discussion that critically analyzes the concepts as they relate to contemporary social and human science theory as well as socio-cultural practice in Africa and East Africa, in particular.

Kress[1] sees a persistent tendency to separate the study of communication from that of culture. He contends that it is difficult to talk about communication independent of cultural settings. For him, 'culture is the domain of meaningful human activity and of its effects and resultant objects; communication is the domain of the intended or unintended exchange of meanings between social/cultural agents'. The processes of communication produce meanings, whereas cultural production brings in meaningful objects; the concept of meaning, Kress asserts, inextricably links these two concepts.

Another relevant argument is from Bradford,[2] who reiterates that communication is the 'foundation of all communities'. This appears to put communication on a par with culture, for one can convincingly say that culture is also the foundation of all communities. The twin themes of culture and communication are discussed in the context of that which is traditional, and the question of modern technology. A discussion of the controversies that have arisen as to what is African and what is universal in the area of both culture and technology is highlighted.

### THEORETICAL ARGUMENT

Models of cultural change, communication, and technology adoption are in agreement that there is no clear distinction between the 'African way of life' and the 'modern world'.[3] Studies by Van Tate, Mbula, and Gyekye[4] show that there are different levels of cultural interaction, and that each of these interaction levels calls for a distinct mode of communication and expression. The argument is that communication is at the core of the African 'persona'. Cultural change, at its best, is to be experienced at the periphery, where communication is by word of mouth, a song, a dance, art, or simple gesturing. This level of cultural change occurs without far-reaching ramifications. Communication, however, is more complex when one is dealing with African themes and institutions. Mbiti argues that the African individual is the personification of the past (the ancestors), the present, and the future (children yet to be born) and that these three dimensions are in constant communication.[5] He gives the example of the cultural practice of pouring out a libation when Africans perform cultural rituals. This form of communication touches on the philosophy and the belief systems of African communities, and the individuals who are involved in this intra-communication.

A further argument is the role of *zamani* (receding past) in African understanding of culture and communication. Ngugi-wa-Thiong'o walks the thin line between that which is traditional and the modern.[6] This dichotomy of the past and the *sasa* (now) belies the deep-rooted search for an understanding of the two dimensions in technology transfer.

Similar observations were made in 1973 by Bretton, who presented African rural villages and the urban centres as two different worlds that had no connection. It is now widely accepted that one cannot draw a clear distinction between tradition and modernity. Among the indigenous

groups like the Masai of East Africa or the Sun of the Kalahari Desert, contemporary lifestyle is a hybrid of traditional cultural practices *communicated* across generations and 'modern' forms of life, for example schooling and public transport systems.

## COMMUNICATION AND CULTURE IN AFRICA

Kunczik defines culture as 'that complex whole which include knowledge, belief, art, morals, laws, customs and any other capabilities and habits acquired by man as a member of society'.[7] This definition, however, omits the fact that culture is largely a function of technology and social change. It is a dynamic way of life whose constancy is that it never ceases to change, picking up certain social aspects, while at the same time shedding others. A diagnosis of African societies from the 1950s to the present shows that although cultural boundaries and distinctions among various groups still exist, there have been rigorous processes of exchange at different levels.

Culture and communication are crucial to Africa as it is mainly in these two processes that human development is embedded. Socio-economic and political development is a result of social change, which is an outcome of diffusion of information and technology. There are, however, some negative aspects through which African cultures are distorted. The glorification of Western values has tended to dispossess Africans of their cultures, thus disempowering them. This is due to the fact that in communication, there is power. Whoever has the knowledge, he/she has power over the person to whom the message is being communicated.

African scholars, poets and statesmen have responded to the power game with vehemence. The very variety and force embodied in the following ideas demonstrate clearly that African culture can respond to any power game from any part of the globe: African Personality (Leopold Sedor Senghor), Humanism (Kenneth Kaunda), Ujamaa (Julius Nyerere), Common Man's Charter (Milton Obote), Harambee (Jomo Kenyatta), Pan-Africanism (Kwame Nkrumah). The writings of Africanists Chinua Achebe, Okot p'Bitek, Ngugi wa Thiong'o and Bolaji Idowu all point out that both communication and culture in Africa can be traced to the core African values.

Culture and communication in Africa are faced with another problem. While scholars argue that African culture has been a barrier to faster economic, socio-political development, there is a counter argument that it is the ignoring of African values and belief systems and wholly adopting modernization paradigms in their place which has led to failures in socio-economic development. A critical analysis of Africa's economic and political problems reveals that African cultural practices are hardly to blame. Whereas Fraser and Restrepo-Estrada argue that for any form of development to be realized there has to be behavioural and attitudinal changes which are attainable through communication, they underscore that ignoring a peoples' cultural practices and values is a sure way of failing in development initiatives.[8]

Closely related to communication and culture are the agents through which communication takes place. The primary agents of communication are the parents and extended family. As one grows older, the peer group, the school and religious institutions step in to augment the work of the family in transmitting skills. Delanty argues that although schools and universities are seen as agents of modernity, they also nurture the dominant and emergent culture models of society. This has been powerfully expressed during the annual music festivals in Africa, where schools, colleges and universities participate to articulate cultural values through modern music. Through music, dance and poetry, powerful messages are communicated on how the past is always present in everyday African life.

Sutton argues that since each individual has a different past, the interpretation of the present is also different.[9] This is what makes agents of communication crucial in helping to understand and interpret each changing situation.

## PERSISTING TENDENCIES

The theory of cultural lag is often utilized to explain why people hold on to old practices. The lag is rooted in the tendency of societies to encourage each new generation to remain loyal to values and behavioural patterns that previously served the societies. Other arguments show that a cultural lag also exists within the moral and emotional domains, thus necessitating a delay in the techno-scientific, socio-economic development. This lag can have a negative impact on a community's attempt to modernize communications systems.

Related to cultural lag is the reflectionist argument that a society's institutions reflect its culture. This means that the type and level of communication should be a reflection of the dominant culture. At times, a combination of cultural elements may exist which, if utilized systematically, could bring about cultural evolution.[10]

Lerner and Schramm brought to the fore the complexities of culture and technology communications.[11] Using a simple model to depict the different channels of communication, they argued that the source, the message and the effect of communication are critical. What core values does the source of the message hold and do the values tally with those of the receiver of the communication? In case of a conflict of interest within the source and the receiver, what outcome does the community anticipate?

Lerner's model of communication helped communication strategists to argue for technology transfer from industrialized countries to Africa, especially to rural communities. This model, however, can only be applied if public attitudes towards support for and understanding of the importance of communication and technology are positive and independent of outside influence. The cultural legitimacy of communication, the value the community places on self-actualization, the reward for individual initiatives and self-reliance all play a critical role.

Cultural lag and communication models will not suffice unless they are seen against the backdrop of technology adoption and the diffusion of ideas. The diffusionist school argues that adoption of technology is achieved in different stages. Individuals and communities who have been exposed through media or other communication channels tend to be the early adopters. These are individuals who are high achievers, often driven by ego needs. The late adopters, who in most cases are the majority, lag behind due to lack of information, the complexity of the technology in question,

its affordability and applicability or the method used to present the technology.

A number of theories about how innovations are diffused have been utilized over the years to explain why Africa has lagged behind in technology adoption. What seems to have escaped people's attention is that communication and innovation have to be seen within a cultural context. The African adopters of technology tend to respond to their immediate needs. They have values, norms, aspirations, expectations and priorities. These drive their perceptions and give them leverage in the choices they make.

The impact of pandemics such as HIV/AIDS, political conflicts, ethnic animosities, international terrorism, extreme poverty, cannot be ignored when dealing with culture and communication. The main dimensions of culture are distance from power, avoidance of uncertainty, and collectivism. These dimensions are, however, problematic. In the case of the HIV/AIDS pandemic, the whole plethora of beliefs, the question of stigma, are embedded in culture. These are critical to both inter- and intra-personal communication on the different ways of dealing with the pandemic in Africa.

Risk-taking is another aspect of culture, communication and technology adoption. Schouten argues that uncertainty avoidance is a complex phenomenon.[12] It is a dimension that indicates people's need for predictability, and shows the extent to which people and communities are willing to take risks.

For an individual to take the risk of adopting a new technology, such motivating factors as the presence of a conducive environment, tangible benefits and upward social mobility must be in place. The argument that Africans are not risk takers finds no support in the social realities of Africa and African behaviour. Communication technology, however, goes beyond these obvious benefits and reaches levels where the intrinsic value of information comes into play.

## TRANSPORT AND COMMUNICATION[13]

The transportation systems in sub-Saharan Africa are plagued by cumbersome administrative and structural impediments, lack of appropriate maintenance and inappropriate policies for managing and regulating services. These problems hamper the efficiency of the systems as well as their economic productivity and the flow of goods and services. As a result, transport costs and delays are the highest in the world. For land-locked countries in Africa, the costs are even higher and are estimated at over 70 per cent of the cost of transit goods.

Another characteristic of transport and communication is the poor inter-connectivity between and among African countries. This is due to the absence of trans-border infrastructure, the existence of different structural and regulatory systems, low inter-country contacts and perceived differences arising out of Africa's colonial history.

The structural gap in infrastructure constitutes a serious handicap to economic growth and poverty reduction. In East Africa, the colonial powers built the infrastructure to facilitate the exploitation and exportation of raw materials and the importation of consumer products into the countries. Therefore, some of these systems do not meet the current conditions and aspirations of the African people.

Improvement of communication infrastructure would lead to the free movement of goods and services/persons. For communication to play its role and have the desired impact on the development of Africa there is a need for: physical and operational integration of networks, convergence of regulatory policies, harmonization of standards and measures, cross border operations and investments and the political will of African leadership.

The quasi-government enterprises, established at independence to run communication infrastructure, have been an obstacle to development. They are, in most cases, suffering from severe financial constraints and corrupt mismanagement, and lack the necessary strategic planning and human resources. To surmount these impediments to developing the communication infrastructure, more is required and especially financial resources, and the exploration of new and innovative initiatives. These could include private sector and community participation, the promotion of intra-Africa trade and contacts through regional integration, and the adoption of business oriented management of infrastructure.

In recent years, progress has been made in enhancing the communication infrastructure in the framework of regional integration. Examples of initiatives include cooperation in road and rail network systems, regulations and standards, the creation of regional telecommunications entities, and liberalization of air transport. However, the achievements made are still modest and more will be required to meet the necessary standards. In addition, the initiatives taken through sub-regional integration risk creating isolated and unsupported infrastructure networks in Africa unless there is a continent-wide push for inter-connectivity. Previous efforts of the Organization of African Unity (OAU) through the various Plans of Action have not been fruitful. However, there is hope, with the launching of the African Union (AU) and the New Partnership for African Development (NEPAD), that both communication and new models of technology will be enhanced.

## THE GLOBAL DIMENSION

Globalization is seen as an irreversible socio-economic, political and cultural reality that does not create a unified global culture, but rather sets the stage for global differences.[14] However, the irreversibility of the globalization process has an impact on the relationship between communication and culture at the local level, shrinking the world and promoting the emergence of a 'global village'.[15] Globalization implies a departure from a traditional local way of understanding issues through a national perspective to a more accommodating global view. In orthodox anthropology and rural sociology, a traditional worldview is characterized by archaic ideas, indigenization of knowledge, narrow-mindedness, and adherence to customs and cultural norms. Based on this thinking, Robert Redfield came up with the folk–urban dichotomy.[16] This distinction would signify that globalization is a shift from the traditional village communication mentality to global thinking.

The polarization of traditional and new communication technologies is not tenable since many features of traditional channels of communication are carried on via the new channels. What seems apt is that a shift from traditional to global produces a continuum where individuals, communities

and nations are placed at different levels along the technology path. As such, African countries may be seen as ranking on the lower end of the technology continuum than the new industrialized countries while the developed countries rank highest. Within this differentiation there is interdependence among the different actors as is evident in the world system theory where it is inevitable that the core cannot do without the periphery.

## NEW TECHNOLOGIES AND COMMUNICATION FOR CHANGE

The question of whether or not Africans can participate in the generation of knowledge and in applying it to solve Africa's technological needs is not only critical, it is urgent. However, the talk of 'new technologies' raises fundamental issues – notably the question of time and space/context. Some technologies considered 'new' in Africa are old or irrelevant elsewhere. Furthermore, Africans have not been mere consumers of foreign technology. They also reject what is new or modify it to suit their own needs. Africa's 'informal sector', where all manner of affordable metal gadgets are made, attests to an entrenched culture of technology. Like the blacksmiths of the past, the contemporary African artisans are innovative. They operate their Kiosks in the *jua Kali* (hot sun) and produce communication tools which are accessible and affordable to local communities. Where necessary, they modify mechanical and electrical equipment or use it as a model to produce what suits local needs and levels of income. In other cases, some of Africa's indigenous technologies like the artistic 'Makonde' woodcarvings from the United Republic of Tanzania, and arts and crafts from Kenya and Benin, have found space on many shelves around the world.

The emerging knowledge societies are not a new phenomenon. Indigenous technical knowledge in Africa has served local communities over the years. The provision of distance education through the Internet to the Masai of Kenya or the rural populations of Senegal (University of Massachusetts Project 2002) is a response to a need for lifelong learning. The Internet is providing people an opportunity to reach out to the global village. Responding to the Internet explosion is the challenge facing rural communities. The infrastructure is inadequate, and yet United Nations Secretary-General Kofi Annan argues that it is indeed in places where infrastructure does not exist that Wi-Fi can be particularly effective helping countries to leapfrog generations of telecommunications technology and infrastructure and empower their people.

The sentiments expresses by Kofi Annan highlight the centrality of information technology for the construction of knowledge societies. New technologies have, however, to be flexible so as to be utilized hand in hand with traditional knowledge.

In the area of technology communication, sub-Saharan Africa consists of countries in transition. Economically, they aspire to industrialize, while politically, more democratic institutions and practices are evolving. These countries are at a crossroads, caught between 'Western culture' and what is branded 'African' perspectives.[17] Due to the deep-rooted notion that what is foreign or Western is best, many Africans often do not regard indigenous innovations as new. An example would be the African herbalists who come up with new medicines but who find few people to adopt them; and those who do, usually do so due to inability to afford what is perceived as better alternatives dispensed by chemists.

## ADOPTING TECHNOLOGY

A closer look at African societies over the last 50 years shows that as society progresses and new technologies emerge, there has been a change in the way people communicate and pass on information. Many urbanized Africans today have an email account, and cyber cafes are found in many urban neighbourhoods. Communication through email within Africa and without has become an everyday occurrence so that sending fax messages has been reduced drastically and, as in the West, fax machines are almost obsolete. Despite the fact that only a few Africans enjoy these services, it would be naive to argue that only a small proportion of Africans lead a culture of technology.

To a large extent, Africans have not simply switched from traditional modes of communication and technologies to new ones. Apart from the disparities in the level of adoption, most actors are at certain points of transition; there are no pure traditionalists or modernists. And in many cases, modernity enhances tradition and by extension, indigenous knowledge. For instance, public transport systems and mobile telephones have become useful among Africa's pastoral groups, assisting them to identify sources of water and pasture as well as locating stolen or missing livestock. External interventions have often adopted existing practices to enhance effectiveness and sustainability of implemented projects. Micro-finance enterprises in Africa which enjoy the support of the World Bank and bilateral agencies often prefer giving credit to groups where each member acts as the other's guarantor, thus providing a social control mechanism (a good example would be the Kenya Rural Enterprise Programme, which has been transformed into a bank). This kind of arrangement, which works relatively well, is rooted in traditional values of reciprocity, mutual social responsibility and accountability.

Another case where the traditional blends with the modern is the Rehabilitation of Earth Dams in Eastern Kenya, a programme funded by UNESCO. Local communities are being given information on international standards of water and sanitation. However, the local women's groups continue to believe that the female water goddess Kathambi preserves the hills that supply the streams with water when it rains. In addition, the leaders of Kathambi demand that the impermeable wall of the sand dam should provide a small hole to allow water to trickle downstream. The argument is that if there is no hole to allow water to trickle down, the people, animals and environment downstream will suffer.

Thus while modern technology in the construction of water dams is concerned with lateral and backward recharge in the river channel, the indigenous people are concerned with the community values of sharing both water and technology. The dichotomies of new and old, traditional and modern, global and local are tools for theoretical arguments. The reality in most of Africa is that the continuum is enriched by the interaction between the organization and the source of information, the communication channel, and the adoption of the technology.

# RE-ENGINEERING AFRICAN TECHNOLOGIES

This chapter is an argument for communication of technology in Africa. This is discussed along a continuum running from traditional communication to modern systems. The nagging question is whether there is any technology that can be termed modern and how long it maintains its newness. In the early 1950s, when most of Africa was struggling with political independence, communication of technologies was localized but was found to be effective and efficient. During this period, Africa achieved, against all odds, major strides in democratic development, and political independence attests to this. The simple technologies, the infrastructure, the channels of communication, worked in harmony for the common good. New technologies, though far advanced and faster than traditional systems, have neither relieved Africans of poverty, nor responded adequately to development needs. This explains why there is an urgent need to re-engineer traditional technologies that have served the people well over the centuries. One positive move came towards the close of the twentieth century, when African leaders, led by President Thabo Mbeki of South Africa, started arguing for an African Renaissance. The move to reclaim African values, to rediscover the values of the people, their artistic contributions, the resilience of communities and the people's capacity to respond to harsh environments is not only challenging but heart-warming for Africanists. The radio, the fax and now wireless communications have taken Africa by storm, but they are no longer new. Radio is one mode of communication that has permeated life in rural communities in Africa. It is the medium through which governments communicate with the citizenry. In a rural African village any 'news' is likely to have been transmitted by radio and then spread across the ridges and valleys through word of mouth, marking again the interaction between the 'new' and the 'old'.

The re-engineering of technologies means that Africa has to look at what has best served the African communities. An example concerning village banks, given earlier in this paper, can be used to show how international banking could set down roots in African wealth-saving systems, and the need to support communities' initiatives. Taken together, the management of the village banks, the levels of communication and the villagers' coherent articulation of their financial needs, put forward a strong argument for re-engineering traditional financial savings and similar technological institutions.

The global landscape presents a challenge to efforts at re-engineering. Africa does not act in isolation. Whatever happens in East Africa will impact on the rest of Africa. This interconnectedness of countries means that there must be sensitivity in the way that one deals with externalities. The market transactions between the producer, the seller and the buyer of farm products have to be situated, the level of communication agreed upon, and the type of technology presented has to be affordable.

New 'foreign' technologies may at times be alienating to the African people. The digital divide is already a big issue. While a segment of society is concerned about the digital divide, it is imperative also that we become sensitive to the priorities of the people. These priorities will help the majority of African people to surge forward and adopt new technologies or innovate their own. What is at stake is the combining of traditional and new communication strategies to support the emerging initiatives and create a synergy that allows Africans to participate in the global arena.

# THE SOCIAL CONSEQUENCES OF SCIENTIFIC AND TECHNOLOGICAL KNOWLEDGE AND PRACTICE

*Dominique Ngoïe-Ngalla*

The relentless efforts of the West – with its roots deep in the eighteenth century and its unquenchable thirst for knowledge and discovery – to know and transform nature have not been in vain. It is fair to say that these efforts, made in all fields of knowledge, have been amply rewarded over the past 200 years (indeed increasingly with each generation) and particularly in the astounding twentieth century. In certain areas of research such as genetics, transport and information, progress has been breathtakingly rapid. Researchers and scientists have recapitulated the theories and findings of the preceding two centuries and subjected them to the requirements of a new epistemology and a new rationality. This has opened up an era of unprecedented scientific progress and technological innovation with tremendous social consequences in the fields of economics, politics and culture. All aspects of social life are being affected by an irreversible drive to destroy and restructure from top to bottom. Quite clearly, a civilization is dying and a new one is rising from its ashes and developing with such speed that, in a few decades, our current civilization will seem to belong to a bygone age. And there is every reason to believe that the transformations taking place – be they magnificent and precisely as we had hoped or obscure and disquieting – are only just beginning.

This future, which is almost upon us, this age-old dream of humanity, will probably be perilously complex, since the sciences and the technologies that embody them are raising very disturbing questions, for which we often have no reassuring answers at present. In a world of unprecedented political instability, will we be able to come to grips with and control such a future? Given the uncertainties of a world that is wholly in the power of a science that seems to raise more problems than it solves, both calm optimism and deep pessimism would be irresponsible attitudes. Science is the only weapon with which we can confront our future in all of its diverse forms – demographic, economic, political, cultural and social. It can be our salvation or it can lead us to our doom. And for as long as the history of humanity continues, this is how things will be.

With such an accumulation of extraordinary scientific knowledge and know-how, and prodigious technological innovations introduced at an increasingly faster and frightening pace, the twentieth century seems to have fulfilled Descartes' prophecy: 'Man as master and possessor of nature'. There is, in fact, not a single field of human knowledge and practice that has not been explored by science and technology, and as a result of this scientific scrutiny, our ideologies and our old representations of the world and our relation to it have been overturned. The epistemological revolution of the twentieth century, which concerned every field of knowledge – physics, chemistry, mathematics, the agricultural sciences, the life sciences, transport and communications – brought about social and sociological changes on an unimagined scale.

Let us take the example of politics, said to be the most effective means of changing our lives. Politics entered the twentieth century on a fast-moving current of profound change, responding to the economic and social upheavals brought about by science and its technological applications. The most striking example certainly remains the terrible confrontation of capitalism and communism, ending with the collapse of the latter under the growing pressure of liberal economics and democracy. Even in the countries where liberal democracy was already present, it was continually being redefined and restructured in response to the demands of an ever more enlightened public and a better-organized populace. Liberal democracy was continually searching for a new political, economic, cultural and social rationale capable of responding to the ever-growing demands of modernity. Its impact on the entire world has been undeniable. Under its impetus a true wind of freedom is blowing around the world, which, despite differences of political regime, is more and more being caught up in the mesh of the economic system of the liberal democracies.

The pressure and the demands of the new economic and commercial forces have gradually broken down the resistance of states, even totalitarian ones, and led to the interconnection of economic and commercial interests the world over. Known by the simple term 'globalization', this extremely complex phenomenon has resulted inevitably from the advances in the field of communication. It is the economy of the global village, which is not without international political implications, since economics is never unaffected by politics.

The multinational companies, which seem to abide by their own laws and can stand up to any government on political issues, have brought all their weight to bear here. Soviet *perestroika* and the collapse of the Berlin Wall would be inexplicable without the pressure brought to bear by the capitalist regimes of the West and the multinationals.

Economics is the driving force behind everything. The sovereignty of states (the exercise of authority on their territory and the right to the monopoly of that authority) is challenged by the fact that there now exists a World Trade Organization (WTO), which has wide powers over states in the area of trade. In addition to the WTO, international law and international justice, whose decisions prevail over those of local courts, further limit the sovereignty of states.

And let us not forget international legislation on human rights! International treaties and the United Nations prohibit states from doing what they please with the lives of their nationals, prohibiting genocide, torture and massacres. Thus the globalization of the world's economic interests, unimaginable without the progress of science and technology, is compelling all states in the world – over and above their ideological and political divergences – to maintain relations based on a consensus about non-negotiable, universal values such as equality of the sexes and racial equality, a need justified by the brotherhood of all men, born equal and facing a shared future. The old order, as we can see, has entered upon a process of drastic change unlikely to be halted by the attendant identity crisis in the cultural and political spheres. In this general commotion, which reflects a fierce desire for a better life, the return to identity is merely a weapon, the signal that justice has often been sacrificed in the name of the law.

## THE STRICTLY SOCIAL FIELD

The changes that have occurred in the strictly political field are simply the consequence of the upheavals in the economic system and the social order brought about by science. If society is regarded as the way of life of an organized body of individuals, economic transformations have drawn it into a process of change on such a scale that one has to call it a revolution. This revolution marks a complete break with the preceding age in regard to standards and systems of values, morals and attitudes, with increasing importance attached to comfort and pleasure. A new civilization is coming into being, a civilization celebrating the body and striving to improve the social and material environment.

In the countries and regions of the world that have given themselves the means, development has become a reality, enabling them to realize the age-old dream of humanity. Civilization, defined as an environment of technical facilities in which people can meet all their needs in respect of health, housing, clothing, food and leisure activities, has become far more accessible to people of the developed world. In a few decades, the social scene, particularly in the West, has undergone a metamorphosis. In an increasingly urbanized society, people are better fed, better housed, enjoy better health care, have improved access to education and culture, especially as the authorities endeavour to give opportunities to all, rich and poor, city and country dwellers.

As a result of the fantastic development of communications and the media, the volume of exchanges and of interaction between people is continually growing. With distances so remarkably shrunk, the Earth is being reduced to the size of a big village where everybody knows each other. When all is said and done, people are clearly leading incomparably easier lives than their ancestors did for thousands of years. With increasingly powerful means, what limits are there to what we could achieve or how far we could go? The exploration of space and the Moon landing confirm the boundless power of human genius and foreshadow still greater exploits to come. This is what lies ahead for the countries known as those of the North, the most highly industrialized and thus the richest in the world – the United States, Western European countries, Australia, Japan, Taiwan, China and Singapore. These countries' human development indicators (HDI), gross national products (GNP) and gross domestic products (GDP) are incomparably higher than those of the largely unindustrialized countries of the South, or the Third World. A study by continent shows, for instance, that 92 per cent of the world's GDP is concentrated in Europe, the United States and certain Asian countries such as China, Japan, Taiwan and Singapore.

The contrasts between the two extremes of civilization are no less striking when average purchasing power and per capita income are taken as criteria. It is clear that at the present time, only a small portion of the globe has benefited from science and technology, which are thus still a long way from having solved all the problems facing humanity (in fact, they appear to be raising many more). There is a reverse side to progress, which requires people to show greater wisdom and to make better use of science and technology if they wish to avoid disaster. If we want nothing but amazing development tools, science and technology could become a terrifying Pandora's box.

## THE OTHER SIDE OF PROGRESS

Such a sudden concentration of tremendous power and means in the hands of people who are ill-prepared and liberated from discredited moral and religious taboos does not occur without serious risks, since the sense of duty required to cope with the new social codes has not kept pace with science and technological innovation. Having become a true demiurge (and very much aware of it), humanity has begun to show that it will not always keep to the boundaries, especially since it must now define what is licit and illicit as pertains to ethics and morals.

In the field of biology, for example, the discovery of DNA, while contributing in a beneficial way to medicine, criminal investigation, justice, etc., tempts the scientist, who is freed from metaphysical or religious taboos and prohibitions, to proceed with a certain kind of genetic engineering that could have dire social and human consequences. To confine ourselves to a sector in which genetic engineering is on the face of it unlikely to raise philosophical or ethical problems, the genetic modification of foodstuffs, the genetic modification of foodstuffs and living organisms, including transgenic plants and animals (those modified by recombinant DNA methods) has already become, in many quarters, a controversial issue with far-reaching economic, social and political repercussions. This contentious issue demonstrates that genetically modified organisms expose humanity to many aberrations and many risks if barriers are not raised.

However, now that science has become a kind of divinity or an absolute domain pursued for its own sake rather than a means of action, its fascination and attraction is such that it is hard for people not to break religious and moral taboos, the justification for which they alone can establish now that many believe that God is dead. With just the light of reason to guide them, who will now forbid scientists to pursue a discovery unlikely to be of benefit to humanity? With omniscience, or the arrogant illusion of it, there is a very great temptation to stop at nothing, the limits of what is possible now being defined by the scientist alone, with God or morality no longer in the picture to set limits. 'Aspire not to the eternal, oh man, but exhaust the field of the possible.' This invitation to excel oneself by an atheist poet freed of all taboos is the only counsel heeded by some modern scientists.

However, new knowledge and technological innovations are continually appearing to exhaust the field of the possible and stimulate the obsessive pursuit of knowledge and know-how towards an ever-receding horizon of unknowns. At the present increasing rate of scientific progress, the most revolutionary technological innovation remains so only for the short space of time it takes for another to supplant it. Consider the explosion of communication technologies between the 1970s and the 1990s, with the computer, the microchip, then the Internet. It all happened so quickly! This endless and constantly accelerating progress is giving rise to new forces, new rationales and new frames of reference in the economic, social, cultural and political spheres. Nothing is stable any more. Today, humanity is facing an unprecedented crisis of civilization, which is systematically challenging the principles and standards on which the world of the past relied. Our survival thus now depends on our capacity to devise other principles and other standards, other rites of passage, for a transition that is likely to be turbulent.

If humanity does not hold on to some kind of wisdom value system (yet to be devised) to protect itself from the threats and dangers to which its own industries expose it, this may constitute a threat to its survival in a world made dubious about its future direction by the headlong progress of science and technology. Many natural disasters such as droughts and floods have occurred. Many disastrous ecological disturbances have also occurred (the famous hole in the ozone layer and the greenhouse effect), and the atmosphere is said now to contain 25 per cent more carbon dioxide than it did before the industrial era. In the absence of any realistic answers or effective countermeasures, such changes could have far-reaching consequences in the short term, e.g. climate change with 1–4 °C temperature increase and a rise in sea levels. These are all nature's brutal response to the failure of humanity to conform to the standards that link it to nature. They are a response to the sluggishness of humanity to fully comprehend the dangers that modern science enables it to foresee. Crises, with their characteristic instability and rift, are to be dreaded since they can lead to regression if people do not take carefully thought-out action. With the increased means for action at our disposal, the wise course in the case of a crisis such as we are experiencing would be to awaken to our human vocation and act accordingly, moderation in all things remaining the great normative principle on which individuals must set their lives and their action.

Unfortunately, the flood and clutter of the material aspects of post-modern industrial society are distancing people from this rigorous ethical principle and leading to a disorderly and hedonistic consumer society. Today's consumer society is striving to achieve a veritable subversion of the established order. The slogan of the new ethic is: 'Down with boredom! Enjoy life unfettered!' When it comes to eating or drinking, everything has become immediately accessible providing that one can pay. Similarly, in the field of the libido, there are no prohibitions or taboos. Humans are in a way reinventing the world as a world for which they are entirely responsible, thereby lending credence to the notion held by some Westerners that God is dead.

Growth is the reference point of the new economic and social system. Its prime objective being to achieve a steady increase at all costs in production, incomes, employment and investments, it gives rise to a hedonistic society in which the requirement to continually create new needs is met by the obsession to enjoy and to consume. A spend-and-waste type of capitalism is replacing the work and thrift capitalism of the nineteenth-century middle class. The result is an incapacity to act in accordance with one's values – abhorrence of slavery, emancipation of the whole of humanity, and solidarity with the most deprived. The aid provided by the wealthy countries is insufficient. Some of these same countries provide support for Third World despots who sometimes end up as their henchmen in the exploitation of barely subsisting populations. Nearly 1.3 billion people are living in absolute poverty, and every year 40 million die from hunger-related illnesses, which could quickly be eradicated with good will. At the global level, it is not a question of insufficient production, but of poor distribution of food resources. Malnutrition in the world is thus one of the least excusable injustices, and the assistance provided by wealthy countries is clearly insufficient.

## THE WIDENING GAP BETWEEN NORTH AND SOUTH

A comparison of the HDI, GNP and GDP of developed and Third World countries reveals differences that leave one perplexed. Given the recurrent disorder in which most Third World countries are mired, together with their heavy indebtedness (the total they owe to the countries of the North exceeds the value of the aid that the North grants to them), the gap will probably never be closed. At present, it is widening and will not be narrowed by the current growth patterns and constraints of the economies of the North. For things to be otherwise, the Third World countries would have to receive steady, better-conceived and more generous assistance from the countries of the North by means of a kind of Marshall Plan. Unfortunately, owing to the egoism of the affluent countries, it will not be easy to set up such a plan for a long time to come. The countries of the North already find it hard to keep up with the United Nations, which asks them to set aside just 0.7 per cent of their GNP for development aid for the poor countries.

Moreover the HDI, GNP and GDP of rich countries would probably not be at their current level if the poor countries did not supply their industries with raw materials at such low cost. For this reason, rich countries keep a watchful eye on the poor countries that possess strategic raw materials such as gas, oil, manganese or uranium.

*Table 9* **The gap between rich and poor countries**
*(per capita GNP expressed in US$)*

| Country | per capita GNP |
|---|---|
| Luxembourg | 41,866 |
| Ethiopia | 105 |
| Switzerland | 41,411 |
| Mozambique | 100 |
| Denmark | 29,890 |
| Sudan | 270 |
| Norway | 31,250 |
| Chad | 179 |
| France | 24,990 |
| Burundi | 160 |
| United States | 27,647 |
| Malawi | 189 |

The development and the comfort produced by science and technology have not really uplifted the human mind to a more humane attitude. There is extreme poverty in the world, and it is growing even within the Western world, where the existence of pockets of wealth and unprecedented material abundance does not prevent more than 10 per cent of the population from suffering from poverty. It is also in the West that some persons who have become unemployed as a result of the increasing robotization of some sectors of industry or the decline of agriculture in favour of the industrial sector, end up homeless, abandoned to their own resources, and find themselves in a situation of physical and moral degradation unknown to even the poorest inhabitants of Third World shanty towns. All things considered, poverty in the rich countries is negligible and not so alarming compared with that of the developing world. In Third World countries given over to unregulated exploitation by the wealthy and major powers, poverty and destitution, glaring and unending, are incommensurably worse. None of this is new, of course, but with the advent of globalization and mass tourism it has assumed an extraordinary worldwide dimension. Drug trafficking and prostitution, taken over by powerful networks of organized crime, are born of poverty and destitution. The countries concerned are naturally the poor countries of Africa, Asia, the Caribbean and the former Soviet republics in Europe.

The loosening of the bonds of solidarity that are a hallmark of well-integrated, hierarchized and ordered societies is a manifestation of modern society's rejection of the values that it has considered fundamental until the present time. Modern egalitarian society, with its faith in work, material well-being and freeing people from the bonds that tied them to restrictive moral codes, is centred on self-assertion and self-interest. The social repercussions of such a choice are considerable – growing individualism, the break-up of the traditional family, and the search for a new ethical code and morals consistent with the new socio-economic context. These changes are unnerving for many people because the traditionally reassuring landmarks have disappeared.

## Individualism

On a strictly individual and personal level, by establishing a society with strong hedonistic tendencies, the new economic transformations stimulate a perfectly legitimate desire for personal fulfilment, which threatens to lead to individualism. Far from being subjected to external laws or standards, individuals constitute their own standard and purpose in life. The rise of individualistic values that emphasize the freedom and autonomy of all people is demolishing the barriers of rigid standards. The rise of individualism is clearly a threat to the traditional family, the very foundation of social order. The pressure of combined economic, demographic, scientific and cultural transformations is fragmenting its traditional framework and patterns. Emerging at the end of a long history of social, moral, religious and legal victories, the individual is at last savouring the pleasure of 'self-possession'. However, this autonomy comes at a price – solitude and the loss of the meaningful horizons that used to govern life. As everyone knows, when there are no bonds with other people, life loses all meaning. There is no life without connectedness as Durkheim demonstrated in his thesis on suicide.

## The family – break-up of the traditional patterns

The democratization of the family, the demand for autonomy and its corollary, the general freeing of morals, are leading to the redefining and restructuring of traditional family ties. The shadow cast by the patriarch is gradually receding, and more room is being left for each individual's choice and self-expression. The direct consequences are a high divorce rate, the prevalence of unmarried couples, late marriages, and the advent of the limping, reconstituted family. Issues concerning the family are becoming increasingly complex owing to scientific advances in areas such as intervention of science, medically assisted reproduction, and sperm donation. In all these instances, the biological bond no longer coincides with the affective bond. Owing to their obscuring of affiliation, genetic manipulations may lead to a large number of lawsuits. Further down the line, this break-up of traditional family patterns could have repercussions on the exercise of authority in the school, in business and in all centralized institutions, thereby sounding the death knell for rigid, established hierarchies.

## Morality and religion – the collapse of the foundations

In a society given over to frivolous expenditure and waste, in which the pursuit of pleasure has become a priority, moral convictions can weaken and, under the pressure of scientific progress, belief in the supernatural, in another world with which we can communicate, is shaken. Faith begins to waver. Church attendance falls off against a background of growing religious indifference, offset, however, by the proliferation of sects in which freedom of expression, fervour and exuberant rites help to drive out the anxiety generated by the questions that science has left unanswered. It is against this backdrop of the collapse of Christianity and the metaphysics derived from it that the New Age

Movement, which is trying to reconcile science and faith, the subjective and the rational, has appeared. The results do not seem convincing.

Where morals and law are concerned, the genetic revolution that is opening up so many new avenues for medicine and justice (e.g. DNA fingerprinting) is disturbing since it makes possible the deliberate manipulation of life. Moreover, it calls for the drawing up of a new code of ethics and new laws. And where might the unfettered freedom of the Internet be leading us? How can children and young people be protected from the shocking or illegal things that it makes available? From the global, strategic point of view, the fact that the main non-renewable sources of energy (oil, gas) needed by the industries of the major powers are in the countries of the Third World is giving rise to merciless competition for their control and causing a growing number of local wars, thereby increasing the risk of worldwide conflict.

What the poor countries need is encouragement for endogenous policies, which, by stimulating local industries, would prevent globalization from covertly expanding cultural and technological heritage of the countries of the North. Moreover, such aid would spare the poor countries the present alarming brain drain – a phenomenon that paradoxically reverses the direction and the process of aid since, culturally and scientifically speaking at least, this type of aid goes from the poor countries to the rich!

## CONCLUSION

We are living through a time of crisis, a distinguishing feature of which is the eruption of new values that are bringing about far-reaching social change. There are changes in basic matters such as dress (jeans phenomenon), diet (the spread of McDonald's), the family, relations between the sexes, life in society, and childrearing. The advantages of modernity are undeniable. It is quite clear that scientific progress has improved our living conditions. However, valued means of deriving pleasure, scientific inventions and technological innovations also bring with them serious questions and concerns since it is still impossible to discern clearly what the future holds for humanity. And will it ever be possible?

In any event, suffering on a tremendous scale and injustice subsist. Injustice is even more serious in that it can now call on powerful technical resources. Boosted by scientific progress, the inordinate ambitions of people not always aware of the risks involved are frightening. Should we give up then? We know, however, that we cannot halt progress. It therefore remains for us to try to humanize progress, endowing it with ever more meaning that gives people grounds for hope in a beneficial alliance of knowledge, science and justice. In this way, progress and development would not only be a process of accumulating material goods, but also a process of adding a spiritual dimension to human action.

This would give meaning to the idea of progress and justify it. Without such an ethical aim, progress would indeed be meaningless and would pave the way to injustice, unemployment, war, stress, and poverty and, given the risks of self-destruction inherent in the uncontrolled use of technology, enduring anxiety.

# THE DISCIPLINES OF THE SCIENCES OF SOCIETY

*Peter Wagner* and *Björn Wittrock*, coordinators

## INTRODUCTION

*Peter Wagner* and *Björn Wittrock*

### THE EMERGENCE OF TWENTIETH-CENTURY DISCIPLINES

The dawn of the twentieth century witnessed a major restructuring in the social sciences – or rather, what is now known as the social sciences, since at the time, the term did not yet refer to the disciplines dealt with in this chapter. In some cases, fundamental transformations of approaches gave rise to the contemporary state of the disciplines. The *marginalized revolution* set the theoretical agenda for much of twentieth-century economics as the structural approach did for linguistics. In anthropology, the introduction of participant observation gave the field its methodological distinctness – comparable to stratigraphic excavation in archaeology, which was introduced in the nineteenth century. In sociology, the turn of the century, known as the 'classical' period, was characterized by a set of epistemological, methodological and political reflections which, taken together, constituted a discipline barely recognized by the period's academic institutions.

Such transformations, however, did not leave the other fields of inquiry untouched. Often, these transformations entailed a specialization or a more precise delineation of the area of expertise, which then demanded a new way of dividing up the entire intellectual space devoted to the study of social life.

Some of the older disciplines had been rather clearly and easily defined by their relation to social practices and institutions during the nineteenth century. Historical accounts of the development of national states commonly reflect a large dose of patriotism and nationalism. The field of law interpreted, systematized and justified national legal systems and trained their practitioners. The state sciences – now often considered the forerunner to current political science – aimed at a comprehensive approach to problems of governance and policymaking for the existing policies. In addition, geography and demography provided data on the state's territory and population.

While such practice-related tasks persisted, scholars in these fields felt the need to define their work more precisely in academic terms at the beginning of the twentieth century. Partly following the example of the natural sciences, which

greatly developed during the nineteenth century, partly responding to broader transformations of the university system, which re-emerged as the institutional locus of systematic research, social scientists devoted much energy to developing a scholarly definition and demarcation of their fields, be it through disciplinary treatises, such as for history and geography, or through the choice of theoretical foundations such as legal positivism in law or the theorem of the optimum population in demography. Significantly, despite the attempts made, state/political scientists did not achieve a recognized degree of disciplinary consolidation in similar form (except in the United States), and the area lost influence in relation to other disciplines, notably economics and history, but also sociology, until it re-emerged after the Second World War.

It is possible to state (with some significant reservations) that the set of disciplines of the social sciences, as we knew them at the end of the twentieth century, had barely emerged at the beginning of the century. However, at that time, it displayed a number of characteristics that should come under critical review in the course of the present century. First, the organization of the social sciences occurred as a 'local' model developed predominantly in Europe and North America. Second, it emerged as a set of academic disciplines, i.e. with an intrinsic idea of a cognitive order for the comprehensive study of the social world. Third, it was conceived as a set of 'sciences' in response to the period's prevailing crisis of science. In the present introduction, we shall briefly survey the development and transformation of these three features through the twentieth century.

### RELUCTANT GLOBALIZATION AND PLURALIZATION

Around 1900, considerable efforts were made to establish the sciences of society as international intellectual projects. An international institute for sociology was founded; historians started to convene international conferences; and in some areas such as economics or archaeology, the scholarly debate had become truly transnational. Furthermore, national European traditions in the social

sciences were spread across the globe through conscious attempts at adaptation (in Japan, for instance) through colonial domination as well as through migration and commercial encounters.

However, all of these developments must be understood against the background of profoundly national structures of scholarly work. During the nineteenth century, national intellectual traditions had consolidated like fortresses in Europe, created and sustained by national university systems and ideologies of nationalism. Denominations such as the French school of sociology for Durkheimian thinking, or the German school of economics for historical-institutional economic analysis were quite common. And the sincere attempts at internationalization were largely thwarted by the outbreak of the First World War.

During the interwar period, the late-nineteenth century situation of a plurality of competing national intellectual approaches, mostly confined to Europe and North America, was restored. The main difference was that the prestige of German academic institutions was gradually waning and that American social science started to emerge more strongly. These tendencies were strengthened by the advent of fascism, totalitarianism and war. Many German and Central European scholars, often of Jewish origin, fled, sometimes to France, the Soviet Union or Turkey, but more often they found a long-term, and often permanent home in the United States or in the United Kingdom. As a result, the European limited diversity of social science was replaced by what appeared, at least superficially, as a temporary American hegemony after the two world wars.

Following the Second World War, however, another immense shift in the global intellectual structure could be observed. From the 1960s onwards, the then-dominant social science approaches – often regarded as 'American', especially by non-Americans – were increasingly criticized, and intellectual traditions from so-called non-Western cultures asserted themselves more strongly in increasingly global multicultural encounters. In addition, some European traditions were also revived. The return of the anthropological perspective on Western societies, the final farewell to racist theories of the development of humankind in archaeology, the focus on linguistic pluralism, or the critique of legal positivism by postcolonial theories of law are examples of such developments.

## DISCIPLINES AND INTERDISCIPLINARITY

The formation of the disciplines that accompanied the revival of universities was generally a nineteenth-century process. At the beginning of the twentieth century, universities were increasingly organized according to disciplines, and both universities and disciplines had achieved some degree of institutional autonomy and intellectual consolidation. The disciplinary structure, however, was unevenly and inconsistently constituted, in the social and natural sciences alike.

It remained unclear whether social science disciplines were defined by subject, methodology and theoretical perspective or by reference to an area of practice or a profession. Anthropology, for example, differs from sociology by subject matter, i.e. the study of non-Western societies. This can be done, however, only at the cost of making the distinction between Western and non-Western

societies a fundamental one, which hardly anybody in either field today would wish to uphold. Perhaps the distinguishing quality of anthropology is its methodology involving extended participant observation. In that case, however, applying that method to political or economic phenomena in post-industrial societies would expand the sphere of anthropology at the expense of economics or political science. Similar illustrations could be given for all disciplines and all distinguishing criteria.

Today, in all fields of study interdisciplinary approaches are adopted from the outset. There are sociological approaches to law, economic approaches to demography, linguistic approaches to history, etc. By the end of the twentieth century, the strictly disciplinary structures were largely eroded; intellectuals focused primarily on questions that could often not be addressed by means of disciplinary theories. Furthermore, there were increasing expectations for social research to solve social problems and, accordingly, new institutional elements were introduced within university systems. As a result, much research examined socio-political problems, and often centred on state policy issues rather than disciplinary theory. In some fields, most notably in economics, this tendency led to marked distinctions between 'pure' and 'applied' social analysis, the former remaining disciplinary while the latter became either empirical or oriented towards ad hoc theorization with little concern for disciplines per se.

The current situation can probably be best described as hybrid: disciplinary traditions remain important at the universities for purposes of teaching and training, while there has been a shift of intellectual activity to areas where disciplinary approaches intermingle and are sometimes eliminated.

## SOCIAL ANALYSIS AS A SCIENCE

At the beginning of the twentieth century when many disciplines were taking shape, the issue of social analysis as a science was much debated. The era was characterized by a reorientation – sometimes leading to open crisis – in the natural sciences, away from a realist-representational vision of science towards a relativist-pragmatic perspective. Those involved in the emerging social sciences raised the question of whether they should, and still could, follow the nineteenth-century natural-science model or whether the new characteristics of society called for a different but equally scholarly approach.

Thoughts on those issues can be found in virtually all debates concerning the constitution of discipline around the turn of the twentieth century. The 'dispute over method', which started in the 1880s, to give one prominent example, dealt directly with history, economics and sociology and included epistemological and ontological as much as methodological issues. Despite the fact that the debate originated in Germany and Austria, it was widely followed and taken up in other countries.

For social analysis to be recognized as a science at that time, it was important either to agree on some necessary philosophical foundations for those projects or to strongly limit, or eschew entirely, such concerns by focusing on methodology. It was evident that the social sciences shared some characteristics with philosophies of history and anthropologies of human social life. The question was whether they could be formalized to such an extent that

they created theoretical research programmes (which occurred in the field of neoclassical economics) or whether they could be discarded in favour of empirical research strategies. To some extent, the latter took place, for example, in the field of history with the focus on archival research, in anthropology with the invention of participant observation, and in archaeology with the invention of radiocarbon dating.

For most of the other social sciences, quantification of social data appeared to provide the best solution for this problematic. Quantifiable data, in a nearly ready-to-use form, could be found in state-provided statistics or could be generated through surveys. Much methodological effort was devoted to the development of increasingly sophisticated techniques for treating those data. Beginning in the interwar period, quantitative social science reached its heyday during the 1960s, by which time it was extended to virtually all disciplines and sometimes equated, critically, with the American approach to social science.

By the end of the century, however, all of the once-pressing questions that appeared to have been answered returned to the fore. On the one hand, the implicit anthropology of 'modern' social sciences was questioned from a humanist perspective with a view to underlining differences between the natural and the social world and advocating a renewal of interpretive approaches. On the other hand, the philosophy of the dominant social sciences (and of the natural sciences as well) was criticized for pretending to work from secure foundations that can not be validated. The outcome of this situation is not a denial of the validity of social science (or of science in general) – though some current observers are worried about any such implications – but rather a renewal of the mixture of scepticism and pluralism that marked the end of the

nineteenth century. If nothing else, these most recent developments demonstrate the liveliness and creativity of the intellectual debates in the realm of social sciences, and there is every reason to believe that they will continue.

## AN EVOLVING GLOBAL INTELLECTUAL STRUCTURE

### History writing

Few people would deny that the discipline of history is less international in its internal structure than physics or even sociology. It is bound to languages, cultures and the past itself. In some respects it is more akin to legal studies than to natural science.

This does not imply, however, that history is necessarily less 'objective' than other scholarly activities. The fact that we have to know the language and the customs of the actors of the past to understand their thoughts and acts does not imply that the historian has to view their activities subjectively. And yet many historians have confused historical perspective with self-assertion, group identity formation and limited outlook, and in doing so, they have fuelled animosity and anger.

From its very beginnings, the discipline of history has been a mixture of politics and scholarship and this is still the case in the twentieth century. Many historians have accepted that history cannot be impartial, but they have struggled to find rules to minimize the influences of subjectivity and partiality. Consequently, the 'objectivity question' has been a central theme in the philosophy of history and the study of historiography.

Within the academic community of social sciences and humanities in the twentieth century, history is no longer on the forefront. Influences from other disciplines, including many new academic disciplines, have infused history with new facets. The blending of economics, political science, sociology and anthropology has given birth to hybrids that have fertilized history.

The discipline of history has thus become less focused on politics. Its current forms have given rise to new perspectives on interpreting society and its changes. Such new approaches are not accepted by all, and in addition to their cultural and linguistic particularities, historians differ with respect to their fundamental theory of history, which pre-dates the twentieth century.

### National perspectives before and after the First World War

The legacy of the nineteenth century persisted beyond the First World War. In Europe, this heritage was reflected in different ways. To begin with, history was one of the first disciplines in which professional researchers developed a clear code among themselves. Hofstadter writes: 'Up to about 1890, when Henry Adams was finishing his history, the major historians of the United States were still working in the tradition of the great amateurs. They were not formally trained to write history'.[1] In this respect, the professionnalization of historians was at least one generation ahead in many European countries. In France, early standards were set for the study of documents. In the nineteenth century Ranke, Waitz and Droysen had formed a German standard for the training of scholars within the discipline. A 'historical method' was developed, and historians could agree on historical 'facts' established according to these methodological rules. In Japan and China, long traditions existed in the scholarly writing of history. Yet, around the turn of the century, scholars in these countries consciously and explicitly merged domestic traditions with the most advanced European standards. Academic communities in many countries around the world followed suit. History as an academic discipline has been firmly professionalized since around the turn of the nineteenth century. History has, however, continued to be regarded as a subject of cultural entertainment that can be taken up by any interested person. Thus two partly overlapping traditions of history writing have developed.

Another legacy of the nineteenth century is the thematic content of history. History was regarded as primarily dealing with the state and its conflicts. Consequently, nationalism or a milder variety of patriotism was a main ingredient in the principal interpretations of history. Political history might vary, but the theme was traditional in most parts of the world.

Sato underlined another change in scholarly history of China and Japan. Historians were no longer the official spokespeople regarding imperial service. The European Enlightenment sparked a change of perspective that

continued to win ground in the new century; the learned were considered scholars with responsibility to the profession and the public only.

The European historical heritage of the nineteenth century was strongly national. It was most common to limit academic interest to the political history of one state only, and very often this national limitation led to a nationalist interpretation of relations with other countries. Late-nineteenth century radicalism and naturalism had counterparts in the writing of history, but these were undercurrents. The main paradigm was strictly national, only slightly more so in Germany (Sybel, Treitschke) and France (Lavisse) than in Britain or the smaller states of northern and central Europe.

The heirs to this ideological and scholarly stance reacted differently. Some developed the national theme further and approached totalitarianism or became fascists. Others took up the challenge of formulating an alternative and of viewing other aspects of history. From the interwar years, a national interpretation was no longer the only commonly accepted academic conception of the history of any European country. Social, economic and cultural factors competed with national ideas for prominence in explanations of historians.

Historians helped politicians define a national heritage. Nelson's Column in Trafalgar Square, the Siegessäule in Berlin and numerous other monuments glorified historic national achievements. After the First World War, all belligerent countries honoured their soldiers and commemorated their national past. It was most common among historians in Europe to write about these recent events or to glorify earlier national wars, as illustrated by the revival of the myth of King Karl XII in Sweden.[2] In the beginning of the century and in the interwar years, national history in Europe was dominated by an aggressive form of competition between countries, closely related to the fascism that developed in the same period. Although this is an important aspect of European historical writing, it is necessary to stress the elaboration of the national and political theme that also occurred at this time. Friedrich Meinecke, with his significant evaluations of German politics, the national state and state politics and power in history, was noteworthy but hardly alone.

The stress on the nationalistic aspects of history could also appear in other ways. In Germany, the opposition against the Versailles Peace Treaty stimulated local research combining history and anthropology in order to show the cultural heritage of the borderline provinces. This *völkische* research became a breeding ground for Nazi ideology.

Historians in the United States in the early twentieth century were bearers of a different cultural heritage than that of their European counterparts. The most renowned of the new historians reacted against the conservative state-centred approach of the previous generation. These so-called 'progressive' historians were led by Frederick Jackson Turner and Charles A. Beard. Turner, with his 'frontier thesis', which attempted to explain the American mind, and Beard, with his economic interpretation of the constitution combined with an isolationist stand, and other historians of their generation viewed history in the light of social science. They started out from assumptions of 'evidencing history' and contemporary tendencies of the social sciences in the interwar years and then supported these views. The paradigm was realistic. In this respect, American historians

were different from most Europeans, who tended to linger in epistemological idealism and were less inclined to regard history as a social science. The 'objectivity question' therefore had a different ring in the United States than in Europe.

National study of African history, in the European sense of the term, did not exist in the colonial period in the sub-Saharan regions. The colonizers attempted to record their own activities and accomplishments, but written history by domestic authors with a national perspective was lacking. To a certain extent, national traditions were transmitted with insufficient communication between colonizers and the colonized. Some recollections of slave experiences have been recorded, and other oral traditions have been saved, but these are limited primarily to the conditions of administrators and missionaries.

In the interwar years, most Latin American historians were trained in a positivistic tradition with the modernization of each country as the primary object of research. When Europeans and North Americans started to take an interest in the history of Latin America more extensively in the period after the Second World War, one major problem emerged: Why had Latin America developed so comparatively slowly in the period after the arrival of the Europeans? Underdevelopment and the theory of dependency, with André Gunder Franck as its most important advocate, underlay all explanations of the region's economic fate for a long period. However, not all history of Latin American countries has been tied to the theory of underdevelopment. The influence of the French *Annales* group and its distinctive approaches to history has been great in many countries of Latin America, particularly in Brazil. Already in the 1930s, Lucien Febvre and Marc Bloch established a link between Brazil and France. After the Second World War, the *Annales* devoted special issues to Brazilian history, and Frédéric Mauro, a disciple of Fernand Braudel, became professor of history in Sao Paolo, while other French historians working in Brazil helped to establish close historical connections between Brazilian and French culture.

Regionalism and economic perspectives on the history of Latin America easily blended with the influences from the *Annales* group and related French researchers. The Europeans working on Latin American history developed a great anthropological interest in the indigenous peoples and their history.

In contrast to most countries under the control of European colonial powers until the end of the Second World War, India had developed a flourishing group of domestic historical scholars. During the colonial period, many historians, like Jadunath Sarkar and Govind S. Sardesai, researched periods preceding the establishment of British power in India. Other historians, including Dadabhai Naroji and Romesh Chandra Dutt, held the British directly responsible for India's poverty and its lack of development. Thus the idea of a national history of India was voiced even before independence.

According to Ying-Shi Yü, the concept of national history was introduced to Chinese historiography in the early years of the twentieth century. Until that time, China was considered to be 'All-under-Heaven', which, according to Yü, best illustrates the Sinocentric world order.[3] The history of China, which was thought to encompass all that was worth knowing in the world, was not conceived as a whole: it was divided into dynasties and centred on the emperor.

Through the activities of Chang Ping-lin and Liang Ch'i-ch'ao, China developed a historical school emphasizing *national essence*, a term borrowed from Japan. According to this concept, China had a spirit of its own, which could not be copied but which should be preserved. The national message acquired a moral tinge just as this group embarked upon the task of writing the nation's history. Western influence was transmitted by Japanese scholars who had already absorbed the national theme in their works.

From the beginning of the 1920s, the National Past movement appeared as a new intellectual force in China. In 1922, Ku Chieh-kang began a critical study of Chinese historical traditions and their evolution as recorded in the classical novels. He demonstrated how the legends grew and new episodes were invented to enhance the prestige of the past emperors. Fu Ssu-nien followed this critical line still further by introducing a new element: he suggested that sources had to be penetrated in order to lay bare data that then could be used by the historian to present a nation's past. He and the other members of the National Past group wanted to make history scientific and objective. Although they managed to discredit traditional conceptions, they failed to propose a viable alternative.

Even though the National Past group was based on a conception of a national Chinese culture, its writings were mainly anti-nationalistic. When China was attacked by Japan in 1937, nationalistic feelings surfaced more openly in Chinese society and even Fu contributed with his historical study. Others went further: for example, Ch'ien Mu wrote a narrative outline of Chinese history, which assured the reader of China's illustrious past and future possibilities. Both Marxists and 'dataists' resented it even though its nationalism was more cultural than militaristic.

Around the turn of the nineteenth century, Japanese historians often referred to European historiography. In the context of Japan's rising military power, the national heritage with the unbroken dynastic line of the imperial family was raised to a position of prominence. The nationalistic view of history known as Kokoku-shikan, depicting Japan as the country of Tenno (the imperial god-relation), was adopted by many historians in the first four decades of the twentieth century. Contrasting views persisted however as illustrated by the fact that Marxist historians were numerous and often voiced their views during the interwar years.

After the Second World War, Marxism maintained a strong following among Japanese historians, but it was adapted to the local context. Economic history, and more specifically business history, remains firmly implanted in Japan, and social history of the variety associated with the *Annales* has become widely recognized and practiced.

**World congresses**

The world congresses of history began with the twentieth century. Indeed, the first so-called world congress of history – officially an 'international congress' – took place in Paris in 1900. Among the non-European countries attending the congress were Algeria, Argentina, Australia, Brazil, Canada, Chile, Cuba, Dominican Republic, Iran, Libya, Mexico, South Africa, Turkey and Venezuela. Each country, except Cuba and Mexico, sent one participant. Considering that only 100 to 200 of the 864 pre-registered participants actually attended the congresses, it can be

assumed that some of the few historians from far-away countries did not attend.

Erdmann's thorough analysis of all the congresses up to the Second World War provides a very clear picture of the dominant position of the Europeans, and particularly the Germans and French followed by the English, Italians, Belgians, and Poles. The only other country to play a leading role at those early congresses was the United States.

The congresses in Paris, Rome, Berlin and London, which took place between 1900 and 1913, were more European in scope than international. When the congress meetings were resumed after the First World War in Brussels in 1923, only a handful of non-European countries registered: Canada, Egypt, Japan, Lebanon, Rhodesia, South Africa, Turkey and the United States. Approximately half of the registered participants actually attended the congress.

Hopes rose when a standing committee was formed in 1926. The Comité International des Sciences Historiques (CISH) was to bear the responsibility for organizing the congresses. An American, Waldo Leland, played a prominent role in the formation of the organization, but the CISH was barely more international than the preceding congresses. Argentina, Brazil, Chile and Japan were the only non-European countries beside the United States invited to participate in CISH from its inception. Beginning in the 1930s, Soviet representatives were incorporated in the international committee and the smaller European countries were better represented. Although the circle had been widened, it remained restricted to a small number of countries.

The first effort actively to involve the major Asian nations in the work of the CISH was made by the committee's president, Harold Temperley. Travelling to Japan, China and India in 1937, Temperley managed to arouse interest for an active membership in the CISH from these countries and requested the organization's Bureau to quickly initiate new forms of cooperation. At the following congress in 1938, Japan was not represented at all; China and India sent one and five representatives, respectively. As this congress was dominated by the political and ideological tensions within Europe, Temperley's initiative had little lasting effect.

In fact, CISH has never become a truly international body. When, for the first time in 1995, a serious proposal was made to hold the next congress outside the Europe-North America axis, a European location was ultimately selected. The Bureau elected in Montreal in 1995 consists of representatives from six European countries, the United States, Canada, India and Japan, and a Hungarian president who resides in the United States. China and South-East Asia, Africa and South America were not represented. Problems formulated in Europe or the United States are regarded as the main problems of historical scholarship, and generally relate to questions on a specific history or the theory of history. Some efforts have been made to integrate scholars from Asia, Latin America and Africa in the discussions of the congresses, especially from 1965 onwards. Individual scholars from these regions of the world have been able to put forward their interpretations of important themes. Often language has been an obstacle since the languages of oral presentations are traditionally English, French or one or two other European languages. Non-European languages

have never been accepted as the basis for communication in this international community.

## Post-Second World War developments

The national perspective on history has acquired new relevance in recent years. History is part of a new formation of national identities in Eastern Europe, Africa and extensive regions of Asia. The Second World War and its consequences, and to an even larger extent, the decolonization process have contributed to changes in the world's perception of history. National history has become not only strengthened but also transformed through this process.

The political situation in much of the world was transformed after the Second World War. In China, communist historians made efforts to combine Marx's views on Asiatic societies with Chinese history as early as the 1930s. Much attention was devoted to the question of the meaning of the 'Asiatic mode of production'. The weakness of capitalism in relation to the feudal system in China also became a point of discussion among historians. After the Chinese Revolution, many wondered whether the Revolution could be regarded as a socialist revolution in Marxist terms. Chinese historians in the period after 1949 favoured an approach combining an evaluation of the relatively progressive effects of events and social data with a 'class viewpoint' assessment of the Revolution. However, the Chinese showed a continuing interest in Western historiography and, except during the Cultural Revolution, the links with the development of the discipline in other countries was preserved.

In India, independence meant a new start in many areas, including the discipline of history. Ancient and medieval Indian history have made great advances, and D. D. Kosambi and Romila Thapar among others have shed new light on the agrarian structures resulting from relations between religion, caste and family in these periods. Economic and social history have developed rapidly and become very successful in independent India with analyses of social consequences of major economic enterprises emerging as a major sub-field of inquiry. Politically, however, the main interest has focused on the struggle for independence. Bipan Chandra and others have shown how the anti-imperialist struggle gave rise to a new national identity in a country deeply divided by ethnic, linguistic and religious problems.

As a nation, Nigeria was a colonial creation, but Britain was guided by ethnological, geographical and historical factors, contends Ade Ajayi. After liberation from the British, national Nigerian historians sought to evaluate the British rule. Marxist historians criticized the basis of national historiography and urged reviewing Nigerian history in the light of development. Ajayi asserts that the criticism did not change the opinions of nationalist historians, who unanimously rejected the theory of underdevelopment as being more applicable to Latin America and its long colonial history, than to Nigeria, where colonialism lasted no more than 100 years. Nationalist historiography stressed the continuity with the pre-colonial past.

In Zaire, European scholars and historians trained in Europe played an important role in the early stages. Only gradually were indigenous scholars trained to conduct studies from a national perspective. A restructuring of higher education in the country took place at the national University of Zaire in 1971, endowing Zairean history and historians with established positions. After 1970, national research mainly focused on themes related to the colonial period and earlier. Research carried out on Zaire's diverse communities transcends state borders. Particular emphasis has been placed on ethnographic history and the use of technology.

In the German Democratic Republic as in the Federal Republic of Germany, historians endeavoured to deal with their traumatic past. Although there were two German states, historians of both countries studied the same national history before 1945. Given its close relation to the Soviet Union, the GDR demanded a Marxist outlook from its scholars, and in many respects historians of the GDR were more doctrinaire than those in other countries of the so-called Eastern Bloc. It seems, however, that this historical orthodoxy diminished after 1970.

Many important contributions to German and European history were made by East German historians adopting the perspective of historical materialism. Beginning in the 1970s, both older and younger historians took a freer approach to material interpretation – the biographies of Bismarck and Frederick the Great by Ernst Engelberg and Ingrid Mittenzwei, respectively, may serve as examples – but they used it to maintain a safe distance from the heritage of German historicism and research in West Germany. The critics of East German history in the West were harsh, and after the fall of the Berlin Wall in 1989, they were joined by some historians from the former GDR.

In communist Hungary, historical materialism was not as rigid as in the GDR, and Hungarian historians were not as preoccupied as their German colleagues with their national past. These two circumstances proved important for the relatively flourishing state of Hungarian historical scholarship after 1945. Led by György Ranki and Ivan Berend, Hungarian historians have played an important role in reconceiving European and international history by combining economic and cultural data.

The history of the Russian Revolution has inspired many thorough studies of the actors and events in that period of turmoil. Of course, political scientists were extremely interested in the Soviet Union, but historians, both Russian and Western, have also made important contributions to the study of this overly centralized system. Yet, explaining a structure that is expected to last is different from explaining structural change. Since *perestroika* the main problem has been to determine the causes of political and social change, and a so-called *civilization approach* has been favoured by Russian historians, who combine class analysis and economic organization with cultural phenomena. Again, some explanations tend to focus on prominent actors, while others select theoretical models of economics.

## The opening up of national boundaries

Naturally, most historians choose to work on subjects related to their own nations. This also holds true for Jewish historians dealing with Jewish history, even though Max Beloff's observation on the difficulties of defining the object of Jewish history is pertinent. Researchers concentrating on national history normally know the language well and can rely on a great deal of tacit knowledge. In addition, national

researchers can access source material more easily than their foreign colleagues. One can therefore argue that it is logical that historians give priority to the history they regard as 'theirs'. However, the mainly post-Second World War phenomenon of researchers studying their national history has been seriously challenged in recent years.

One of the positive effects of the international congresses of history is the establishment of a large number of commissions and associations for specific fields of research. Many of these commissions function independently of the congresses by organizing their own meetings and conferences. Some commissions have existed for a long time. Europeans and North Americans still play a major role in these commissions, and in many cases their participation has increased, while the involvement of historians from other parts of the world remains low.

Today's scholars are much more mobile than ever before. However, this does not mean that the labour market of historians has become truly international, for most positions are reserved for those scholars culturally linked to the country despite the fact that recruitment is officially open to all. Although it is true that the academic labour market was more closed in the past, professional scholars of history are much more confined to a particular cultural milieu than their counterparts in all science disciplines and in many social sciences and the arts.

Despite such restrictions, a change has taken place. In Europe and North America, it is common to find academic historians who were not born in the country where they work. In order to obtain their positions, they must adapt to the rules of the institution. Most have settled permanently in the country and are quite familiar with its language. Some come from countries within the Euro-American circle. Those from the Third World are more likely to work in the Unites States than in Europe. Europeans and Americans working in Third World countries often have temporary assignments from research or relief foundations. Even if they endeavour to establish contacts with the researchers in the country where they work, they are less likely to succeed than those with tenured positions in universities or academies.

### International research and the question of perspective

Scholars from Europe and the United States have shown much interest in investigating the history of former colonies, sometimes spreading this interest to other countries. At present, important centres for primary research work on the history of world cultures have been created in the United States, Russia, France, Germany and Japan. Former colonial powers are particularly committed to studying the history of their former colonies, as attested by the important handbook series on several countries published by Oxford and Cambridge universities. This field of study, initiated during the colonial period, has been carried on and even extended to other countries.

Several historians from Europe worked on colonial history during the colonial period. They did not restrict their research to themes related to the period of European domination, and some continued to be extremely respected in academic circles. The most devoted have undertaken widely esteemed research and educational work after the dissolution of colonial power, notably the US-based Belgian specialist Jan Vansina, and several other Belgian, French (e.g. Catherine Coqery-Vidrovich), Portuguese, American and British researchers who have studied in the former Congo and Angola. In the former French colonies of West Africa, French researchers have done important work. Dutch historians have played a leading role in Indonesia, and many American and British researchers have contributed to the historical knowledge of India.

## THE DISCIPLINE OF HISTORY

### History – the continuation of a great tradition

The tradition of writing and studying history predates the development of higher education. Thus history, unlike many other disciplines, was not the fruit of opposition against other predominant approaches to knowledge but has rather engendered many disciplines. Over the last century, history like most other disciplines has undergone an enormous degree of specialization. Nevertheless, the field has proven remarkably cohesive as evidenced by the fact that most specialists prefer to be regarded as historians contributing to an overall historical discipline rather than belonging to an independent discipline.

### Specialization and anti-specialization in historical perspective

The first great wave of specialization within the discipline of history occurred at the turn of the twentieth century when bitter fights erupted over economic history and cultural history. It should be noted that when the world congresses of history were first created in 1898, they focused on diplomatic history. The scope was widened in 1900 in keeping with the belief that the 'historical method' rather than a topic should decide the breadth of history, as expressed by Boissier, the president of the 1900 congress.

A new wave of specialization appeared after the Second World War. Scholars showed a great interest in themes whose temporary nature ensured cohesion within the field. Many themes died out, while others managed to survive, albeit less vigourously. *Economic history* underwent great diversification in the twentieth century. In 1960, an independent international organization devoted specifically to economic history was established. Economic history greatly overlaps with social history. One sub-branch of this field is the history of national economies, which is closely connected with economic theory. Its relevance is determined by theoretical perspective. Such studies take up questions regarding the history of industry and business and the conditions required for their change, including the role of technology. Most of these studies concern the situation in the United States, though they have sometimes been applied to other parts of the world.

Industrial organization and the role of management have been studied by a group of scholars, inspired primarily by the American Alfred D. Chandler. Europeans from different countries have joined this field of research and contributed new perspectives. This sub-branch of economic history is closely related to the history of individual firms, which is in great demand among industrial and business concerns. Other fields of research in economic history include nutrition and food in history, agrarian development, the

economic conditions of caravan trade and high-sea transport. Thus, economic history has developed in different directions establishing itself as a discipline in its own right in many countries and becoming almost as multi-faceted as history itself.

Very rapidly, social history also became multi-faceted and almost all-embracing. At an early stage, it acquired political as well as sociological orientations. History of social policy received much attention in the early twentieth century, when different social policy measures were first compared systematically. This starting point led to thorough investigations of the welfare state and, in recent decades, to an analysis of the discipline of the well-ordered absolutist state and the social policy of earlier centuries. Crime, violence and the judicial process have also come to the foreground.

Historical materialism, as described by Marx and Engels, has provided valuable insights to many Western and Eastern historians of this century towards the understanding of history. This field has long dominated economic and social history in many countries. Although several schools of historical materialism have emerged, there is a dividing line between structural, and cultural and intellectual interpretations. Georg Lukacs and E. P. Thompson are the main proponents of the latter approach, while the structural interpretation has been advocated by theoreticians such as Althusser and his followers.

Class analysis, often derived from historical materialism, has been a vital branch of social history throughout the twentieth century. This was officially adopted by the Soviet Union in the wake of the Russian Revolution. After the domination of a dogmatic leftist interpretation under the leadership of Pokrovsky during the late 1920s, history was forced to submit to the will of Stalin in the early 1930s. Although Stalin's terror was devastating for many scholarly works on Russian history and other disciplines, it did not seem to affect historical studies of the West, which were not forced to include Stalin's own views. This enabled some researchers to work rather freely from the basis of historical materialism. After the Second World War, a formal Marxist perspective became compulsory in the communist countries of Eastern Europe, China and North Korea. As a result, class analysis of society came to the fore as a main current of historical research.

In the West, several leftist historians had devoted many years of research on social history, and the Marxist revival of the late 1960s and 1970s increased the contributions in the field. Eric J. Hobsbawm, who undertook several substantial investigations of working-class movements in relation to social conditions and other wide-ranging studies, and E. P. Thompson, author of *Making of the English Working Class* (1963), represent different currents within the British tradition. The French Revolution, popular as a historic example among Russian Marxists, especially Trotskyites, provided inspiration for Marxist-orientated social historical analysis by Albert Mathiez, Albert Soboul and Georges Lefebvre. In Poland, Witold Kula's new analyses of the European agrarian economy in the sixteenth and seventeenth centuries prompted Western European historians to renew their investigations on this subject. Eugene Genovese and Elizabeth Fox Genovese, working in the United States, fought econometricians for a more Marxist-inspired perspective in their analysis of slavery.

Social mobility and migration have been widely investigated in the context of Europe and the United States, while the history of Chinese emigration, so pervasive in Asia and America, has been far less studied. The related topics of geographical and social mobility have often been treated together in the context of geographical and sociological theory. Political scientists have advanced the study of institutions and bureaucracy and the relationship between state and society. Thus the boundary between social and political history is once again blurred.

At the beginning of the twentieth century, a fierce discussion sparked by Karl Lamprecht's work on German history and his ideas on political history arose in Germany over the status of *cultural history*. In his writings, Lamprecht relegated political history to a secondary role, in favour of economic history and the history of law, ideas and arts, all of which he considered more fundamental. Lamprecht's ideas spread mainly in France and in parts of northern Europe.

The status and scope of cultural history was ambiguous. Its advocates wanted, on the one hand, to encompass all of history and, on the other hand, to emphasize those aspects of human life, such as customs, ideas, and art, that had been only marginally treated elsewhere. Such themes soon developed into specialities of their own. Intellectual history, as the history of thoughts and ideas, had long been explored by historians, but its more specific sub-categories involving links to ancient philosophy or to modern science flourished during the interwar years.

The relationship between scientific concepts and popular ideas became a main theme in history after the Second World War and prompted an interest in pseudo-science, as exemplified by Carlo Ginzburg's *The Cheese and the Worms*, or Emmanuel Le Roy Ladurie's paradigmatic *Montaillou*. Natalie Zemon Davies brought the genre into the field of life-values and identities with the story of Martin Guerre, and Robert Darnton, Jacques Le Goff and Aaron J. Gurevich have analysed other aspects of popular conceptualizations and their backgrounds. Peter Burke has made similar contributions in the realm of political culture. All these authors have worked within the genre commonly referred to as the 'history of mentalities'.

Another principal type of specialization deals with a specific period in the history of a country. Historians who concentrated on one king or one revolutionary sequence of events were following a paradigm that figured prominently in the first half of the century. Although this paradigm was called into question after the Second World War, it has neither disappeared nor been superseded. Few of these specialities were as successful as the study of the French Revolution, which led to the foundation of a specialized historical society with its own regularly published journal, *Annales historiques de la Révolution française*. Most other specialized periods of study only created informal networks of researchers, who were familiar with each other's works and sometimes met, but who were also competing for material and theories.

The theories of Marx and Weber can apply to all aspects of human life. Alternative comprehensive theories have been expounded, but they often only partially cover the wide gamut of human activity. Although economic theories have a different scope, they have most strongly impacted economic history in a restricted manner.

*Demography* contrasts with the other fields because it has been expanding in different directions and has attracted

many historians. What started out as a history of populations, migration and families, in general terms, has developed among other things into a specific family history. Such research was pioneered by Peter Laslett of Cambridge University, while more anthropological studies of past marriage patterns were inspired by the work of the Hungarian researcher J. Hajnal.

*Women's history* developed as an offshoot of family history, a field that attracted many women. Louise Tilly and Joan Scott, both from the United States, wrote a well-known overview of women in history. Feminists of the early 1980s proposed transforming the term *history* to 'herstory' and to ensure more visibility for women in history, thus leading to the creation of a new ideological system.

Another area of research that grew out of women's studies in the late 1980s was *gender theory*. An important branch of history in recent years, *gender history* encompasses a variety of approaches, which are all based on the shared assumption that along with biological sex, there exists a social construct of gender that provides a rule system for men and women in society. As a social rule system, it is subject to change, and comparisons of gender history have proved fruitful. One of the most influential specialists of gender history links it with postmodern linguistic relativism,[4] but this is not a generally accepted assumption among gender historians. In terms of the number of historians recruited, the field of gender history seems to be the fastest-growing branch of history over the last few years.

## Research centres and interdisciplinarity

While the nineteenth century saw the birth of the historical seminar characterized by the conscientious weighing of interpretation of sources and of their validity, the twentieth century witnessed the creation of advanced institutes of research with very broad or limited thematic scopes of interest. Institutional stability has increased. In most countries, actual departments of history were rare at the beginning of the last century. The institutional growth that occurred over the course of the twentieth century has created a congenial environment for scholars to test ideas informally and has ensured a future for new generations of historians. The principal drawback of institutional structures is a certain streamlining of academic research. In addition, the role of individualism in historical scholarship has been considerably diminished over the last century.

Several major research institutes have been particularly influential, especially in the period after the Second World War. Founded in 1963, La Maison des sciences de l'homme in Paris is an unusually broad research centre, and in this respect, it is unique among French institutes. The institution embraces almost all fields of social sciences, but is particularly renowned in the fields of sociology and history. Since its creation, it has hosted the *Annales* group, which is well suited to the Maison's interdisciplinary environment, given its commitment to break down the limits of history and uncover new fields for historical research.

Despite differences in structure and objectives, the Institute for Advanced Study in Princeton can be compared to the prestigious Parisian research institute. As has been the case in some other institutes of advanced study – the Wissenschaftskolleg in Berlin, The Netherlands Institute of Advanced Study in Wassenaar, the National Humanities

Center in North Carolina (USA), and the Swedish Collegium for Advanced Study in the Social Sciences – historians have been invited to the Institute for Advanced Study for a limited period to pursue their research. The same holds true for the Indian Institute of Advanced Study in Shimla.

In these special environments, historians participate in research discussions and joint projects with scholars of the social sciences and arts. Another approach is taken by the ZIF (Center for Interdisciplinary Research) in Bielefeld, Germany, where guest historians participate in thematically organized research groups.

At the institutes of the Russian Academy of Sciences (notably the institutes for Russian and world history in Moscow), historians collaborate with researchers from other disciplines, especially anthropology and archaeology. Other former communist countries have founded similar institutes, which are often specifically devoted to history but maintain professional contacts with other disciplines.

The growth of the interdisciplinary research institutes has taken place largely since the Second World War, though preliminary steps were taken in the interwar years. Through these institutes and many more loosely organized university networks, historians have become part of a growing worldwide interdisciplinary culture. In this regard, the interrelation of findings from different disciplines has become an urgent problem.

## History as a basis for the formation of national identities

In the early decades of the twentieth century, national histories with a nationalist slant incited lively debate. New fuel for the emotional fire was provided by the events of the First World War, but a new scepticism in regard to nationalism in scholarly works also emerged. Many highly praised works on national history of the late nineteenth century could not have been written after 1918. Another type of history, written by prominent scholars in the service of state ideologies, eventually appeared. It is well known that National Socialism in Germany placed demands on scholars to produce such works, but Germany was not the only example. This genre has survived to the present day, taking the form, beginning in the 1990s, of ideologically biased history, which uses a theory of history (postmodernism or relativism) to proclaim utopian interpretations of history for the sake of an ideology.

Historical scholars, when not pressured to take up the state's cause, have become more and more cautious in the use of nationally loaded symbolism. Many have used their talents to unveil the dangers and the emptiness of national symbols. German debate over the Holocaust (*Historikerstreit*), which broke out in 1986, demonstrates that not all scholars are pursuing the same goals. Some wanted to restore a national interpretation of history for the sake of inspiring the people with national pride, while others hoped 'enlightenment' would replace such national pride. 'Making sense of history' (*Sinnstiftung*) and 'recreation of identity' (*Identitätsstiftung*) meant for the former group of scholars to give Germans a sense of pride in a heritage from the past in spite of 'Kaiserism' and Nazism. For their opponents, the identity-formation associated with these terms was a dangerous exercise motivated by political

considerations rather than by scholarship. A great corpus of literature on this debate was published at the end of the 1980s.

To accept a historical past of sharp contradictions in values and ideals or to discriminate between them and take a clear position is a choice which has become more and more urgent for historians of all nationalities. Few countries enjoyed a pacific existence in the twentieth century. For most peoples, the past hundred years have been marked by tremendous violence and turmoil, and their own nation has not always sided with the forces of good, the harassed and the victims. A special case is Holocaust research and the European history of the Jews. Often atrocities constitute a part of the past of one's country. To avoid both the Scylla of racism and the Charybdis of nationalism and to give proper weight to biological heritage and identification are tests that have to be passed by historians in many countries. Establishing national identity through history is not an easy achievement.

### A theory of history as a philosophical identity-formation

Like historians of past centuries, few twentieth-century historians have actively participated in the ongoing debate on the philosophy of history. Some earlier historians did write on philosophical problems of history, but they were exceptional cases. In the Soviet Union, the theory of history played an important role, and differences in the interpretation of historical materialism were growing in the 1960s and 1980s. In recent decades, discussions on these topics were reported in the only specialized journal in the field, *History and Theory* (inaugurated in 1960). It is striking that most of the contributors are philosophers or professional historical theorists.

However, in recent world congresses and in the general debate, the theory of history attracts great interest from general historians. Perhaps most historians have opinions on the theory of history, the past per se and the nature of historical understanding. It seems that the 'linguistic turn' of historical theory and 'postmodernism' have contributed to the widespread appeal.

However, this does not necessarily mean that historians have become more unified in their theoretical outlook. In spite of differences of viewpoints and fundamental beliefs, the theory of history seems to serve increasingly as a means of identification for historians of different specialties. The narrower specialities become, the greater the need for a more general basis of identity, even though this does not lead to a more unified community of historians.

### History of historiography

In contrast to the theory of history, the history of historiography has generated widespread interest among historians. Many have written at least one contribution on the subject, but the degree of specialization is limited. Few of those working on problems of the history of historiography devote themselves exclusively or mainly to such themes. Historians inevitably feel that they are either part of a research tradition or revolting against one. The history of historiography in this way serves to provide a common

heritage for historians. This heritage has grown increasingly international, as the historiography of the East has become known in the West and as the ideals of research professionalism have spread from Europe to the rest of the world.

### Growing unity and increasing diversity

In the face of adverse odds, history as an academic discipline and field of research has become increasingly similar over the world. Strong forces have worked against the formation of a single academic community. History can be created only through an intimate knowledge of the cultural and linguistic rules which have determined the material and constitute its foundations. Furthermore, history like many other academic disciplines has become increasingly specialized in the twentieth century. Both of the above conditions could theoretically prevent or diminish understanding between historians.

The counterforces have also been strong. An international assembly of historians has been successfully orchestrating world congresses, which have gradually become more international. Earlier specialization in national histories found competition from thematic specialities during the twentieth century, which means that there now exists a profusion of networks among historians from different countries with a common interest in a particular field of historical study. Moreover, historians of the twentieth century have become more used to seeking assistance from other disciplines in the form of social theories or methods of research. Interdisciplinary work by means of borderline research or organized teamwork has further linked historians to a wider academic community. 'Universal' history, attempting to embrace development in all its facets, has had rather few advocates and practitioners. The ambition to write an all-embracing history (*histoire globale*) has led to the rise of new aspects and the continuous inclusion of new fields into the realm of history, rather than to new overall perspectives.

The theory of history and the history of historiography are now specialities in their own right. For the general historian, however, they have another and more significant importance: they are tools for the self-understanding of historians as members of a scholarly community. The more historians from different countries meet, the more they need something beyond a speciality to clarify their identity as historians in order to prevent the community from splintering into a number of specialities. In the last half-century, historians have recognized this need, and they have been lucky to have the two possibilities mentioned to canalize their growing uncertainty of history as a whole and of the 'historical community'. For this reason, these scholars can still consider themselves historians in spite of the ongoing specialization.

Most striking is the rapid internationalization of these developments. What was only a partial and slowly developing community among historical researchers in the first half of the twentieth century has rapidly grown in scope and intensity. Fundamental methodologies and rule systems are acknowledged all over the academic world of historians, and although failures to live up to the rules do occur, they are not limited to certain countries. Paradoxically, postmodernist relativism facilitated the acceptance of

common standards, at a time when the ideal of attaining an objective and common true history has been abandoned (if it ever existed). The global academic community of historians, which was not desired by many historians only a couple of generations ago, is now well on its way.

## ANTHROPOLOGY AND ETHNOLOGY

### *Heidrun Friese*

Bronislaw Malinowski sailed towards the objects of his future study, escaping the European battlegrounds in the expectation of being received by the administrators of colonial power in New Guinea (Plate 96). His mind was filled with Conrad's novels and morphine and 'impure thoughts' and his luggage contained the research guidelines of the 'Notes and Queries'. His view of the 'exotic' world he would soon encounter was interwoven with mythological and culture-critical images of a closed unitary community and resembled an estranged self-image of his own 'Western society'. Nevertheless, the brave Malinowski was one of the first 'heroes' of a new anthropology[1] who said farewell to the universalistic and evolutionist classification systems of the 'armchair anthropologists' of the nineteenth century (e.g. James Frazer and Edward Burnett Tylor) and – together with Reginald Radcliffe-Brown, Margaret Mead and Marcel Griaule – established *participant observation* in field research as a professional research methodology. Up to the present day, extended field research is seen as a requirement of anthropological analysis; it thus provided a common, scientifically acknowledged method and convention for what otherwise remained a diverse variety of anthropological perspectives. It was participant observation that allowed the discipline to distinguish itself in terms of methodology from Western sociology, itself an emerging discipline of that period.

In terms of substantive orientation, anthropological discourse developed specific ways of setting boundaries of exclusion and identity in the making of its objects by means of segregating the 'other' from a 'we' that had to be constructed as well. The fact that anthropology and sociology developed as separate disciplines for the study of contemporary societies presupposed a strong distinction between 'us' and the 'others'. The mode of constructing the other therefore constitutes a persistent implicit problematic of anthropology. It has become central and explicit in more recent debates, when anthropology has focused on the societies from which it originated and has played a key role in epistemological debates common to all the human and social sciences. These recent developments have also entailed a kind of dissolution of the boundary between anthropology and sociology, which was never very stable and clear-cut in theoretical terms. In this chapter, we will thus refer to a number of authors who are similarly claimed by the sociological tradition (see sub-chapter 19.6 on sociology). The criticism directed against the definition of the object of anthropological research that relied on the Eurocentric construction of a 'modern' self versus a 'primitive-traditional' other has also led to the establishment of fields of study labelled 'sociology/comparative sociology' in societies which used to be regarded as 'other' from a Western viewpoint.[2]

In 1871, E. B. Tylor defined culture as 'that complex whole which includes knowledge, belief, arts, morals, custom, and other capabilities and habits acquired by man as a member of society'. Thus, the perspectives of British social anthropology, which placed special emphasis on 'society', and of American cultural anthropology, which underlined the historical-cultural aspects of human social life, appear complementary rather than contradictory.[3] Differentiation and pluralization of the discipline, on the one hand, and transnational diffusion of theoretical concepts and research areas, on the other hand, as well as the opening towards other disciplines (sociology, history, psychology, literary theory, theory and history of art) have further diminished the importance of these conceptual boundaries during the twentieth century. The persistence of terminological differences is nowadays due to the inertia of academic structures (which tend to eternalize traditional terminologies) rather than to clear-cut theoretical boundaries.

Instead of reiterating traditional distinctions, we shall try to identify the points of convergence of the various approaches, their founding presuppositions, matrices of concepts and key topics, and we shall try to demonstrate how they attempted to answer some of the key questions of cultural and social thought such as the relation between the individual and the social space, and the temporality of human social life and its representation.

### INTEGRATION, NORM AND FUNCTION

The methodology of field research standardized since Malinowski, which no longer relies on reports by travellers, missionaries or colonial officers but on the anthropologist's own experience of social life, was not merely to guarantee

the authoritative status of the qualified scholar and her or his initiation into the academic corporation and its reputation. The thus-instituted dialectics of researching subject and researched object, of privileged 'view from inside' and 'distance' to the object, which regarded the direct and contemporaneous experience of the 'other' as a precondition for valid analysis and interpretation, was also meant to provide an objective and theoretically integrated overall picture of the examined society and allow for generalizations, i.e. the identification of regularities in social life, of its institutions, values and norms, rules and laws.

However, the new genre of ethnography, with its naturalistic-realistic mode of writing, was not only characterized by its emphasis on the authority of its own observations in the textual representation of the 'other'. Being synchronically locked into the ethnographic present, the observed societies were constructed as static and ahistoric ensembles of characteristic forms of behaviour and collective representations, which formed a coherent and homogenous whole (Emile Durkheim, Marcel Mauss, Lucien Lévy-Bruhl). Key research subjects in the traditions of both social and cultural anthropology accordingly involved the *functional integration* of a society governed by the analytical subdivision of the societal whole into harmoniously related sociocultural realms – such as social organization, economy, religion and law. The North American 'culture and personality' studies, which relied on the common assumption of 'functional interdependencies and value orientations that bring structure to a culture and regulate its systemic processes'[4] regarded the cultural integration of the individuals as being mediated by 'basic emotional stylization', 'cultural patterns' or 'psychology types' (Margaret Mead, Ruth Benedict), by 'dominant culture interests' (Ralph Linton) or 'values and world view' (Clyde Kluckhohn, Robert Redfield). The European perspective, in contrast, saw stability being achieved by the integration of partial societal realms and institutions (Emile Durkheim) and accordingly emphasized the study of social relations and social structures (Reginald Radcliffe-Brown, Edward Evans-Pritchard). In both cases, however, the dominant theoretical paradigms were oriented towards the categories of *integration, norm and function* despite all differences between the concepts and intellectual genealogies of the schools.

This common theoretical programme was based on two basic underlying assumptions. First, the reality of society was conceived as lying somehow behind, under, or outside of the notions and 'self-explanations' given by a group or society. Its essence could therefore only be grasped by means of theoretical construction (Karl Marx, Emile Durkheim, Talcott Parsons). Second, society could be seen as a somehow stable and harmonious whole, which gained an internal dynamic and social change predominantly through exogenous factors, such as colonial subjugation. Although, in exceptional cases, as Max Gluckman already pointed out, societies do not remain in a harmonious state of equilibrium, but establish themselves through conflict and contradiction. The procedure of analysis and cross-cultural comparison, therefore, was the construction of segregated, homogeneous and well-integrated entities. It was based on the presuppositions of an epistemological break between 'subject' and 'object' and of congruence between historical distance and cultural difference.

## DIVISION, OPPOSITION AND MEDIATION

These assumptions and analytical procedures of the structural-functional school and its mighty discourses – which also predominated in the academic institutions of the countries subjugated by colonialism such as the Rhodes-Livingston Institute (northern Rhodesia), the East African Institute of Social Research (Uganda) and the West African Institute of Social and Economic Research (Nigeria[5]) – found their continuations in the episteme of French structuralism, which linked the Saussurean linguistic heritage to anthropology (see Claude Lévi-Strauss' four-volume textual interpretation of the myths of both Americas, *Mythologiques*). The variety of social and cultural phenomena 'could be rendered intelligible by demonstrating the shared relationships of those phenomena to a few simple underlying principles' and by recourse to the universally valid binary oppositions of the human mind. Cultures were predominantly understood as systems of classification, and 'one of the most secondary operations of culture in relation to its own taxonomies is precisely to mediate or reconcile the oppositions, which are the bases of those taxonomies in the first place'.[6] Mythic structures paralleled social structures according to Lévi-Strauss, but not because myth mirrors society, but because myth and society share the commonality of an underlying structure.

This perspective structured numerous works of social anthropology (Raymond Firth, Edmund Leach, Rodney Needham), which did not necessarily share Lévi-Strauss' universalism, but analysed in many detailed studies the processes of symbolic mediation of such fundamental divisions and oppositions as nature vs. culture, female vs. male, pure vs. impure, structure vs. anti-structure (Mary Douglas, Victor Turner). The mainstream approaches of cultural anthropology, in contrast, were less influenced by the structuralist paradigms, since they were more interested in ethos and values and in the relation between form and contents of cultural symbolizations.[7]

Despite the emphasis on 'scientificity' and objectivity, elements of cultural criticism were either explicitly or implicitly inherent in those anthropological perspectives. Lévi-Strauss' critique of the Hegelian postulate of a universally valid course of history and of the necessity of the development towards a 'modern state' as well as his distinction between 'hot' and 'cold' societies, for instance, are well known in this respect. However, in the course of the anti-colonial liberation movements and the Western social movements of the 1960s, the colonialist involvements of the discipline were made a topic of anthropological debate.[8] On the one hand, this criticism led to anthropology's turning to the 'others' in one's own societies, peripheral communities and marginalized groups in 'Western societies'.[9] On the other hand, critical inquiry in the form of questioning the political-ethical implications of field research[10] and the position of anthropology in global power configurations, as well as the critique of one's one society, found its theoretical framework – not least under the influence of Louis Althusser – in structural Marxism.

In contrast to the materialist approaches of *cultural ecology*, which analysed the adaptation of cultures to their natural-material environment (Marvin Harris, Roy A. Rappaport, Elman R. Service), Marxist perspectives

emphasized the analysis of social relations in terms of structure and sought hierarchies of causes determining the functioning and the development of societies. Thus, the hierarchies of the anthropological viewpoint were displaced. Privileged explanatory value was no longer assigned to kinship organization, but especially to economic structures and modes of production. Theories of under-development (Frantz Fanon), politico-sociological analyses (Immanuel Wallerstein) and the discovery of the peasantry (Henri Medras, Teodor Shanin, Eric Wolf) highlighted the relation between centre and periphery (Jane Schneider/ Peter Schneider), the linkages between politico-economic macrostructures and the local-regional microstructures, and the consequences of capitalist penetration of societies and communities. A perspective in which the respective microcosms were regarded in isolation from the larger social context was thus abandoned. At the same time, it became evident that societies could hardly be seen as isolated, homogeneous entities with bounded identities, for they were historically constituted in mutual interaction.[11]

Despite all the differences between functionalism, structuralism and Marxism (Claude Meillassoux, for instance, criticized the 'idealism' of Lévi-Strauss' reduction of social reality to abstractions), these approaches shared the principle of a construction of structures, which preceded the analysis, and the disregard of the origin and development of those structures. The (dialectical-) analytical categories of *division, opposition and mediation* governed these theoretical constellations. The critique of such structural models, in which the individuals are inescapably locked into the objectified and insurmountable structures that determine their actions, then developed into two directions which aimed, on the one hand, at a hermeneutically guided understanding of the other and the revival of interpretative approaches and intended, and on the other hand, at making the acting subject visible again.

## SYMBOL, MEANING AND INTERPRETATION

The interpretative-hermeneutical turn in the attempt to understand different life-worlds – by Clifford Geertz, in particular – shifted the balances between the familiar anthropological concepts. In a return to the notion of 'culture' – the diffuse use of which was nevertheless criticized (by Kluckhohn, for instance) – the symbolic dimensions of social action and the interpretation of symbol systems, by the means of which human beings perceive and define their worlds, moved centre stage. Referring to Max Weber, Geertz sees the human being as 'suspended in webs of meaning he himself has spun.' Culture is such a web, and the analysis of it is 'therefore not an experimental science in search of law but an interpretative one in search of meaning'.[12] Thus, culture is not conceived of as a cognitively and abstractly ordered system of hidden structures, 'its logic [...] rather derives from the logic of organization of action, from people operating within certain institutional orders, interpreting their situations in order to act coherently'.[13] From this perspective, the world is always already interpreted, and the notion of web does not refer to structures or systems in the structural-functionalist sense, it is not an autonomous, reality-determining sphere, but a system of symbolic meanings to which human beings take

recourse in their actions. In contrast, for instance, to Victor Turner's symbolic anthropology, in which symbols function as operators in processes of social transformation (e.g. status passages), the acts of dissolving social contradictions and familiarizing the individuals with the categories and norms of society, public symbols are seen as vehicles of meanings that form the respective culture, its gestures, actions, events, etc.

This shift to a type of hermeneutics oriented towards theories of language and meaning required a redefinition of the anthropological method, which abandoned the separation of 'understanding' and 'explanation', of 'subjective empathy' and 'objective analysis' and united both moments of the research process in 'thick description'. To look at cultures from 'the natives' point of view', a demand already raised by Malinowski, calls for the interpretation of the symbolic forms – concepts, institutions, actions, forms of behaviour – through which human beings represent themselves and communicate with each other. According to the analogy between text and action, developed with reference to Paul Ricoeur, the activity of the researcher consists, on the one hand, of reading the respective cultural text: 'The culture of a people is an ensemble of texts, themselves ensembles, which the anthropologist strains to read over the shoulders of those to whom they properly belong'.[14] Inscription, on the other hand, as the textualization of actions and speech-acts of human beings, becomes the ethnographic procedure.

Another perspective developed alongside this focus on key aspects of the understanding of culture – *symbol, meaning, interpretation*. This perspective similarly rejected a view of society that denied the existence of acting subjects.

## ACTION, INTERACTION AND NEGOTIATION

The analysis of social action, the orientations of action and its meaning, and of interactions and their motivations had already been emphasized in the perspectives of symbolic interactionism (George Herbert Mead, Herbert Blumer, Erving Goffman) and of transactionalism (Bruce Kapferer) and their critiques of the Durkheimian and Parsonian paradigms of sociology. No longer the determining effect of institutions, norms and values stood in the foreground of the problematization conditioned by individual choice and decision-making on the part of the concretely acting human beings in their respective networks of relationships (Jack Goody, Frederick George Bailey, Fredrik Barth, Jeremy Boissevain).

Similarly, the 'theory of practice', as developed by Pierre Bourdieu in the form of a critique of structuralism, no longer focused on objectified structures but on human action and the strategic use of norms, values and relations, allowing for their manipulation and legitimation as well as their reproduction, thus leading to a linkage of the microanalysis of interactions to the macroanalysis of societies (Plate 97). In Bourdieu's view, social action is not undetermined, since experiences are inscribed into bodies and institutions such that a 'habitus' forms as a specific disposition to act. However, the habitus provides no blueprint for behaviour but rather a set of resources with which situations can be understood and the applicability of rules judged. There is thus always room for strategies of the

individuals; the 'logic of practice', unlike a structural model, unfolds in time and works through the judgment of situations under conditions of uncertainty about rule application.

The shift from systemic approaches and the postulate of the atemporality of objectified structures towards theories of action requires a move from synchronic-static to diachronic-processual analyses, and the emphasis on the specific acting human being brought the question of the temporal organization of actions, the temporal structuration of the life-course and the social conceptions of time and history into view. Or, in Bourdieu's words, 'Practice unfolds in time and it has all the correlative properties, such as irreversibility. Its temporal structure, that is, its rhythm, its tempo, and above all its directionality, is constitutive of its meaning.' 'To reintroduce uncertainty is to reintroduce time ... substituting the dialectic of strategies for the mechanics of the model.'[15]

The emphasis on temporality demanded a reconsideration of historicity in anthropology. Up to this point, historical contexts had largely not been conceptualized as internal processes in anthropological considerations of 'history', but as external factors. Thus, it was not the historical practices of the respective society, but the impact of Western/colonial history on that society that was analysed. At the same time, contemporaneous societies or social groups were often located on a developmental scale and in a unilinear line of progress – as 'people without history', characterized as 'tribal', 'feudal', 'early-capitalist' or 'traditional'. Thus, they were placed 'in another time' and distanced as not being coeval. More recent historical works have, however, emphasized the mutual interdependencies as well as the historical trajectories specific to the various societies, which can hardly be subjected to a universally valid model of the course of history in its Western conception.[16]

Even though *action, interaction and negotiation* stood at the centre of the analysis of culture and society in these theoretical constellations, the opposition of objectivity and subjectivity, of researcher and 'researched', of 'we' and 'other' were hardly questioned at all. Nevertheless, has the recognition of the other as a historical actor in the 'theory of practice' and the insight in the social construction of knowledge been a step in the direction of a critical reflection on the ethnographic constitution and representation of the other and the questioning of the privileged standpoint of the researching subject towards the 'object'?

## DISCOURSE, TEXT AND REPRESENTATION

The movements for liberation and 'the critique of colonialism in the post-war period, which undermined the West's authority to represent other societies, has been reinforced by an important process of epistemological questioning and reflexive theorizing about the limits of representation itself'.[17] In the course of this reflexive movement since the end of the 1960s, the anthropological research practices themselves have been made a topic in hermeneutical-interpretative and language-philosophical studies as well as in post-structural critiques of discourse.[18]

Edward Said's critical study of Western knowledge about the representation of the exotic, about 'Orientalism', demonstrated that the recognition of the other as the object

of knowledge is intrinsically tied to power. Feminist-oriented gender studies[19] contributed to the abandoning of epistemological certainties by showing that anthropological discourses took their own – male-dominated – presuppositions and representations for the characteristics of the respective society. Thus, those social relations, institutions and relations of production in which power and influence are concentrated are often conceptualized as 'the' society, excluding and rendering invisible the female as the other and locking it into a male 'general'.

In the course of such *anthropology*, it was also attempted to clarify the processes of gaining knowledge and of writing in all their aspects and to problematize the web of relations between the researcher and the other as members of different cultures. Following Michel Foucault, the relations between researchers, 'research objects' and addressees of the research are regarded as part of an encompassing relationship between forms of practices and the powerful 'politics of interpretation' (Paul Rabinow) and 'discursive formations and discursive strategies' (Michel Foucault). The search for knowledge is understood as a specific historical form of social practice, representing particular forces in society.

In this context, attention is focused on the processes of making and marking the other in time and space, the passing from coevality in fieldwork to the distancing in analysis, conceptualization and text,[20] and on the various strategies of establishing ethnographic authority as well as on the literary procedures and tropes (Hayden White) in ethnographic representations. This emphasis on the construction of the other obviously reflects one of the core problems not only of anthropology, but of scientific practices in general: the division of subject and object considered as distinct, coherent, stable and homogeneous entities, and the attempt to overcome this dichotomic separation by emphasizing the dialogical character of interaction in the research process and the shared construction of reality. In these perspectives, cultural interpretations and the interpretations of culture are located in many sorts of reciprocal contexts, obliging writers to find diverse ways of rendering negotiated realities as multisubjective, contested, power-laden and incongruent. In these views, the writings on culture and society are considered as relational, as inscriptions of performed interactions in communicative processes that develop historically between subjects in relations of power.

But even in these approaches, organized around the topics of *discourse, text and representation*, anthropological reflexion and the revision of its modes of knowledge generation appear to be reserved to those who are part of this discursive tradition. The world, or so it seems, continues to be ordered from the point of view of Western anthropologists, and particular systems of knowledge remain subordinated to the exigencies of critical metatheory.

Members of various societies have long analysed their 'own' culture.[21] Although the epistemological paradigms Lévi-Strauss once recommended in a hegemonic gesture – 'wherever populations remain physically strong while their culture rapidly veers towards our own, anthropology, progressively taken over by local scholars, should adopt aims and methods similar to those which, from the Renaissance on, have proved fruitful for the study of our own culture'[22] – are being questioned, the dominating

influence of Western disciplines and their conceptual categories, which are considered as being universal tools for cognition and explanation of social life, on the respective systems of knowledge has only recently become a subject of interest to scholars.

'Other cultures gain legitimacy only as objects of thought – never as tools of thinking ... The conditions for the participation of the non-Western anthropologist in the sociological discourse is the active renunciation of the present potential of his or her culture'.[23] 'Why cannot African concepts of society, social groups, social processes, and the like, derived from African ways of codifying reality, be used to draw our attention to other distinctive elements in the disciplinary matrix of sociology?'[24] Does the description of their 'own culture' demand of its members to distance themselves from their 'own' traditions of knowledge and to move solely within the representations and modes of writings in which they have been written about? Thus, the fundamental question of anthropology of the relation between 'self' and 'other' is posed anew, and the exploration of this relation becomes a new challenge to a mode of thought that refuses the construction of homogeneous identities and categorical differences between 'us' and 'them', 'the West and the rest' as well as the incorporation and annihilation of differences. Culture 'is not an object to be described, neither is it a unified corpus of symbols and meaning that can be definitively interpreted. Culture is contested, temporal and emergent. Representation and explanation – both by insiders and outsiders – is implicated in this emergence'.[25] If anthropology, however, is at work at the creation and conservation of interpretations, at building an archive and a library of meanings, then it is high time for those meanings and interpretations to be no longer merely catalogued but also brought to use.

# ARCHAEOLOGY

## *Andrew Colin Renfrew*

During the course of this century, it has at last become possible to construct a coherent account of the history of humankind from its origins millions of years ago among the anthropoid apes to the present-day world. Over the greater part of this period, the methods of archaeology offer the only source of information available to us, as written records only go back to about 3000 BC. The development of the discipline of archaeology has of course been furthered by the success of the important and dramatic excavations of such sites as the royal graves at Ur in Iraq or the discovery of the treasures in the tomb of the Egyptian pharaoh Tutankhamun – both undertaken in the 1920s[1] – or the discovery of the early hominid fossils in the Olduvai Gorge in Kenya and other sites in East Africa.

Discovery through fieldwork is only one part of the history of the discipline, however, and may ultimately be considered less significant than theoretical and methodological advances. The application of new research techniques, notably radiocarbon dating, has indeed revolutionized the archaeological enterprise, allowing the discovery and successful investigation of occupation sites in every part of the world. New intellectual approaches have transformed the way we think about the past and our perception of our place in it as human beings. These advances have permitted the emergence of what we may term a 'global view', allowing contemporary changes and developments around the world to be compared with one another. The story of the peopling of the Earth can be told with increasing precision, and the process by which significant developments, such as the origins of farming or the development of cities, have occurred at different places and times may be considered. In 1961, the British archaeologist Grahame Clark published the first edition of his *World Prehistory*. This constituted a landmark, for it initiated an era in which a worldwide vision, largely supported by radiocarbon dating, became possible. All these achievements were established, however, upon the solid foundation laid in the early development of archaeology during the nineteenth century.

## THE FOUNDATIONS

Modern archaeology is based upon a range of techniques. Some of these, like radiocarbon dating, are products of the twentieth century. However, the most fundamental technique – systematic stratigraphic excavation – was developed in the nineteenth century, so that by 1914 significant archaeological research was underway in many parts of the globe.[2] Already in 1859, two fundamental principles had been established: the theory of evolution was set out systematically by Charles Darwin in *The Origin of Species* and was soon applied to human culture and society as well as to the emergence of our species. The distant past of humankind was established the same year, when the flint artifacts found in the gravel quarries of the River Somme in France demonstrated that human history extended into the ice ages far beyond the traditional date of Creation, which biblical scholars had placed at 4004 BC.

## THE RISE OF ARCHAEOLOGICAL SCIENCE

The principal problem for archaeology has always centred on dating. The method of stratigraphic excavation offers a means of arranging archaeological finds into a sequence, what one may term 'relative dating', but the problem of assigning a date in calendar years – that is to say of 'absolute dating' – was the crucial one for a long time. Various techniques, relying on solar radiation, the rate at which sediments are deposited, and the supposed durations of glacial and interglacial periods, were painstakingly developed. It was not until the advent of radiometric dating – with the use of methods based upon the constant rates of radioactive decay of suitable isotopes – that reliable methods became available. For distant time periods, measured in millions of years, slow decaying isotopes are appropriate, and the potassium-argon method is one of the most important. However, for artifacts or sites of the past 40,000 years, radiocarbon dating, developed in 1949 by Willard Libby,[3] has pride of place. For the first time, it became possible to use a laboratory-based method, operating quite independently of historical assumptions about the archaeological samples in question, to assign dates to organic materials found during excavations. Finds in the Americas or in Australia could be dated on the same basis as finds in the Old World. Reliable chronologies could now be established for areas for which no written records of any

kind existed until recent eras. Fundamental changes in our vision of world prehistory emerged during the 1960s and 1970s as a result, and the 'radiocarbon revolution' enabled researchers to date the striking 'megalithic' tombs of north-western Europe, for example, far earlier than the pyramids of Egypt, which had previously been thought to have served as the model for the European tombs.

Prospecting methods, and in particular the use of aerial photography and satellite imaging, have allowed experts to discover archaeological sites much more efficiently. A series of techniques, some of which were developed in the nineteenth century, can be used to reconstruct the environment and the diet of early populations. Since the Second World War, the new discipline of archaeological science has developed, with such sub-fields as environment archaeology, geo-archaeology and archaeometallurgy. Research in these fields is now published in such specialized periodicals as *Archaeometry* and *The Journal of Archaeological Science*. Mention should also be made of the application of molecular biology, which offers promising new opportunities for archaeological science.[4]

## INTELLECTUAL DEVELOPMENTS

The great archaeological synthesizer of the twentieth century was undoubtedly the Australian-born Vere Gordon Childe (1892–1957). His first contribution[5] was to produce an overview of the development of prehistoric Europe,[6] building on the achievements of such predecessors as the Swede Oscar Montelius. In doing so, he formulated and defined the concept of the archaeological 'culture'. He saw prehistoric Europe as fundamentally influenced by ancient Western Asia, by a process which he termed 'the irradiation of European barbarism by Oriental civilization'. His second great contribution was to achieve an unparalleled understanding of farming, whose importance he was the first to emphasize in his term 'the Neolithic Revolution'. Later referring to the rise of complex society and civilization, he coined the term 'Urban Revolution'.[7]

The first of these achievements, based upon a general view of the diffusion of culture from the Near East to Europe, has not stood the test of time, and more particularly the radiocarbon revolution, although the importance of Childe's European synthesis remains considerable. The second, Childe's view as expressed in *What Happened in History* (1942), marked a turning point. It helped to inspire some of the major post-war fieldwork projects on the origins of agriculture, such as that organized by Robert J. Braidwood in Iraqi Kurdistan. Similarly, it helped to encourage research into the origins of civilization not only in the Near East but in the Americas as well.[8]

A radical re-assessment of the existing traditions of archaeological thought was undertaken in the 1960s by Lewis Binford in a series of papers published in *American Antiquity*.[9] The so-called 'New Archaeology' or 'processual archaeology', initiated by Binford and his colleagues[10] in the United States and by British and Scandinavian scholars,[11] was critical of the diffusionist thought and of the emphasis upon classification favoured by traditional archaeologists. They preferred to emphasize the processes of change operating within societies, including demographic, social and technological processes. They embraced the environmental approach offered by developments in archaeological science

and turned to the philosophy of science for an intellectual framework that was less subjective than what they sometimes described as the 'pseudo-history' of their predecessors. More rigorous, often computer-aided, analysis was one of their objectives, with an emphasis upon research design and the testing of hypotheses. Although controversial, this was, in many ways, a breath of fresh air, but the rather unimaginative application of some of these principles[12] led to objections that this approach was 'scientific' and undervalued the role of the human individual.[13] Certainly there was some justification to the criticism that the 'New Archaeology' had overlooked the importance of the symbolic aspects in human thought and action, and the last two decades of the century have seen the development of 'post-processual' or interpretive archaeologies,[14] which take a more subjective approach, avoiding what they see as the false objectivity of science, sometimes urging that archaeological research should have a motivation that is overtly political.[15]

The 'interpretive' critique of processual archaeology has certainly infused new life into the theoretical debates that have characterized archaeology over the last third of the century. However, in the eyes of some,[16] hostility towards scientific method, and emphasis on the subjectivity of interpretation can lead to a dangerous relativism where 'anything goes'. Meanwhile several specialists, continuing to work within the traditions of what can be termed cognitive-processual archaeology, have sought to explore the symbolic and cognitive devices of early societies.[17] One of the most notable features of archaeology at the end of the century is the lively nature of such discussions and the emergence of varying new approaches, including feminist archaeology.

While these debates have been most spirited in Britain and in the United States, it should be noted that the Marxist tradition in archaeology was also inherently processual rather than diffusionist, and neo-Marxist thinkers in France, Denmark and Mexico have conducted their own re-analysis of traditional archaeologies.

## THE EMERGENCE OF WORLD ARCHAEOLOGY

With the end of the colonial empires, the later part of the century has witnessed the development in many parts of the world, along with a new national awareness, of a renewed interest in the past, and particularly in the past of indigenous communities. In Africa, for instance, the artistic achievements of the kingdoms of Ife and Benin, in what is now Nigeria, are now more widely recognized as sophisticated products well worth comparison with the accomplished works of ancient western Asia or the classical world. The nation of Zimbabwe today takes its name from a major monument that dates back to before the time of European influence. Prior to independence the origins of Zimbabwe, which had been documented by Gertrude Caton Thompson in 1931, were officially denied, and a European origin was claimed on the basis of what can only be termed racist assumptions. With the passing of colonialist thought, the importance and interest of local archaeologies is much more widely recognized, and areas formerly little-explored archaeologically, such as South-East Asia, or the islands of the Pacific, are now being more intensively investigated.

Other areas, such as China, have antiquarian traditions going back many centuries. Modern archaeology, however, based on systematic fieldwork using stratigraphic excavation, began there with the research of Andersson in 1934 and has since made significant strides. Archaeology in China flourished greatly under communist rule. Indeed it has generally been the case that Marxist regimes have followed the lead given by Marx and Engels themselves in emphasizing the importance of archaeology for an understanding of the foundations of society. In the Soviet Union, there was considerable investment of resources during and after the Stalinist era, although it is fair to say that intellectual debate was somewhat restricted. Fieldwork and archaeological science, however, flourished.

Archaeology is also increasingly contributing to our understanding of those periods for which written evidence is available. This has always been the case for the ancient civilizations of Egypt and Western Asia. But the archaeology of the classical world (i.e. ancient Greece and Rome) is developing to the extent that many conclusions are now drawn as much from archaeological as from written evidence. The same is true for the medieval period in Europe, and industrial archaeology is now a well-established field both there and in the United States.

Mention has been made of research into the agricultural and urban revolutions, which we now know took place independently in several parts of the world. The problem of orientation arising from the new questions resulting from theoretical considerations is as important as the new research techniques made available by archaeological science.

However, archaeology's greatest contribution during this century has been to expand our understanding of the origins of humankind. Many of the earliest discoveries of fossil humans were made in Europe in the nineteenth century: the distinction between the two Upper Palaeolithic varieties, Neanderthal and Cro-Magnon man (our own species, *Homo sapiens sapiens*), were by then well established, and their origins in Europe are now known to date back as far as 40,000 years ago. However, the first examples of ancestral forms, initially termed *Pithecanthropus* ('ape man') and now called *Homo erectus*, came to light at the turn of the century in Java, and were followed by the discovery of 'Peking man' in the 1930s through the excavations at Choukoutien in China. *Homo erectus*, which has since been further documented by discoveries in Africa, is now known to have flourished between 1.5 million and 500,000 years ago. In 1925, Raymond Dart announced the discovery in Southern Africa of fossilised remains of *Australopithecus*, which is now recognized as a still earlier and ancestral hominid whose origins (in the form of the famous fossil 'Lucy') can be traced back 3.5 million years ago in Ethiopia.[18] The development from *Australopithecus* to *Homo erectus* has been comprehensively documented in the important excavations of Louis and Mary Leakey in the Olduvai Gorge in Kenya.[19] It now appears clear that the earliest stages in human evolution took place in Africa, and it was from there that *Homo erectus* migrated to western Asia, to East and South-East Asia and to Europe. Our own species developed from *Homo erectus*, and this process also seems to have taken place in Africa, about 100,000 years ago, although how far parallel and related developments may have been occurring in Europe and Asia is not yet fully understood.[20] With the beginning of the Upper Palaeolithic

period, some 40,000 years ago, the picture is much clearer, and it is now possible to give a reliable outline of the human colonization of the globe.[21] This new understanding of humankind's past, which is continuously being corrected and refined, and to which molecular biology is beginning to make a contribution, is one of the principal achievements of more than a century of archaeological research. It allows us to assert with great confidence the fundamental unity of the whole of humankind and to document in a detailed way the manner in which each continent and country of our world came to be peopled.

## DEMOGRAPHICS

*Tian Xueyuan*

The history of demography dates back to John Graunt, who is recognized as the 'father of demography' due to his publication *Natural and Political Observations Made upon the Bills of Mortality* of 1662. Since then, the subject of demography has developed as an independent discipline. For the last 200 years, however, demographic specialists have concentrated more on population studies from a sociological and economic perspective than on statistics. In particular, the study of demographics has been greatly influenced by Thomas Robert Malthus' *An Essay on the Principle of Population*, an immensely popular yet controversial work first published in 1798 and reprinted six times over the following 28 years. Malthus' principle of population nurtured debate between anti-Malthusianism and neo-Malthusianism, whose proponents adapted the principle to modern contexts. At the dawn of the twentieth century, the field of demographics was entering a new phase not only because of the ongoing debate over Malthus' principle but also due to successive breakthroughs in population studies.

The demographic developments in the twentieth century can be divided into two distinct periods: before and after the Second World War. The major demographic breakthroughs that occurred in the first period gave rise to the interdisciplinary character in the field after the Second World War.

### EXTENSIVE DEMOGRAPHIC BREAKTHROUGHS PRIOR TO THE SECOND WORLD WAR

Malthus' principle made such a great sensation when it was formulated in the late eighteenth century largely because of the rapid growth of Europe's population at that time. However, this situation changed substantially at the beginning of the twentieth century. Although world population was still growing in an unprecedented manner, the population birth rates and natural growth rates in Europe, and especially western and northern Europe, were decreasing, thus resulting in low population growth. It was in this context that the demographic transition theory was formed. In his article on demographic theories published in 1909 and in *Demographic Revolution* published 20 years

later, French scholar A. Landry explored population transition in his discussion of three different stages of population development. Through a different method, Warren Thompson in America reached similar results. Thompson grouped the world's population into three regional types with different fertility and mortality levels corresponding to specific transitional stages.

### The theory of optimum population

The debate over Malthusian population theory prompted some economists and demographers to ponder the crucial question of the optimum size of population. Edwin Cannan's 1914 book entitled *Wealth* is generally regarded the first publication to address the issue of optimum population. Cannan defined optimum population as the population size capable of generating the maximum industrial and agricultural return. The notion of optimum population was further developed by Carr-Saunders in his *Population Problems*. According to Carr-Saunders, the optimum population is determined by the maximum individual benefits or the highest living standard. Owing to the fact that it did not stress the issue of over- or underpopulation, the theory of optimum population enjoyed popularity in the field of demography during the 1920s and 1930s.

### Economic school

The demographic factors were generally dealt with as dependent variables in the theories of classical economics and 'vulgar economics'. It was not until the early twentieth century that some economists began to deal with demographic factors as independent variables of economic growth, which represented great progress. John Maynard Keynes, author of the landmark work *The General Theory of Employment, Interest and Money* (1936), was perhaps the most influential figure in this period. Keynes argued that the economic crisis and depression of 1929–33 was caused by insufficient effective demand, which in turn was determined by such factors as population, consumption level and technological composition of capital. Moreover, he believed that decreasing population growth rates were critical to reach sufficient

effective demand. Keynes thus explained the determinant role of population factors in economic development, which also constituted a part of his 'stagnant economy'. American and British economists A. B. Hansen and R. F. Harrod developed Keynesian ideas further within the influential economic school of demography.

### Sociological school

During this same period, population studies from a sociological perspective also made great breakthroughs. In his theory of 'social capillarity' (*la capillarite sociale*) proposed in the early twentieth century, French sociologist A. Dumont explained that the individual's pursuit of self-development was linked to his desire and that so-called social capillary action was conducive to the decline of fertility. During this period, the diverse approaches by sociologists in their analyses of demographic issues greatly encouraged studies on the themes of fertility, population transition and optimum population.

### Mathematical school

For about 200 years, demography, as the study of statistics, had made no revolutionary breakthrough until the early twentieth century, when A. J. Lotka formulated his stable population theory and Raymond Pearl and Lowell J. Reed rediscovered the logistic curve. By mathematical deduction, Lotka worked out a basic formula for a stable population model and demonstrated the need to achieve stable age structure in a closed population in the case of constant age-specific fertility and residual death rates, providing the reproductive term is sufficiently long. By explaining the S-shape curve of population change from low to high and back to low growth, Pearl and Reed resurrected the logistic curve idea elaborated in the nineteenth century and thus provided a new methodology for exploring population transition using mathematics and statistics.

## POST-WAR DEVELOPMENTS – INTERDISCIPLINARITY

Demographics in the period following the Second World War adopted an interdisciplinary approach on the basis of breakthroughs made in the first half of the century. After the war, world population growth accelerated due to the baby boom. The problems of poverty, unemployment, famine and pollution became so serious that Malthusian population theory was resurrected. Two proponents of neo-Malthusianism, F. A. Pearson and F. A. Harber, published a series of works on the themes of world hunger and the global population crisis in the 1940s. In the 1970s, pessimistic population theory expounded in works such as *The Doomsday Book* by G. Taylor and *Limits to Growth* by D. H. Meadows et al. were influential.

### 'Demographic transition theory'

On the basis of the work of A. Landry and W. Thompson, American demographer F. W. Notestein constructed the theoretical model of population transition described in his publications *Population: The Long View* and *Economic Problems of Population Change*. The population transition theory attained worldwide recognition through the *Population Growth and Economic Development in Low Income Countries* by A. J. Coale and E. Hoover, who applied the theory to developing societies.

### Progress in economics of demography

The relationship between population change and economic development has been a focus of demography since the field's inception. New advances in the economics of demography since the Second World War were made at both the macro and micro levels. At the macro level, the outstanding contemporary demographic economist J. J. Spengler analysed the relationship between population and food supply in *Economics and Demography*, published in the 1950s. He stressed the need for population growth control by arguing that a population increase would lead to serious problems related to food, land, water and mineral resources given the increased demand for food resulting from higher income. The introduction of development economics opened up a new field in the economics of demography. In his studies on the relationship between population and economic growth in developing countries, Coale emphasized the influence of population on economic growth by arguing that savings and investment must grow by an annual rate of 3 per cent if population growth rates remained 1 per cent, given a of capital input-output ratio of 3:1. W. A. Lewis developed demographic macroeconomics by placing such factors as population and labour into a framework of modern development economics in his analysis of the shift of labour from traditional to modern industries.

At the micro level, H. Leibenstein constructed his theory of children's costs and benefits by classifying the costs as direct or indirect and by dividing the benefits into six categories, e.g. labour-economic and consumption-enjoyment benefits. In exploring children's costs and benefits among families of different social levels, Leibenstein explained the process of the decision to reproduce. In his analysis, G. S. Becker introduced the concepts of invariable or quantity costs and variable or quality costs. Moreover, he attempted to prove that the substitution between the quantity and the quality costs and the general law of increasing quality require flexibility. It was this law that expressed the necessary shift of investment from quantity to quality costs, which ultimately determined fertility decline. Other noteworthy concepts in demographic microeconomics are R. A. Easterline's theory of children's supply and demand, the 'inter-generation inflows of property' by J. C. Caldwell, and 'household economics' by T. W. Schultz.

### Formation and development of sociological demography

The population studies from a sociological perspective such as the 'social capillarity theory' did not result in the formation of sociological demography in the period after the Second World War. At that time, many sociologists

interested in the field of demography, such as K. Davis and P. Hauser, tried to provide sociological explanations for population size, quality and structure. In the 1960s and 1970s, Davis addressed the issue of population and stability and the relationships between population and urbanization in his analysis on the themes of 'population urbanization' and 'crisis in world population.'

## Development of mathematical demography

Owing to the extensive application of mathematical methodology, demographers improved their traditional methods by means of computer technology. As mathematicians and scientists in systematic dynamics began working or collaborating in the field of demography, mathematical demography as an interdisciplinary subject developed. Thanks to the methodological revolution in demographic data collection and modification, population projection and demographic quantitative analysis, mathematical demography greatly facilitated the overall development of demography and the formation of an overall demographic system.

## Studies on population and sustainable development

Studies on population and sustainable development have a long history. Many theoretical models on population, food, resources, environment, and social and economic development were constructed by quantitative methods of systematic dynamics in the second half of the twentieth century. One noteworthy example is *Limits to Growth* by D. H. Meadows, published in 1972, when the concept of 'sustainable development' was first put forward at the World Conference on Environment held in Stockholm. A report of the World Commission on Environment and Development, *Our Common Future* (1987), popularized the notion that development is sustainable only if 'it meets the needs of the present generation without compromising the interests of future generations'. Since the United Nations Conference on Environment and Development (Rio de Janeiro, 1992), the International Conference on Population in (Cairo, 1994) and the World Summit for Social Development (Copenhagen, 1995), 'sustainable development' has become one of the most important topics at the beginning of the twenty-first century. Thanks to the critical role of population in sustainable development, studies on such topics are being undertaken in many countries.

In the twentieth century, demography gradually became a discipline with its own specific objects, methodology and scope. The current system of demography includes a range of independent sub-disciplines such as demographic statistics, the economics of demography, sociological demography, population geography, development demography, and mathematical demography. Since development is an ongoing process, there is no doubt that demography will progress further alongside social and economic development and advances in science and technology in the twenty-first century.

# SOCIOLOGY

*Peter Wagner*

## SOCIOLOGY STRUGGLING TO BE BORN

The unique status of sociology among the social sciences can be attributed to the fact that there is no realm or aspect of social life in which sociologists can claim specific competency. At the beginning of the twentieth century, when most of the other social science disciplines discussed in this chapter were relatively well established, sociology was still struggling to come into existence.

L'Institut International de Sociologie (IIS) was founded in Paris in 1893, and at about the same time Emile Durkheim set out his methodology in *The Rules of the Sociological Method* (Plate 98). Similar but less successful treatises for the new discipline as well as overviews of its development were published in many European languages in the closing decades of the nineteenth century. Several national associations were formed shortly after the turn of the century, e.g. the American Society for Sociology (1905), the German Society for Sociology (1909), the Society of Japanese Sociology (1912) and its more liberal counterpart, the Japan Sociological Society (1923), and the first Petrograd-based Russian Sociological Society (1916). But this flurry of new activity could not hide the fact that this newcomer was often perceived as an upstart by academic institutions. Consequently, its somewhat unwelcome arrival on the scene was often obstructed. The University of Oxford, for instance, considered the teaching of what came to be known as the social sciences to be the exclusive domain of 'philosophy, politics and economics'. And in Italy, Benedetto Croce spoke for many philosophers when, in 1906, he called sociology a 'chaotic mixture of natural and moral sciences ... a new science, which is unjustifiable as a philosophical science and nothing new as an empirical science or anything else. It is new only as "sociology", that is as a barbaric positivistic incursion into the domains of "philosophy and history"'.

What was at issue when the field of sociology was defined? Sociology studied contemporary Western society; it did not claim special expertise concerning the past, as did history, or concerning other societies, as did anthropology. Moreover, sociology could not claim any field of analysis directly comparable to the relations of production and exchange as for economics, to the modes of setting and implementing common rules as for political science or to the workings of the soul in the case of psychology. As a consequence, some sociologists, like Emile Durkheim, boasted that they provided the most comprehensive study of all social relations, subordinating all other fields. More modest sociologists endeavoured to complement the substantive fields of inquiry by studying the actual form of social relations, as Leopold von Wiese in Germany. The former claim invariably aroused opposition from scholars of more established disciplines, and the latter, while more acceptable, could hardly be considered very appealing.

Both Durkheim's and von Wiese's characterizations of sociology already addressed the issue in the terms of academic institutions and disciplines, and they formulated proposals for entry into the universities. To fully understand the contested nature of sociology as well as the expectations and the fears that it provoked at the end of the nineteenth century, we must examine sociology in broader terms. Although the discipline appeared in the twentieth century, the formulation of its ambitions dates back to the early nineteenth century.

### The promise of sociology: understanding 'modern society'

The emergence of sociology can be traced back to the period immediately following the American and French revolutions. This discipline is decisively marked by liberal thinking since it does not take social order for granted and does not consider it endowed by some superior extra-human authority. At the same time, however, it breaks with the liberal political philosophy of the seventeenth and eighteenth centuries by insisting that there is a social reality between individuals and the polity. From a sociological point of view, political order cannot be understood as the result of some agreement between atomistic individuals; its form and substance rather is related to a structure of social relations; the task of sociology is to identify and analyse that structure.

Thus, sociology marked its difference from economics and psychology, on the one hand, and political science and law, on the other, less by carving out a specific realm of social life than by developing a distinctive perspective. It

focused on sociality as a human characteristic and on the emergence of society, defined as a structured set of social relations between human beings. This phenomenon was neither the inadvertent result of multiple independent preferences nor identical to the formal set of common rules known as law and institutionalized in the state.

To frame the issue in such terms meant that sociology was 'modern' in the sense that it accepted the assumptions and outcomes of the revolutions: human action, being autonomous, could not be subjected to imposed laws. Consequently, human social life developed along novel paths and broke with earlier human societies. But this did not imply that the new situation was basically well grasped by individualist liberalism or that it was unknowable because of the unpredictable nature of autonomous action. In contrast to both these views, sociology proposed to make the new set of social relations intelligible through the study of social relations and the emergent social order. In this sense, sociology posed as the science of 'modern society' per se, with its own very distinctive programme.

At this point, it should also be noted that sociology, thus understood, is indeed a 'Western' discipline, at least in historical perspective, for it originally emerged in Western Europe and the United States. Even the early followers elsewhere, in Russia or Japan for instance, referred to Western examples. In some areas, however, forms of sociological thought emerged strongly and addressed the liberal heritage in critical terms, by proposing organismic or other holistic views of society. This was notably the case in Germany, the United States and in Japan, where authentic responses to 'Western' modernity were sought. Furthermore, the original programme itself was transformed during the twentieth century, and in the process, sociology's original problematic was mitigated. But even these developments cannot be understood if not placed in historical context.

Though not referred to under the name of sociology, a term coined by Auguste Comte in 1838, the outlines of this programme were identifiable early in the nineteenth century, most clearly in Hegel's *Elements of a Philosophy of Right*. During the first half of that century, however, it could hardly assert itself against the 'old' state sciences on the one hand, and the 'new' political economy on the other. During the second half of the nineteenth century, in contrast, under the influence of evolutionist thinking, many of the questions sociology posed seemed to have already found answers in a broadly determinist perspective on historical progress. The work of Herbert Spencer is the most important case in point. It was only towards the beginning of the twentieth century that the project of sociology as a research programme and a discipline was revived.

## 'CLASSICAL SOCIOLOGY' – AN EPISTEMOLOGICAL, POLITICAL AND INSTITUTIONAL PROJECT

The early twentieth century was not only marked by the creation of sociological associations and programmatic treatises: it is also now known as the period of *classical sociology*, the era of the discipline's founders, most notably Emile Durkheim and Max Weber (Plate 99), but also Vilfredo Pareto, Georg Simmel, Charles Horton Cooley and George Herbert Mead among others. Not all of these scholars were regarded as key advocates of the discipline in

their lifetimes, and to some extent this period's recognition as a classical phase occurred after the event, not least through Talcott Parsons' 1937 work *The Structure of Social Action*, which pointed out similarities between those scholars and claimed that their theories actually converged – unknown to the authors themselves – on a sociological theory of human action. Regardless of the validity of this particular claim, the works of the 'classical' period were held together by at least two common problematics: an epistemological and political one.

Around the turn of the century, academic debate was marked by an acute awareness of a deep-rooted crisis of science – despite, or perhaps because of, the enormous development of the sciences during the nineteenth century. Ernst Mach's logical positivism, Wilhelm Dilthey's separation of the models of the natural and the human sciences, and Friedrich Nietzsche's radical critique of science were among the most profound European expressions of these doubts. In the United States, William James and Charles Peirce developed the pragmatist response to similar doubts, a response that appeared to lead the way to further scientific activity. Regardless of the particular context and position taken, the classical sociologists addressed the issue of the possibility of social knowledge in their extensive writings on epistemology, ontology and methodology. The major sociological approaches that still exist today emerged from these works. An early statistical-quantitative approach to social causality can be traced to Durkheim's study of suicide and the works of Durkheimians like François Simiand. Interactionist-qualitative analyses of social relations have their origins in Georg Simmel's observations of social life in Germany as well as in social psychology and theories of the self expressed by George Herbert Mead and the Chicago School in its later works. Historical and comparative studies of institutional and cultural constellations and developments owe much to the work of Max Weber.

In this sense, the so-called founders can justifiably be seen as laying the groundwork for the development of sociology as a discipline in the social sciences. And their efforts were also honoured by some, albeit modest, institutional success in establishing sociology in the universities. In the United States, the early sociological work took place in a context of university expansion and creation. It was thus comparatively easy to secure a place for a new field. In France, Durkheim's very conscious efforts resulted in a 'halfway failure'. He succeeded in establishing hegemony for his 'French school of sociology', as it was later called, among the competing social science approaches, but after his death the dominance of philosophy at French universities reasserted itself at the expense of sociology, which had to wait until the 1950s to be recognized as a degree subject. In Germany, authors, including Weber, were reluctant to use the term *sociology* with its taint of abstract Enlightenment thinking because it was often considered alien to the German mind. The political upheaval of the First World War and the end of imperial Germany, however, paved the way for the introduction of the study of contemporary society and its problems – even if only peripherally as advocated by von Wiese – at universities, including those recently founded such as in Cologne and Hamburg. A similarly rapid institutionalization occurred in Poland during the interwar period.

However, there is more to observe in this so-called process of founding a discipline. As mentioned above, the

early sociologists did not only share an intellectual context critical of science but also a political context that can broadly be defined as a crisis of liberal thought in an emergent industrial mass society. During most of the nineteenth century, in the wake of the democratic revolutions in the United States and in France, liberalism and liberal theorizing occupied centre stage in intellectual debates on politics. At the end of the century, however, intellectuals were generally well aware of the failure of liberal theory, in politics as well as in economics, either to understand the changes in societal practices or to provide criteria for their regulation.

In those *fin-de-siècle* debates, the classical sociologists agreed that societal developments had superseded classical liberalism but insisted that revisions had to be made within that political tradition. They viewed the contemporary situation as one in which a major political restructuring was occurring without a clear objective or guiding vision. They turned this into their major theme: incapable of adhering to the idea of a quasi-automatic regulation of social conflicts but unwilling to move completely away from the tenets of bourgeois liberalism, they devoted their analytical efforts to searching for those phenomena that might provide for the sustainable development of society.

Theories of *organic solidarity* and the relationship between religion and morality in Durkheim, between forms of legitimate domination and *charisma* in Weber, between the political class and the *circulation of elites* in Pareto were the results of such attempts at redefining orderly relationships between extended social practices, uprooted social identities, and polities in need of adaptation. Classical sociology provided important components of a possible diagnosis of the period's major social transformations.

It has also to be noted, however, that the emphasis on sociology to make an intellectual contribution to a political restructuring was not to be had without a price. What came to be known as sociology was only one part of a broader intellectual domain that addressed the crises of knowledge, self and politics in a variety of ways, and many sociologists were well aware of the bridges between their emerging field and literary discourses and critical debates in philosophy and psychology, in particular the theories about knowledge, history and the self expounded by Henri Bergson, Friedrich Nietzsche and Sigmund Freud, to name only a few outstanding figures.

Despite their familiarity with and appreciation of such related discourses, early sociologists were largely responsible for isolating their emergent discipline from them. To varying degrees, they built barriers around their own work. Different explications can be advanced to explain why this was done: in epistemological terms, to fend off strong doubts about the feasibility of social science; in political terms, to focus on a possible restructuring of the polities rather than to open possible paths towards less desirable political outcomes of the ongoing social transformations; and in institutional terms, to secure a place for the new field in the universities rather than to allow their own thinking to merge with other approaches under broader headings such as philosophy or history.

**Divergence between the two world wars**

As in many other areas of social life in Europe, the First World War marked a major break in the development of sociology. Durkheim died in 1917, Weber in 1920 and Pareto in 1923. Coincidental as these dates are, it is indicative of a broader intellectual shift that, even though these 'founders' continued to be widely quoted after their deaths, their work did not leave a strong imprint on intellectual debates between the two world wars. This fact can partly be interpreted in political terms since the classical sociological reappraisals of the liberal tradition were no longer convincing. Within the larger crisis of the liberal utopia, the manner of understanding society by classical sociological means was seriously called into question. While the classical period had been marked by a broadly parallel development of sociology in Europe and North America, an intellectual divergence between those two regions occurred in the interwar period, and the temporary demise of the sociological project as it was conceived by the founders developed only in Europe.

In Europe, sociological discourse fell to pieces. The deliberations on a theory of action were taken up by highly voluntarist philosophies of action, often referred to as *philosophy of the deed*. What was later to be called *empirical social research* developed a practical orientation towards the use of information on people's opinions and behaviour and often remained on the fringes of or outside academia. These aspects of the 'broken' discourse came to flourish under the fascist and totalitarian regimes. Philosophies of action underpinned the idea of a strong man and the will and power to rejuvenate the nation. Empirical social research was often specifically organized to acquire strategically useful knowledge about the state of the population. But both pieces flourished separately. Taken together they might have formed an empirically supported social theory of collective action that could have been inscribed into a normative theory of democracy.

Elements of such discourse existed in the United States. If the political philosophy of John Dewey is linked to the social theory of George Herbert Mead and the empirical sociology of the Chicago School, there emerges a body of theoretical and empirical knowledge that emphasizes the human ability to create and recreate one's own life individually and collectively. But such pragmatist and interactionist sociology also did not become the dominant approach in the United States; American sociology experienced an intellectual divide similar to the European one, though much less tumultuous.

The hegemony in American sociological research shifted from the Chicago School in the 1920s and 1930s, to the Columbia School in the following decades, to social policy research in the 1960s. This shift reflected the increasing influence of factors external to academia itself. The Chicago School's urban sociology was oriented towards local social problems, defined by the researchers themselves. During the 1940s, Columbia sociology was largely driven by a demand for data by corporate actors, not least radio companies asking for listener's surveys. The Bureau of Applied Social Research at Columbia, created by the Austrian émigré Paul F. Lazarsfeld, brought major institutional and scientific innovation. This institute devoted to commissioned research, or 'administrative research' as Lazarsfeld called it, focused on large-scale surveys to be analysed by increasingly sophisticated statistical means. Social policy research in the 1960s then transposed this research model into the realm of national science with the federal state acting as a powerful research instigator. The

shift of criteria for research design and topics resulting from this move towards commissioned research has also become known as *epistemic drift*.

Sociological theory in the United States, in contrast, developed somewhat on the sidelines of these research shifts. Talcott Parsons became the towering figure in the theoretical 'modernization' of the social sciences. After having tried to re-appropriate the classical European heritage by showing the relevance of those works, Parsons gradually worked these selectively appropriated ideas into a theory of modern societies as systems differentiated into functionally related sub-systems working as an integrated system. He thus claimed to have solved a key problem of sociological theory, namely to be able to deal with entire social formations while at the same time accounting for the rationales of human action.

In the United States, sociological theory and empirical sociological research had become distinct fields in much the same way as it had in Europe. However, in contrast to Europe, where the institutionalization of sociology was very limited, in America, both fields continued to be considered under the umbrella of sociology. It is within this context that some sociologists proposed a new linkage between the two. For example, in the 1950s, Robert Merton called for middle-range theories that were less comprehensive than Parsonian systems theory but compatible with it and capable of being refuted or underpinned by empirical research.

## GLOBALIZATION AND AMERICANIZATION AFTER THE SECOND WORLD WAR

This divergence in the evolution of sociology in Europe vs. the United States formed the backdrop for the discipline's revival after the Second World War under American hegemony. Again, this situation cannot be understood without considering the political context. The failure of Europeans to safeguard democracy could be linked to their lack of knowledge about the structures and problems of their societies. Their own social philosophies had proven to be insufficient, and perhaps sounder knowledge based on empirical sociological research could have helped to recognize social tensions at an earlier stage.

Such had been the vision of American foundations such as the Rockefeller and the Ford foundations, which had provided support for research between the wars. After the Second World War, the latter foundation stepped up its activities, some of which involved émigrés such as Paul Lazarsfeld in establishing a solid infrastructure and receptivity for empirical research in their countries of origin. With the support of UNESCO, raising public awareness of the modern approach to sociology became an objective of global dimensions. The foundation of the International Sociological Association (ISA) in 1949 marked an important step towards this goal, as it became the second worldwide association of sociologists. The IIS continued to exist but had fallen into disrepute at the end of the war owing to the fascist leanings of some of its spokespersons.

A loose but rather widespread consensus about the form and nature of the modern approach to sociology emerged in favour of Robert Merton's synthesis of predominantly quantitative empirical research as developed by Lazarsfeld,

and a Parsonian social theory of societies as functionally interrelated systems. During the 1950s and 1960s, many national sociological communities brought forth their own quantitative methodologists and functionalist theorists. This conception of sociology demonstrated considerable epistemological optimism as to the manner of apprehending the social world and certainty in the well-ordered nature of society. In this respect, it provided a strong conception of sociology that would soon be criticized. At the same time, this new approach made sociology enormously appealing in the wider intellectual environment as well as among political elites.

The attractiveness of sociology had a double effect. First, the discipline was considerably expanded at universities, which in many countries underwent general rapid growth in the same period. Under the theoretical and methodological umbrella described above, there emerged a great number of sub-disciplines dealing with particular aspects of society, such as industrial sociology, sociology of the family, sociology of science and sociology of religion among others. Second, sociology's perceived potential to contribute to solving social problems led to a rapid increase of commissioned research, often directed towards issues of national policymaking.

*Critical theory* has become a term for a type of social philosophy broadly inspired by German idealism and which rejects empiricism because it accepts the appearances of the actual world as a totality without considering the possibility of a wider realm. While this is a valid argument, critical theorists appear to have inadvertently accepted the mainstream sociological image as an adequate representation of the 'administered society' of that time. Similarly, structuralism and systems theory are in basic agreement with functionalism about the well-ordered and intelligible nature of society; they merely add the idea of contradictions and tensions within the structure to an otherwise pre-established representation.

After accepting sociology in the Soviet Union soon after the Revolution, the official viewpoint in socialist societies (until the Communist Party congresses of 1956 and 1963) considered sociology a bourgeois ideology that hid the class nature of capitalist societies and explained societal developments less satisfactorily than Marxism-Leninism. Beginning in the late 1950s, however, sociological institutes and departments were created in the USSR, the GDR and other socialist states. In Latin America and elsewhere, sociological work during the 1950s and 1960s was dominated by theories of development as a sub-field of the sociology of modernization. Consequently, the sociological theory and research as developed in the United States had no serious challenger around 1960.

## PLURALIZATION, ACTOR ORIENTATION AND CONSTRUCTIVISM AFTER THE 1960s

The 1960s marked the heyday of the quantitative expansion and social importance of sociology, but it was also a period of major new changes. Given the structures of post-war sociology as described above, these changes appeared in the form of contestations, partly as outright rebellions, against the prevailing intellectual, institutional and political hierarchies. Together they mark the end of any intellectual

hegemony and the gradual emergence of a revised sociological project characterized by plurality and reflexivity. These developments can be grouped into three main categories.

First, the universality of the hegemonic structural-functionalist theories were called into question. Arguably, this was a Western, if not specifically American, approach, which could and should not be directly applied to other societies. Even though the goal of universal knowledge was not necessarily doubted, sociological knowledge had to be placed within the various cultural contexts from which it emerged and to which it applied. Consequently, the cultural and intellectual diversity of the sociological project was underlined, even in some parts of Europe, where it originated.

Secondly, a related criticism was directed against the emphasis on *order and systemic reproduction* in the dominant school of sociology. Initially, this debate involved what was then called consensus and conflict-oriented approaches to sociological theory. By the late 1960s, some sociologists argued that growing unrest in society would prove the failure of functionalist theory and prefigure a crisis in sociology (Alvin W. Gouldner, Franco Ferrarotti). During the 1970s, a number of alternative approaches were developed, the most important of which focused on: communicative interaction instead of systemic regulation (Jürgen Habermas); structuration in action instead of structural constraint (Anthony Giddens); logics of practice instead of structural models (Pierre Bourdieu); and social movements instead of societies (Alain Touraine). In sum, they argued in favour of a renewed emphasis on action and communication instead of structure and function in sociology.

Thirdly, there emerged a questioning of any a priori assumption on the superiority of sociological knowledge over 'lay' knowledge. From the argument that human beings construct the social world through interaction, it followed that sociological knowledge is also a social construction, created by reflexively drawing on 'everyday' knowledge that social actors themselves possess. A similar epistemological stand on reflexivity or on the inevitable 'double hermeneutics' can be found in all the major theoretical statements of the 1970s and 1980s. Exerting hardly any strong direct influence until recently, the philosophy of sociology went hand in hand with the 'strong programme' in the sociology of scientific knowledge, which called for 'symmetry' in the study of science and other social practices, and the 'linguistic turn' in philosophy, which emphasized the analysis of philosophy and science as language games that were not a priori distinct from other social languages.

### The end of 'the social' and sociology

At the end of the twentieth century, this period of contestation seemed to have come to an end. The demands of the challengers have not generally been accepted. Much empirical work in the disciplinary sub-fields proceeded as previously. Policy-orientated sociological research continued to be commissioned, though the withdrawal of the state from a strongly interventionist self-understanding reduced the demand for such social knowledge. In theoretical sociology, new perspectives were added to the existing set of approaches rather than replacing them. Some advocates of the more conventional approaches remain unconvinced of the criticisms, whereas others accept at least some of them,

but argue that any important conclusions drawn from them would incapacitate sociology's ability to conduct societal diagnosis.

Nevertheless the overall consequence of the critical approaches has been to increase legitimate doubts about the very possibility of representing society by any straightforward sociological means. This fact accounts in part for sociology's having lost much of its intellectual appeal of the 1960s and 1970s. The understanding of human sociality and the comprehension of society are in danger of getting lost amidst the competing approaches of political philosophy, individualist theorizing and cultural studies. We seem to be witnessing a repetition of the situation that arose at the beginning of the twentieth century when emergent sociology strove for a legitimate intellectual place.

At this point, we must recall sociology's original goal of promoting the comprehensive study of contemporary society. This project resulted from a historical reality: its initial point of reference can be traced to the political revolutions at the turn of the eighteenth century, and it took its 'classical' shape when the nascent societal configurations were transformed into industrial societies and nation-states. The recent emphasis on reflexivity and the linguistic nature of the sociological representations themselves should not be seen as an abdication of that project but rather as a critical scrutiny of the founding assumptions of sociology, i.e., those dating from the period around 1800 as well as those from the classical era at the beginning of the twentieth century.

In such a perspective, analyses of the discourses of the human sciences and of the construction of categories, including key sociological categories, have been put forward. Other works have explicitly focused on the nineteenth-century 'invention of the social' and the construction of the sociological viewpoint (Pierre Manent). Such works, rather than harmful to the sociological enterprise, are absolutely necessary, in particular during periods of major social transformations. Just like the writings on the philosophy and methodology of sociology during the classical period, they are prolegomena to a reconstitution of the sociological project under contemporary conditions of sociality and structures of social relations.

# ECONOMICS

*Claudio Sardoni*

The period from the mid-1920s to the outbreak of the Second World War was qualified as 'the years of high theory' by British economist George Shackle owing to its tremendous spirit of creativity and innovation. During this period, marginalist methodology was fully articulated by L. Robbins in 1935 emphasizing the positive rather than normative character of economics as a science. In addition, several significant analytical innovations took place. Such was the richness and creativity of the inter-war period that it can be said without exaggeration that almost all themes and issues dealt with by economists during the second half of the century were anticipated during this period. In this chapter, we will examine the developments in a number of fields beginning with the initial significant contributions before the Second World War.

## FROM PERFECT COMPETITION TO OLIGOPOLY

In the mid-1920s, P. Sraffa set out to develop a radical critique of the foundations of the Marshallian theory of value. However, the full implications of this critique were not appreciated until the 1960s. At that time, the profession was more interested in some considerations of Sraffa concerning the kind of markets in which firms are assumed to operate.[1] Sraffa suggested that a realistic analysis of firms' behaviour had to be carried out by considering that they operate in 'imperfectly competitive' markets. Each firm and the goods it produces differ owing to so-called 'imperfections'. In this schema, each individual firm, though small with respect to the size of the industry, is a sort of monopolistic producer and able to influence prices. Many economists took up Sraffa's suggestions and set out to develop the analysis of imperfect competition in a more systematic and formalized way. Harrod, Robinson and Chamberlin were the principal protagonists of the debate on imperfect competition, which shifted analytical attention from the industry as a whole to the individual firm in its process of decision-making. It also brought about an increase in the degree of formalization of economic analysis.

The interest of the profession in the problem of market forms in the 1930s was soon superseded by new concerns. After the war, economists renewed their investigation of this problem, even though attention was now focused on oligopoly rather than imperfect competition. Oligopolistic industries are characterized by the existence of barriers preventing the entry of new firms and by a significant degree of strategic interdependency among the existing firms. One line of research[2] is concerned with the industrial structure and the problem of barriers; others have concentrated on strategic interdependency by using the technique of games theory extensively.[3] A number of economists including Steindl, influenced by Marxism and Kalecki, have argued that oligopolistic industrial economies tend to stagnation as growth and technical progress are hindered by the lack of competition.

## THE MEASUREMENT OF UTILITY AND WELFARE ECONOMICS

Marshall's theory of consumption was based on the hypothesis that utility can be measured in cardinal terms. In the mid-1930s, this hypothesis was abandoned and a new approach to the analysis of consumer behaviour was provided. By drawing on earlier contributions by Edgeworth, Pareto and Slutsky, J. Hicks and R. Allen presented a new theory of consumption, which did not require the measurability of utility in cardinal terms; it suffices that individuals are able to rank different levels of utility in ordinal terms. This hypothesis is sufficient to ensure the existence of a downward sloping demand curve for any good with respect to its price and for any given level of income.

Consumer theory deals with individuals who aim to maximize their welfare; it has, however, implications for the notion of the welfare of the society as a whole. In so far as utility is assumed to be measurable in cardinal terms, the problem of maximizing the social welfare is relatively simple. The sum of individual utilities is the social welfare that must be maximized. Once utility is measurable in ordinal terms, the notion of social welfare becomes less obvious. Pareto,

who had refused the notion of cardinal utility, offered an alternative notion of maximum social welfare: the economy attains this optimum position when, by moving from it, it is impossible to make any single individual better off without making someone else worse off. Pareto also demonstrated the correspondence between the economy's equilibrium and the maximization of welfare.

In the 1930s and 1940s, Pareto's approach was further developed by a number of economists such as Bergson, Hicks, Kaldor, Scitovsky, Lange and Allais. Some introduced a more general definition of Pareto optimality: in order for an optimum position to be realized, it is not necessary that any individual be made worse off; it suffices that those who are made better off have enough resources to compensate those who have lost out. Others dealt with social welfare by using a so-called social welfare function, which, in ordinal terms, specifies the society's preferences. After the Second World War, the consumer theory was further developed by introducing uncertainty in the consideration of consumers' decisions and also by adopting an approach no longer based on indifference curves but on the notion of revealed preferences that avoids concern for the psychological aspects of consumers' decisions.

If Pareto-optimal equilibria are more than one, a problem of social choice arises: the society must decide which configuration it prefers. In democracy such decisions are normally made through voting. However, it has been shown that the majority principle does not guarantee a unique definition of the society's best-preferred outcome. Arrow and Sen have made important contributions in this field by showing rigorously that there is no logical way to arrive at a univocal definition of maximum social welfare.

## PLANNING AND SOCIALISM

Marxism claimed the superiority of socialism over capitalism; the socialist experience in the Soviet Union was seen as an experiment to build a more efficient and just society based on socialist planning rather than on the market. In the 1920s and 1930s, economists like Mises, Hayek and Robbins argued that either a planned economy performs irrationally because of the lack of the market or planning is impossible because of the enormous amount of knowledge and accounting that it requires. Only free markets, through the price mechanism, can ensure the rational and efficient working of the complex system by providing all the necessary information for the optimal use of scarce resources.

Others responded to these criticisms by arguing either that the problems connected to the determination of prices for an optimal allocation of resources could in fact be solved by socialist economies[4] or that the problem of rational allocation is not the crucial concern of planned economies, which mainly deal with the promotion of accumulation and growth.[5]

The difficulties of planning have been the focus of economic theory in socialist countries. In the early phases of the socialist experiment, the main emphasis was placed on planned accumulation and growth. Subsequently, with attempts to reform socialist economies, more attention was paid to the problems of efficient allocation of resources by allowing the market a greater role.

## KEYNES AND THE KEYNESIAN REVOLUTION

All marginalist economists shared the faith in the ability of the economy to ensure the full utilization of all available resources through the free working of the market mechanism. Unemployment could only be a temporary phenomenon due to factors preventing the economy from employing all those who wished to work. Excessively high wages were generally viewed as the typical cause of unemployment. The depression of the 1920s and 1930s showed that market economies could experience mass unemployment without any apparent tendency to recover. In this context, Keynes set out to develop a theory that broke radically with the past tradition (Plate 100).

Keynes's *A Treatise on Money* (1930) marked an initial departure from the dominant paradigm. In this publication, Keynes arrived at original results that gave a foretaste of *The General Theory*. The analytical centre-stage of the book is taken up by saving and investment decisions, which are made by different sets of agents and, hence, may diverge from one another. According to Keynes, it is the divergence between saving and investment, rather than changes in the quantity of money, that makes prices change. If an increase in the economy's propensity to defer consumption is not accompanied by an equal increase in the entrepreneurs' propensity to invest, the economy undergoes a process of economic crisis and falling prices.

After its publication, *A Treatise on Money* was widely criticized, in particular by some of the closest colleagues and disciples of Keynes in Cambridge. These criticisms sparked a period of intense discussion, which eventually led to the publication of Keynes most influential work, *The General Theory of Employment, Interest and Money* in 1936. The group of people who regularly met in Cambridge to discuss the issues related to Keynes's work was known as 'the Circus'. Keynes's principle of effective demand can be expounded as follows. Any increase in employment creates an increase in aggregate output and, hence, in income. The increase in consumption engendered by the increase in income is less than proportional because people normally save a certain share of their income. Therefore, in order for the whole output to be sold, an additional source of demand must be found. This additional demand is the amount of current investment, which is equal to saving, so that the excess of total output of what the community chooses to consume is absorbed. Thus, the equilibrium between aggregate demand and supply crucially depends on investment. The amount of investment depends on what Keynes called the 'inducement to invest', which, in turn, is determined by two factors: the expected profitability of investment and the current rate of interest. Investment is pushed to the point at which the marginal efficiency of capital is equal to the rate of interest. The relationship between the level of aggregate investment and the level of aggregate output and employment was established by Keynes through the use of the multiplier. A change in the level of investment determines a more than proportional change in the level of output. There will be only one level of investment for which aggregate demand is equal to aggregate supply.

This equilibrium level of income cannot be larger than that associated with full employment, but there is no reason

why it should be equal to it. In other words, the economy can find an equilibrium characterized by the existence of unemployment. Unemployment results every time firms as a whole invest less than it is necessary to justify the employment of all those who wish to work at the current wage rate.

The two crucial factors that determine investment – the marginal efficiency of capital and the rate of interest – are both essentially affected by the fundamentally uncertain environment in which the economy works. For Keynes, the uncertainty of the economic and social system cannot be dealt with by using the traditional tools of the theory of probability.

In this context, according to Keynes, present decisions concerning the future are based on conventions based on 'flimsy' foundations and, hence, subject to 'sudden and violent changes'. Thus, investment – a decision made in the present and concerning events to take place in a relatively distant future – gives rise to fluctuations in the aggregate levels of output and employment. The rate of interest depends on the supply of and the demand for money. In Keynes's world, money is not simply demanded as a means of circulation but also as a store of value. To demand money as a store of value is a form of defence against the uncertain future when people come to distrust the conventions on which they rely to make decisions. Thus, with a given quantity of money, the higher the desire to hold money the higher the rate of interest and, hence, the lower the level of investment.

Within this context, according to Keynes, it was very likely that the entrepreneurs' propensity to invest and the public's preference for liquidity worked to keep the economy in a state of chronic unemployment. This was a radical break with the past. As a direct consequence of Keynes's departure from the then prevailing paradigm, came the conviction that the economy could be brought to full employment only through an external intervention in the form of government measures to raise the economy's propensity to spend. Keynes, however, did not contemplate the creation of some form of socialist economy. He repeatedly underlined his aversion to socialism and his desire to reform rather than revolutionize the existent system.

Around the same time, other economists representing other theoretical traditions obtained results somewhat similar to Keynes's. Of particular importance in this respect are the contributions of certain Swedes and of the Polish economist M. Kalecki. The Swedish school of economics developed from Wicksell, who had already determined a shift toward aggregate demand and supply and the effects of monetary changes on the real sector of the economy. The younger generation took up this aspect of Wicksell's theory and developed a new approach to economics characterized by its concern for the study of output as a whole and by the emphasis on the role of expectations in the economic process. In this respect, Myrdal's *Monetary Equilibrium* (published in Swedish in 1931 and in English in 1939) is particularly relevant.

Keynes's essential conclusion that the spontaneous working of the economy may well give rise to chronic unemployment was also reached independently, more or less in the same years, by M. Kalecki, who was influenced by Marxist economics rather than Marshallian theory. Kalecki showed that investment is the prime factor in the dynamics of the economy, and it may remain below the level that ensures full employment. Furthermore, Kalecki explicitly abandoned the assumption of perfect competition and carried out his analysis within an oligopolistic environment.

## THE ERA OF KEYNESIANISM

From the end of the Second World War to the early 1970s, Keynesian macroeconomics was the dominant paradigm in most universities and research centres of the Western world. In addition, the policies adopted by many European and North American governments were largely inspired by Keynesian macroeconomics. However, post-war macroeconomics did not directly reflect Keynes's original theory. Rather, it was a sort of compromise between a pre-Keynesian vision of the working of the economy at the micro level and the acknowledgment of the existence of aggregate unemployment, which could be reduced through 'Keynesian recipes' – a version of Keynesianism called neoclassical synthesis.

In 1937, Hicks had written an article with the intention of presenting Keynes's theory in a synthetic way and contrasting it with the classical doctrine.[6] The thrust of Hicks's interpretation was that Keynes's theory was not so general as it claimed to be but, rather, a particular case of the classical theory. Unemployment depended on special factors and, in particular, on the rigidity of money wages. Although Keynes regarded his theory as a general alternative to the classics and pointed out that unemployment did not depend on wage rigidity, he did not strongly oppose Hicks's version of his theory and, in a few years, the latter became the standard representation of Keynes's macroeconomics under the name of IS-LM model.

IS-LM models are a sort of general equilibrium model in which the interdependency between the goods and the money sectors of the economy are analyzed. These models are largely used to study the effects of monetary and fiscal policies. Samuelson, Modigliani and Tobin have provided important contributions to the development of this version of Keynesianism. The application of Keynesianism to real economies required a vast and rather detailed empirical knowledge to implement and test effective fiscal and monetary policies. This also favoured the development of national accounting and the construction of large econometric models. The management of war economies had already given impetus to the development of modern national accounting with the pioneering work of Meade and Stone. The first large econometric models were mostly elaborated in the United States with the important contribution of L. Klein.[7] Already in the 1930s, J. Tinbergen had significantly contributed to the development of econometrics.

The neoclassical synthesis was affected by a number of theoretical weaknesses, among which its uneasiness to deal satisfactorily with inflation and the largely unexplained gap between the assumed optimizing behaviour of individuals and the non-optimal results achieved by the economy as a whole. These weaknesses became, in due time, the factors that have contributed to the demise of the neoclassical synthesis.

# UNEMPLOYMENT AND INFLATION

In the early 1970s, inflation became a very pressing world problem but dominant macroeconomics could not provide a satisfactory explanation for this phenomenon. Inflation was regarded as typical of economies in full employment, whereas the real world was affected simultaneously by high inflation and unemployment.

An attempt to give a more satisfactory explanation of inflation was based on the work of A. W. Phillips, who had established a functional relation between the rate of unemployment and the rate of growth of money wages. As unemployment decreases, the money wage rate tends to rise, but it remains stable only at a certain rate of unemployment. The neoclassical synthesis used Phillips's results to explain inflation by establishing a direct relation between the rise in money wages and the rise in the general price level (even though wages were assumed to grow more slowly) so that more employment was associated with lower real wages.

In the scenario based on the Phillips curve, workers are constantly 'cheated'. Higher money wages are only an 'illusion' because the higher inflation makes real wage rate fall. Friedman objected that, in reality, workers care for their real rather than the money wage rate and, therefore, in bargaining they take account of inflation, though imperfectly.

Friedman's alternative scenario went as follows. Let us assume that, initially, inflation is zero at a certain rate of inflation and that the government increases aggregate demand through a monetary policy to reduce unemployment. As a consequence, firms set higher prices and are ready to pay higher money wages to hire the available work force. Because workers do not anticipate inflation correctly, they think that their real wage rate has risen; the supply of labour increases and employment increases. However, when workers realize that their real wage has actually decreased, they demand higher money wages and this makes both prices and unemployment increase. This process comes to an end when workers do not expect any inflation and, hence, do not demand higher wages. There is only one point at which zero inflation can be rationally expected: the point associated with the initial rate of unemployment. Thus, in the long period, despite the government's attempts, the economy returns to this rate of unemployment that Friedman called 'natural rate of unemployment'. The economy, however, now experiences a higher rate of inflation.

The policy implications of Friedman's analysis were momentous: the government cannot permanently affect the behaviour of the economy by modifying the level of unemployment. The government can reduce unemployment only temporarily during the period in which workers learn to fully anticipate inflation.

# FROM MONETARISM TO NEW CLASSICAL MACROECONOMICS

Friedman's criticism of the Phillips curve and the explanation of inflation were part of a more general critique of Keynesianism, which he had been developing since the 1950s.[8] Friedman is the best-known representative of modern monetarism. Drawing on the pre-Keynesian quantity theory of money, contemporary monetarists, while criticizing Keynesians for having paid little attention to money, have argued in favour of the neutrality of money: in the long term, changes in the quantity of money affect only the general price level. The monetarist interpretation of the Phillips curve is an illustration of such neutrality. This approach has been also applied to the theory of the balance of payments and the determination of exchange rates. Both the balance of payments and the exchange rates are interpreted as monetary phenomena explained by the demand for and the supply of money.

Monetarism marked a return to pre-Keynesian economics, a process which has been fully accomplished by the so-called new classical macroeconomics, whose major representatives are R. E. Lucas Jr. and T. Sargent. New classical macroeconomists are all characterized by their adoption of the hypothesis of rational expectations, initially introduced by J. Muth in microeconomics, according to which agents behave in a fully rational way and, in forming their expectations, correctly use all available information. This hypothesis underlies the new classical critique of the Phillips curve.

In the monetarist interpretation, workers, though taking inflation into account, do not anticipate it correctly, which explains why expansionary monetary policies have positive temporary effects on unemployment. For new classical macroeconomics, workers anticipate inflation correctly, so that the economy immediately reaches a higher level of inflation with unemployment remaining at its natural rate. The new classical policy implications are even stronger than the monetarist: government interventions cannot even temporarily alter real variables and, therefore, they are negative or useless.

The neoclassical synthesis put together Keynesian macroeconomics and the marginalist approach to microeconomics. Thus, at the micro level, agents were postulated to be rational and optimizing, and markets were to operate in a way that ensured equilibrium through changes in prices. But, if individuals act rationally and optimize their objectives, how is it possible that the system does not achieve optimal results as well? This difficulty was partly overcome by introducing obstacles that prevented the economy as a whole from realizing optimal results. Wage rigidities were regarded as the factor that caused unemployment; if wages were flexible, the labour market would always be in equilibrium with unemployment. New classical macroeconomics refused any hypothesis of rigidity and assumed that all markets are continuously in equilibrium. Deviations of the economy from its 'natural position' can only derive from random shocks, which, in turn, are caused by changes in policy that agents may fail to anticipate immediately because taken by surprise. Along these lines, an 'equilibrium business cycle theory' has been developed.[9]

New classical macroeconomics has also exerted a strong influence on econometrics with its critique of Keynesian econometric models. Lucas pointed out that those models could not provide good forecasts of the effects of policy because of their inability to take account of how agents modify their behaviour in consequence of the policy measures themselves.

Recently, a group of economists, usually called new Keynesians, have criticized new classical macroeconomics for the unrealism of some of their assumptions and policy indications. New Keynesians argue that actual economies

are in fact affected by problems such as persistent unemployment, which cannot be explained and cured by new classical macroeconomics. New Keynesians take the new classical analytical framework as their starting point and try to obtain 'Keynesian results' by introducing additional hypotheses into that context. Such hypotheses involve market imperfections and imperfect knowledge and information. In contrast with the adherents of neoclassical synthesis, new Keynesians try to explain these imperfections through microeconomic analysis. Many new Keynesians have focused their attention on the working of the labour market in searching for an explanation for the rigidity of wages; others have concentrated on financial markets characterized by imperfect information.[10]

## GENERAL ECONOMIC EQUILIBRIUM AND THE FORMALIZATION OF ECONOMICS

Walras had published his most important work, *Elements of Pure Economics*, in the 1870s, but his approach to economics, based on the idea of general economic equilibrium, did not gain a wide acceptance at that time. It was not until the 1930s, that significant advances towards the modern formalization of the model of general equilibrium were made in continental Europe.[11] After the First World War, this approach was revived. Arrow and Debreu provided a rigorous demonstration of the existence of a general equilibrium position for an economy in which agents operate in perfectly competitive markets. Others, such as Hicks and Samuelson, concentrated on the problem of the stability of general equilibrium. Another important contribution in the field of general equilibrium economics was made by Arrow and Hahn.

A refined version of the general equilibrium approach has become standard and almost universally accepted by the profession. The highly formalized nature of this approach has naturally led to a growing use of mathematics in economics. But the progressive formalization is not a phenomenon confined to the study of general equilibrium. All fields of economic research have experienced an increasing use of advanced mathematical techniques. Although the advent and dominance of marginalism had already marked a significant increase in the degree of formalization of economics with respect to classical political economy, it was after the Second World War that formalization gained momentum in economics.

## ALTERNATIVE SCHOOLS OF ECONOMICS

The neoclassical synthesis, monetarism and new classical macroeconomics have largely dominated economics at different periods but not without opposition. A number of economists, known as post-Keynesians, have strongly opposed mainstream economics and proposed an alternative approach more closely related to Keynes's own ideas and, sometimes, to Kalecki's work. Among the founders of the post-Keynesian school were some economists closest to Keynes, such as J. Robinson, R. Kahn, N. Kaldor. The emphasis on the inherent instability of the economy and its tendency towards chronic unemployment are essential

characteristics of this school of thought. Other outstanding figures among the post-Keynesians are Weintraub, Minsky, Davidson, Pasinetti and Harcourt.

Since the 1960s, some post-Keynesians have joined forces with another group of economists, led by Sraffa, in their critique of the dominant paradigm. Sraffa's research concentrated on two connected fields of research: the critical edition (with Dobb) of Ricardo's works and his own book entitled *Production of Commodities by Means of Commodities* (1960). In his book, Sraffa solved some problems of the theory of value of classical political economy and offered an alternative to marginalism based on an approach focusing on the conditions under which the economy is able to give rise to a process of reproduction and growth rather than on individuals' choices in the allocation of scarce resources. Inspired by Sraffa, Robinson, Pasinetti, Garegnani, Harcourt and others criticized the marginalist theory of distribution based on the use of aggregate production functions and, in particular, the notion of aggregate capital, which was regarded as a logically flawed concept. The critique provoked a wide debate with Samuelson and Solow, the main defenders of the marginalist camp.

Among the other non-orthodox schools in economics, the two oldest are institutionalist and Marxist economics. Founded by T. Veblen, W. Mitchell and R. Common, institutionalism is characterized by its more empirical and historical approach to economics and by the important role played by institutions in the economic process. Modern institutionalism, while maintaining its focus on the role of institutions, also adopts a more formalized and analytical approach. R. Coase, J. Galbraith and G. Myrdal are generally regarded as institutionalist economists. While developing Marx's critique of capitalism, modern Marxist economics has largely concentrated on the problems of the Third World, which we consider in the next section.

## GROWTH AND DEVELOPMENT

Classical political economics of the nineteenth century had been mainly concerned with the problems of accumulation and economic growth. Marginalist economics, with its insistence on the notion of scarcity, paid very little attention to growth. The most significant exception was J. Schumpeter, who, in this respect, was closer to classical thinking and Marx. In Schumpeter's view,[12] capitalist economies undergo a process of cyclical growth driven by innovative entrepreneurs who introduce new methods of production in view of higher profits.

Schumpeter did not acquire a dominant position in the profession. A new interest in growth pioneered by R. F. Harrod followed the Keynesian revolution. By using some basic elements of Keynesian theory, he studied the conditions for a balanced process of growth and showed the extreme instability of such a process: if the economy deviates from its equilibrium path, there are no re-equilibrating forces at work. Domar achieved similar results working independently of Harrod. Other important contributions to the modern theory of growth came from Robinson, Kaldor and Solow.

Harrod was not concerned with income distribution; Kaldor introduced this topic in a model of growth[13] and started a wide debate on the relationship between growth and distribution, which brought in the debate on capital

theory. Pasinetti improved Kaldor's contribution and analyzed the functional relation between aggregate investment and profits.

Post-Keynesian models of economic growth, with some exceptions[14] are generally aggregate models. In the post-war period, by drawing on Leontief's analysis of inter-industrial flows of goods and services[15] and on von Neumann's model of general equilibrium many multi-sectoral models of economic growth have been built. In their 1964 publication, *The Theory of Economic Growth*, Hahn and Matthews provide a useful survey of the literature on economic growth up to the early 1960s.

In more recent years, the problem of growth has been mainly treated by the use of the so-called models of endogenous growth. In this approach, many important factors promoting economic growth, such as technical progress and education, are considered to be dependent upon the rate of growth – an old idea found in the works of Smith and, more recently, Kaldor. In addition, Romer and Lucas have presented well-known models of endogenous growth.

The concern for growth in the post-war period was also revived by the practical problems raised by the economies of many of the newly independent countries. For these countries at an early stage of development, the theories and policies developed in the more industrialized Western countries did not prove to be viable and immediately adaptable to their needs. Thus the autonomous branch of development economics emerged with the aim of providing an original approach to the problems of countries starting their process of growth almost two centuries after the Industrial Revolution in Europe.

In the early phase, the prevailing conviction was that developing countries could not possibly start a process of growth without significant external interventions and state and foreign aid. The state should provide the incentives for investment and production that the domestic and international markets could not produce spontaneously. In less-developed economies, growth was not hindered by labour scarcities; more serious obstacles were the scarcity of capital and aid from developed countries. State intervention was generally seen as aiming to engender a process of balanced growth, which could effectively exploit all the benefits of inter-industrial complementarities. An exception was Hirschman's position, which advocated unbalanced growth by favouring the more dynamic sectors of the economy, which, in turn, would promote and drive a more general process of development.

The persistence and, sometimes, the widening of the gap between developed and less-developed countries also produced rather pessimistic views about development. One of the factors, which, for many, prevented or delayed development, was the existence of unfavourable terms of trade between industrialized and developing countries. Structural differences produce a tendency for the prices of manufactured goods to remain higher than the prices of agricultural goods, so that developing countries' indispensable imports for growth are increasingly more expensive. But the existence of structural differences has not been invoked to explain terms of trade only. Several economists have elaborated analyses that explain the lack of development by the existence of a number of inflexible structural features affecting less-developed economies.[16]

Marxist and radical economists have paid much attention to developing countries. A basic feature of the Marxist approach has been the idea that the lack of development is a consequence of development itself. Industrial capitalist countries derive, to a large extent, their richness from the exploitation of poorer countries through international trade or from the availability of low-paid labour.[17]

In recent years, development economics has tended to be re-absorbed into economics in general, so that development is treated with the standard tools of the discipline, and the solution for the problems of less-developed countries are seen exclusively as policy problems. Unlike earlier economists, most specialists today advocate a declining role for the state and more reliability on the virtues of free markets. Largely as a reaction to these tendencies, others concerned with development have reacted by claiming that economics on its own is insufficient to cope with the problem of development, which requires a much wider perspective taking account of historical, social and cultural aspects.

## LEGAL SCIENCES

*Nicola Lacey*

At the end of the twentieth century, any review of the development of the legal sciences had to confront a number of challenges. Some of the most influential debates in social theory that have developed during the latter part of the century have questioned the very idea of law as a 'science': that is, as a discipline generating objectively validated knowledge or truth. More specifically, legal sciences are distinguished from most of the other disciplines addressed in this chapter by their connection with a distinct set of professional institutions and practices. Indeed, this connection and its consequences for the status of law as a discipline are unique among the ten disciplines explored in this chapter.

In considering the development of legal sciences, one is therefore confronted with at least two conceptions: the development of the legal sciences or legal theory; and practical 'legal science' a subject of study under the intellectual disciplines of law and legal pedagogy. In this review, we shall concentrate on the development of legal scholarship during the twentieth century, but any such enterprise must also deal with the relationship between developments in legal science and the fields of legal education and legal practice.

At the beginning of the twentieth century, law was already well established as a discipline in universities in most parts of the world. The academic institutionalization of law reflected the distinctive importance of law as a tool of governance in modern societies. Of course, the specific articulation of the relationship between law and the nation state varied enormously throughout the world. In the more secular Western societies, law was regarded as relatively separate from politics, playing a special role in negotiating the relationship between citizen and polity. In more traditional societies, the relationship between law and religious and political institutions is more intimate, and in the emerging socialist world, law is regarded as an explicit tool of state ideology. The modern Western ideal of the rule of law, and its associated conception of the separation of legislative, executive, and judicial powers had an enormous global significance as it was exported via colonization and incorporated into the emerging international legal order represented by the League of Nations and, subsequently,

the United Nations. During the first half of the twentieth century, the pre-eminent position of modern, relatively autonomous systems of law created the context within which the intellectual study of law would flourish and expand across the globe.

It should be noted that the world of legal scholarship, and hence the intellectual field of legal science, has never been confined to law schools. The study of rhetoric, theology, history and philosophy, for example, has always been associated with the study of law. With the development of the social sciences in the early part of the twentieth century, law also became a field of study within the newer disciplines of sociology, anthropology, political science and political economy. During the twentieth century, this link between law and the latter disciplines has brought about a re-evaluation of the study of law. No longer considered one of the humanities, law was regarded either as sub-discipline of social sciences or as a distinct field in its own right (this latter view being advocated by legal professionals). However, the appropriation of law by the social sciences has hardly been complete, and at the end of the century there were signs of a revival of the conception of law as belonging to the humanities. This recent tendency results in part from the injection of various European philosophical traditions within debates on the nature of law.

The general tendency in the twentieth century towards fragmentation and a blurring of the boundaries between the disciplines found particularly fertile ground in the legal establishment. In legal theory, as we shall see, this disciplinary context has generated successive attempts to delineate and conceptualize the specificity of legal reasoning and legal institutions. During the twentieth century, the uneasy relationship between the academic study of law and vocational legal training both supported and threatened the emergence of law as an autonomous intellectual discipline. The status of law as a distinct discipline has been rendered even more problematic by institutional changes in the forms, variety and location of legal practices. Legal sciences' greatest claims to specificity derive from the practical existence of laws: legal sciences are concerned with the study of a specific set of social practices. During the twentieth century, the fragility of law's status at the disciplinary level was

accompanied by significant changes at the institutional level, which have fragmented the practice of law and have generated numerous institutional changes.

At the practical level, the growth of state functions and the expanding sphere of legal regulation in the industrial and post-industrial countries blurred the distinctions between public and private spheres but also between legal and political governance. As law developed as a primary tool for the realization of government policy, the distinction between policy and law began to blur, thus raising crucial questions about the integrity of legal interpretation and the independence of the judicial function. At the same time, the diversification of legal regulation took law well beyond its traditional institutional framework, generating myriad new institutions with a mixture of juridical, administrative and therapeutic functions.

This expansion and diversification of the legal realm within the nation state was matched by the proliferation of non-state legal orders, which, with the increasing influence of sociology and anthropology on legal theory, finally began to claim the attention of legal science. The early impetus for this attention was probably provided by debate surrounding the relationship between indigenous and imperial legal systems in colonized countries. But the insights generated by scholars in developing countries, accelerated by the growing fields of anthropology and the sociology of law, have been increasingly prominent in the advanced economies. This has generated a vision of multiple, co-existing legal systems within and across the boundaries of particular territories, complicating the strong modern association of law with the nation state, and posing, in new wording, old questions about the relationship between law and other normative systems such as ethics, politics and religion. Moreover, the development of a variety of technologies – electronic communications, air travel – as well as the internationalization of markets, during the course of the century, has generated new legal phenomena, which are no longer compatible with traditional ideas of law as exclusively the product of the nation state. International and transnational legal orders are gradually developing with a variety of institutional frameworks more or less closely articulated with nation states. Not only the system of public international law but also regional structures such as the European Union and private frameworks such as the commercial *lex mercatoria* are posing new questions, which legal sciences are struggling to accommodate.

Four main theoretical approaches to law – each of which generates a different conception of legal science and a distinctive approach to the foundation of legal authority – emerged during the course of the twentieth century. The first is the doctrine of *legal positivism*. Positivism conceptualizes law as the product of human decision: as a distinctively institutionalized system of power, whose content is entirely determined by the legislative acts of political authorities. This engenders an essentially formal approach to the validity of laws: the validity and hence existence of any law is to be understood in terms of its pedigree and mode of enactment. In the Western world, legal positivism was undoubtedly the pre-eminent way of understanding law at the turn of the twentieth century, and this understanding is intimately related to the modern conception of legal science. The legal scientist is in command of the technical skills required for the identification and analysis of laws and is not concerned with the ethical or

political analysis of those laws but rather with the exercise of legal rationality. The positivist tradition engenders a primary focus on dogmatic and doctrinal analysis: on the complete, accurate ('scientific') and systematic description of the contents of particular legal orders; on scientific knowledge of particular legal systems and areas of legal regulation such as commercial law, the law of contracts and criminal law. The notion of autonomous legal science and its accompanying academic institutions therefore find their most perfect expression in the concept of positivism.

In spite of its pre-eminence in the Western world in the early twentieth century, the positivist conception of law and legal science has had by no means been the only approach. In particular, the continuing importance of the ancient tradition of *natural law* cannot be discounted. This naturalist tradition, and its numerous variants, views the sources of law's authority and validity as lying within extra-legal norms that derive from ethical or religious doctrines. During the eighteenth and nineteenth centuries, the increasing secularization of nation states led to a decline of the naturalist tradition in the Western world. Yet it may be argued that the modern conception of human rights, institutionalized across the globe in diverse national and international declarations and charters, constitutes a distinctive expression of the naturalist sentiment. Furthermore, even within secular polities, the latter part of the twentieth century witnessed an important revival of natural law thinking. This may have been in part a response to a crisis in the authority and perceived legitimacy of nation states and in particular to the abuse of state law by totalitarian regimes such as that of the National Socialist government in Germany in the 1930s and 1940s. It was vividly expressed, for example, in the concept of crimes against humanity retrospectively applied at the Nuremberg War Crimes Tribunal after the Second World War (Plate 101). On an intellectual level, the revival of the concept of natural law is related to the difficulties encountered by legal positivism in providing adequate justification for the foundations of legal authority. If, as positivism implies, law is simply the institutionalization of power, how can the authority of law and its claim to its subjects' allegiance and obedience be explained? The central problem, therefore, involves the very autonomy of the positivist conceptions of law: if law's authority and, hence, validity, can only be understood in terms of its relation to extra-legal norms, how can the continuing relevance and influence of those extra-legal standards (i.e. ethical or religious) be excluded from the interpretation and administration of law and from the study of these practices? It follows that the naturalist tradition advocates a broader conception of the realm of legal sciences than the positivist tradition, which focuses not only on the intricacies of legal doctrine and legal reasoning but also on the underlying principles informing and legitimating particular areas of law. The naturalist tradition regards legal science as markedly less distinct from the disciplines of ethics and political theory than does its positivist counterpart.

For proponents of natural law, there is no clear division between valid law and extra-legal norms: law is identified in terms of its compatibility with ethical standards, and there is no clear distinction between what law is and what law ought to be. While the term 'natural law' is associated with a tradition reaching back to Aristotle and developed by Catholic theologians such as St Thomas Aquinas, the broad

framework of natural law thought can encompass any system of legal science in which the question of legal validity is inextricable from questions of ethical, religious or other authority. Consequently, Islamic systems, now in place in many regions of the world, and which view legal, political and religious authority as intertwined, may be regarded as expressing a version of the naturalist approach. In such systems, the idea of law as an independent science is evidently less prevalent than in Western societies. Furthermore, in state socialist societies, the explicit realization of a particular ideology in legal terms might also be seen in terms of a natural law approach. Even in liberal democracies, the continuing power of the appeal to the role of law in upholding democracy and human rights might also be seen as consistent with the natural law tradition. Indeed, one of the central claims of critical legal theory (see below) has been that the positivist outlook is itself ideological, in that it conceals the problematic foundations of legal authority by representing political decisions as scientific truths, and by subtly representing the political dominance of a particular conception of law as the result of a historical process of evolution towards an ideal type.

The positivist conception of autonomous, technical legal science has always had to contend with powerful criticism from the naturalist tradition. In the twentieth century, however, it was also challenged by the phenomenal development of the social sciences, and hence with a third conception of *legal science as a social science*. In some senses the positivist conception of legal science has been a victim of its own success. As law's role as the pre-eminent tool of governance expanded with the broadening functions of the nation state, law itself was subject to the increasing influence of both politics and economics. If law was being used as a means to implement policy and economic regulation, law as a discipline appeared to be increasingly formal, a void to be filled by the imperatives of economic and political power. In several Western societies, the predominant pedagogic practices of conceptual and doctrinal analysis began to be challenged by sociological approaches. Instead of accepting legal forms and institutions as a given, sociological techniques were used to approach law as a social practice to be analysed in extra-legal scientific terms. Questions began to be asked about law's social, economic and political functions, the institutional, cultural and economic conditions of its existence, its varying forms and the significance of these variations, and the patterns of law creation, interpretation and enforcement through a variety of agencies extending well beyond the orthodox terrain of legislatures and courts. With the birth of the sociology of law came an increased emphasis on comparative legal studies, in which legal systems became the subject of comparative political, sociological and cultural analysis in much the same way political systems had been studied within the field of political science. In addition, a noteworthy 'realist' movement in legal theory developed. This movement was distinguished by its scepticism towards the substantive significance of legal doctrines and by the fact that it focused not on law's articulated standards but rather on its concrete effects and their underlying political causes.

In various fields, there was a prevailing tendency to reduce the specificity of law and legal rationality and to claim that legal phenomena and reasoning could be explained scientifically in terms of the tools used by social scientists. Perhaps not surprisingly, such ideas were relatively slow to infuse mainstream legal education and the legal establishment. Indeed, they attained a status roughly equal to that of doctrinal analysis only in a few parts of the world – notably North America – and only late in the century. This situation can be explained by the tension within the legal establishment between legal science as the study of legal phenomena and as practical knowledge with which law students should be inculcated. It is important to note that sociological approaches to law have also grappled with the question of the specific nature and autonomy of law. This fact is perhaps best exemplified by the idea of law as an 'autopoetic' or self-referential sub-system in a social world composed of many such systems – an approach that became influential in European legal theory in the late twentieth century.

Towards the end of the century, the manner of confronting legal science was further fragmented by the development of a fourth, heterogeneous family of approaches to legal theory. These *'critical' approaches* blend insights from the humanities and the social sciences. Examples include the development of feminist legal theories, critical race theories, post-colonial theories of law, and psychoanalytic and deconstructionist critical legal theory. As in the social sciences, these approaches – which derive in part from the development of new social movements such as feminist and anti-racist movements, but which also have important roots in Marxist and socialist thought – analyse law in terms of standards and influences outside law. They deal not only with legal rules, doctrines and institutions but also with the specific effects of institutions and laws. However, they differ significantly from standard social scientific approaches such as the sociology of law. To begin with, as they are more inclined to take the rational nature of law seriously, they tend to focus on the intricacies of legal doctrine, while exploring what doctrinal frameworks may systematically conceal, as well as the historical context of particular doctrinal frameworks. Secondly, they participate in an emerging scepticism about the very idea of objective scientific knowledge, emphasizing instead the way in which theories of law, and legal arguments themselves, are constructed from particular points of view.

To a greater extent than in the social sciences, these critical approaches have joined forces with humanistic practices such as analysing law as discourse or rhetoric, and raising epistemological questions about the basis for assertions of legal knowledge or truth. Like the social science approaches to law, however, these critical approaches have been relatively slow to find a broad foothold in the legal establishment. Once again, the explanation has to do with the tension between that establishment as an intellectual space open to ideas, which question its own status, and as a social institution whose existence is premised on the development of a specific discipline.

Each of these four families of legal science finds expression in many parts of the world today. At the dawn of the twenty-first century, it is impossible to identify a dominant conception of the legal sciences. Rather, we see a field which, notwithstanding its particularities, is characterized by both the globalizing influences and the gradual erosion of disciplinary boundaries, which has also affected other branches of social sciences.

Today, as at the outset of the twentieth century, law is one of the most important of the sciences of governance. In its future development, the tension between the imperatives

of the reproduction of professional legal castes and the increasingly interdisciplinary tendencies in the humanities and social sciences will undoubtedly create an increasingly fragmented, yet vibrant, discipline whose hybrid nature is unlikely to substantially undermine its institutional power.

## POLITICAL SCIENCE

*Björn Wittrock*

## INTRODUCTION: POLITICAL SCIENCE IN HISTORICAL PERSPECTIVE

Perhaps more than any other social science discipline, political science involves the study of problems that may appear to be timeless. Political thinking and philosophy are not limited to concerns of the contemporary era or of the last two hundred years; rather, they tend to deal with – or so we are led to believe – basic concerns inherent in any community forced to face major decisions regarding the means to attain the common good, the rulers to be chosen and the type of rule to be exercised. It is therefore easy to understand why proponents of the discipline so often invoke an Aristotelian notion of a science of politics as 'a master-science'.

The social science disciplines, as we know them today, were institutionalized in the late nineteenth and early twentieth centuries and shaped by the political, intellectual and institutional contexts. The new social sciences were forms of reflection on the broad societal processes of modernization and differentiation of working and everyday life that fundamentally transformed nineteenth-century societies in Europe and North America from rural, agrarian and localized into increasingly industrial, urban and nation state centred. These transformations, the coming of 'modernity', deeply affected discourses not only on 'the social question', i.e. the accommodation of the more or less uprooted masses of modern industrial society, but also on the creation of cultural and national identity and on the modern nation state that were to serve as vehicles for these processes.

The intellectual projects drafted to foster a better understanding of the role of state and politics in this new societal constellation varied greatly across nations. Sometimes they took the form of intellectual inquiry into those processes of state- and institution-building that were such a prominent part of the nineteenth-century societal strivings and beliefs. In some cases – as in the analyses by Andrews, Furner, Haskell, Ross, Silva and Slaughter, or Manicas – the professionalization of political scientists is seen as an effort among former elites to prepare for reforms designed to preserve the traditional aspects of the discipline

from the onslaught of modernity. In other cases, the emergence of young nation states meant that the constitution of a new political, administrative and legal order was an urgent item on the public agenda and some form of 'state sciences' was expected to provide some of the answers.

## EVOLUTION AND CONSOLIDATION OF POLITICAL SCIENCE: FOUR TRADITIONS

The different developmental paths of political science throughout history may be understood in terms of four broad intellectual traditions that came to influence the discipline differently across countries and regions.

First, a realm of *historical-philosophical* discourse on politics existed in eighteenth-century Europe and also included discourses on political economy. This historical-philosophical discursive field was clearly the cradle of a discipline of politics in Britain and in a number of its former colonies. A series of scholars have argued that the notion of a science of politics emerged out of the concerns to constrain undue enthusiasm and passion. The key proponents of this new science were moral philosophers and political economists, including thinkers of the late-eighteenth century Scottish Enlightenment.

Hume, Smith, Ferguson, Millar and Stewart all contributed to the outline of an inquiry into constitutions and political institutions conducive to restraint and moderation in governance. Such a mode of inquiry was designed to go beyond the merely descriptively historical and to link historical examples to a scientific understanding of human nature and of the propitious conditions for the emergence of free commerce, markets and trade.

This encompassing project of a historical and moral philosophical discourse on politics and governance may be seen as a continuation of the broad intellectual tradition of the so-called moral sciences. In British discourse on the study of politics, it may even be considered a root metaphor for such discourse. In this perspective, perhaps the 'tragedy of political science' – to borrow Ricci's term – is that it has divested itself of a serious concern for moral argument and

its potential to shed light on crucial issues in order to preserve wisdom and prudence in government. However, the concern for normative theory as well as for institutional and intellectual history that was central to this tradition does not seem to have been weakened but rather 'to have strengthened its influence over time'.[1] Nevertheless, a slow process of professional and technical specialization came to define standards of technical competence that gradually seemed to impede dialogue between the representatives of these disciplines and academics lecturing and studying in the field of politics. However, the renaissance in recent decades, propelled by scholars representing different branches of political science such as intellectual history and normative political philosophy, now makes these fears seem exaggerated. In fact, the broad historical-philosophical tradition, sometimes suspected to be superseded by the achievements of the so-called behavioural revolution of the 1950s and 1960s, now stands out as more vital and important to the future of the discipline than ever before. It is also noticeable that in recent years, the openness within the discipline of political science and outside of it has increased dramatically.

However, 'the tragedy of political science' has another side to it, namely the departure of other discourses from the general realm which had once been shared by students of politics, history, moral philosophy, and political economy. From this perspective, the study of politics is not so much a new discipline of political 'science' but rather something of a secondary discipline, i.e. that which remains of a once-encompassing undertaking after other modes of systematic inquiry have branched off and established themselves as well-entrenched and essentially self-contained modes of analysis.

*Political economy* was the first specialized type of discourse within this broad constellation to distinguish itself intellectually in disciplinary terms. Already in the early nineteenth century, political economy constituted a clearly delimited domain of discourse of its own, although it maintained strong links to history throughout that century. Only much later did corresponding shifts towards technical specialization seriously erode the feasibility of history and philosophy serving as 'the twin pillars' – to use David Held's term – of an academic discourse on politics. Nevertheless, there always existed a practice of reasoning on politics that draws on a tradition of *rationalistic-deductive theorizing*. The renewed dialogue between contemporary economics and rational choice theory, on the one hand, and political science at large, on the other, has often been able to draw on this tradition and to revive it significantly.

A third realm of discourse that deeply affected the emerging discipline of politics and government may be termed *legal-administrative*. The old tradition of the princely states, e.g. Germany, Austria, but also Russia and Scandinavia, of the late eighteenth and early nineteenth centuries to underpin administration and governance by way of an array of so-called police and cameral sciences could perhaps even be considered a precursor to modern policy sciences. It would, however, be a gross simplification to construe anything like a clear continuity in scholarly terms between these early endeavours and the increasing policy orientation in the modern social and political sciences. But in terms of administrative practices, state production of comprehensive statistics, as well as in the establishment of institutions for the training of administrative personnel, there are some lasting influences on the shaping of modern social science disciplines.

Administratively and legally oriented discourse on politics and the state in continental Europe of the late nineteenth century in the tradition of the 'sciences of the state' tended to evolve in an increasingly abstract and generalizing direction. It largely came to focus on the encompassing project of elaborating a coherent legal system that might serve both as a rationale and a guideline for the bureaucratic governance of the new or renewed nation states of Europe. This programme of so-called legal positivism became a central component of the modern version of state sciences, but it also served as a benchmark for critics who strove to expound a theory giving fuller weight to the actual practices and power struggles in interventionist states.

This type of legal-administrative discourse came to exert a powerful influence well beyond continental Europe. Thus it has been argued, particularly by Gunnell, that it also deeply affected early American political science and served as a link between inquiry into empirical and normative issues by way of a hypothesized entity representing an assumed societal consensus beyond the mere operations of a governmental apparatus or the strivings of diverse popular factions. A theory of the state became an intellectual means to fill in the missing link between the idealized entity 'We, the people' of the American Constitution and the bewildering multiplicity of diverse social, ethnic and religious factions making up the population of the vast new country. The legal-administrative tradition also proved critical to the development of political reasoning in Eastern Europe, Latin America and in several Asian countries.

Aside from the purely legally oriented discourse and statistical studies, there was another line of research and practice of major importance for the emerging discipline of political science: the efforts by entrepreneurial individuals to modernize and professionalize the training of administrators while linking it up to a scholarly programme of research. This was essentially the project of Emile Boutmy that led to the establishment of the École libres des sciences politiques in Paris and similar efforts were made, though with considerably less success, in other settings (e.g. in Italy) at roughly the same time. As often is the case with contemporary public administration and public policy schools, many of these efforts were marked by conflict between the demands inherent in the professional training programme and the demands of a scholarly-driven intellectual enterprise, and in such a struggle the latter component easily tends to lose the upper hand.

The school at Columbia, established in 1880 and modelled partly on Boutmy's school, was an exception in its emphasis on scholarship rather than on professional training, despite the fact that it developed under the intellectual leadership of German-trained scholars such as Burgess. In some ways, the whole broad and highly consequential development of schools of public policy and public administration and management draws on this older tradition of political science and constitutes a continuation of this tradition even though it was strongly influence by a more economic-rationalistic (micro-economic) type of reasoning.

In the continental European setting of the first half of the twentieth century, the tradition of the 'state sciences' remained legalistic in its orientation, and after the Second World War it was often perceived as a 'blind alley' by representatives of a more empiricist and behavioural form of political science. It is interesting to note, however, that three broad areas of research, which are crucial today,

advocate a renewal of a type of reasoning that had been of such importance to the older generation of scholars, namely those associated with the constitution of overarching political orders such as the European Union, with the establishment of constitutional foundations in new polities, whether in Eastern Europe or in the Third World, and with the analysis of the nature of international regimes and order. These new fields of research have witnessed a renewed interest in legal-constitutional reasoning, often in fruitful dialogue with rationalistic-deductive and historical-philosophical reasoning, and require once-prominent forms of competence that were neglected to some extent within the discipline of political science during part of the post-Second World War period.

A fourth major intellectual tradition known as the *sociological-behavioural* exerted the greatest influence on the evolution of political science in the twentieth century. Some of its roots may be traced back to the discourse on systematic and societal constraints that emerged in the wake of the French Revolution. However, whereas continental European thinking tended to be systemic and structural, in the American setting it became linked to pragmatist philosophy and an empiricist epistemology giving rise to a new form of behavioural social and political science. It is the breakthrough of this tradition in North America in the interwar period that set the stage for the subsequent so-called *behavioural revolution* in international political science in the decades following the Second World War.

The discipline's key transitional figure is Charles Merriam, who was entirely familiar with the early American tradition of state-centred political science – from Lieber, Burgess and Adams and Willoughby to his teacher Dunning – and also with European scholarship of the same period. In a remarkable way, Merriam represents continuity and innovation, disciplinary demarcation and interdisciplinarity. Merriam is generally heralded as the progenitor of modern empirically oriented political science, at least in the American context, but he is also an advocate of cross-disciplinary collaboration, as were many later behavioural social scientists.

Also facilitating the rapid development of political science in the United States was the fact that the linkage between the different realms of discourse presented above was established much earlier and more successfully than it was in Europe, even though many of the most significant developments within all these realms continued to occur in European universities. In Europe, however, few or no settings existed that could serve as a catalyst for new types of inquiry into political matters, involving research of a mainly behavioural nature, as occurred at the universities of Chicago or Columbia.

Already in 1924, Charles Merriam emphasized the relevance of the new development of behaviourally oriented social and political science and pointed out the importance of public opinion and voting behaviour, political parties and interest groups, and the possibility of an empirical study of these foundations and backgrounds to formally organized government. There were both intradisciplinary and political-societal reasons for the shift towards classificatory inductivism in the study of institutions. Thus it coincided with a strong aversion to strictly formalistic reasoning expounding the rationale of the state in terms of a legal positivistic discourse. The belated and, as it turned out, often ephemeral triumph of parliamentary democracy in

European nations in the wake of the First World War was sometimes perceived as a repudiation of abstract reasoning premised on the assumed existence of an interest and rationale of the state beyond the realm of critical reasoning.

Thus an intellectual rupture occurred in American political science in the interwar years. However, the later US careers of European or European-trained scholars such as Kelsen and Morgenthau bear witness to the fact that parts of the earlier traditions of legal discourse came to exert an indirect and sometimes inadvertent influence also on American political and social science in later decades, albeit an influence largely taken out of the intellectual context in which these modes of theorizing had been shaped.

## EXPANSION AND INTERNATIONALIZATION OF PROFESSIONAL POLITICAL SCIENCE

The modern discipline of political science is to a large extent a post-Second World War phenomenon that occurred both at the international and the national levels.[2] Along with the establishment of the International Political Science Association (IPSA) under the auspices of UNESCO in 1949, there began a gradual process whereby political science came to be introduced or fundamentally redefined in a diversity of national settings, including the Netherlands, Norway and West Germany but also in Latin America, Australia, India and Japan and several other Asian countries. These developments often meant that elements of the sociological-behavioural tradition came to affect research in political science but rarely to such an extent that other earlier traditions were totally marginalized. A process of professionalization was set in motion and came to exert a truly profound worldwide influence in the wake of the expansion of higher education systems in a many countries in the 1960s and early 1970s.

With the spectacular expansion of higher education systems and the parallel processes of administrative reform, political science became firmly entrenched as an academic discipline in the university systems. Moreover, in many countries the rise to power of new political majorities and the launching of major new public policy programmes across the board also fostered this evolution. In the age of great public policy programmes, political science was able to secure a firm basis in a series of European countries, either for the first time (e.g. Denmark) or in a renewed and greatly expanded form (e.g. Britain, Germany and Sweden). This expansion was accompanied by the emergence of the discipline on an international level, which endowed the International Political Science Association with a truly international character.

On all continents, the full array of sub-disciplines included institutional and behavioural studies devoted to a single country, comparative analysis, public administration and the related expanding fields of policy studies, local government, international relations, political sociology, constitutional history and law, political economy, and – no longer a core component but rather one of many specialties – political theory and philosophy.

This impressive expansion has been accompanied by enhanced research methods. Thus a previously predominant concern for political institutions and processes on a national level (principally in Latin America, Europe, Australia, Japan

and India rather than in the United States) was progressively enriched by a stronger research orientation towards international relations and organizations and towards local and regional level government. In terms of research methods, the 1960s were the breakthrough years of the pending behavioural revolution, which were partly the result of the efforts of European scholars in the interwar period. No longer could historical, juridical and philosophical reasoning, taken alone or collectively, be considered sufficient for the analysis of political phenomena. Methods and techniques previously elaborated in statistics, sociology, psychology, and economics were now being utilized by political scientists on a vast scale.

This shift in research methodology coincided with the expansion of the discipline. In Europe, it was often complemented by the introduction of a more formalized graduate programme generally with compulsory courses in research methodology. A recurrent stimulus was the European Consortium for Political Research, itself a product of the 1960s, which through its annual workshops, research groups and summer schools exerted a lasting influence on several generations of young European political scientists by creating an informal 'invisible college' of younger scholars. In those universities and countries where this shift was most actively pursued, there were certainly instances where pre-existing juridical, historical and philosophical competence was either partially lost or could not keep up with developments in related disciplines thus becoming gradually antiquated and out of touch with the initial rationale for the use of these traditional methods.

Apart from external political-societal reasons for the predominance of one particular mode of disciplinary identity, the defining factor of the early pre-war period was that the only country in which the political science structures had sufficient size and scope to make widespread international impact was the United States. In the early 1950s, the American disciplinary association had more than 5,000 members, whereas European membership averaged less than 1 per cent of that number. Today membership in America has tripled and the combined enrolment of European political science associations has yet to reach 5,000 members.

With the exception of Britain, France and possibly Germany and Sweden, the United States seemed to be the only country whose version of a science of politics clearly responded to the intellectual concerns of institutionally successful precursors of the late nineteenth and early twentieth centuries. As noted by Bernard Crick, at least from the time of the address by the then-president of the American Political Science Association, Charles Merriam, in 1923 to the address by Pendleton Herring thirty years later (and to the one delivered by Samuel Huntington another quarter of a century later), there has been a persistent notion that political science is intimately linked to the intellectual and institutional history of the United States and constitutes an American-conceived science that has successfully spread to a range of nations, whose effective, if belated, acceptance of a pluralistic political system has qualified them as proper recipients of this intellectual heritage.

However understandable such a perspective may be, it is based upon the misperception that political science is identified with a particular form of inquiry – related to liberal individualism – that played a predominant role within the first professional political science community, which has since become an international model. Nonetheless, from both a historical and contemporary perspective, this simple identification cannot be easily upheld. In fact, American political science may show signs of renewed dependence on theoretical discourse as it has evolved in other continents over the last decades of the twentieth century.

In the major sub-disciplines of political science, substantial differences in terms of emphasis and major foci continue to exist. Thus in political theory and philosophy, liberal individualism largely seems to serve as a tacit point of departure for much, if not most of, American political philosophy. No doubt these types of theorizing, as epitomized by rational choice theorizing, continue to exert an important influence in Asia, Africa, Latin America and Europe as well. However, other equally influential modes of political philosophy are prevalent. One major development has been the tendency to link previously separate fields of theoretical research, and particularly the linking of an institutional analysis of the conditions for preparing and implementing policies with a normatively oriented analysis of the implications of such policies for justice in society.

In all countries, most political science activities continue to focus on the actual workings of national political systems. Studies of legislatures, executives, political parties, interest groups and electoral behaviour tend, almost by necessity, to focus on the national context. This is most true of the purely institutional analysis. Thus, there has long existed a strong international and comparatively oriented research community in fields such as electoral behaviour and the study of the role of mass media in the political process. The seemingly secular erosion of traditional party identities and affiliations in Western Europe and the dramatic transformations occurring in Eastern Europe have also served as a powerful stimulus for comparatively oriented studies.

Much the same holds true in another sub-field of political science, namely the study of public administration and public policy. A strong and vital tradition in recent decades has pushed this type of research far beyond a concern for only the formal workings of a government administration or the comparative study of attitudes of bureaucrats and politicians, whether at the national, regional or local level. Instead current research increasingly focuses on the actual processes of policymaking and policy implementation. This type of research was often stimulated by the expansion of government activities and policies and by the perplexing failures of government programmes in terms of 'implementation deficits'. A large body of research has tried to examine to what extent and under what conditions political forces can affect not only government decisions but also actual policy outcomes. In an age of growing international interdependence, intractable long-term problems, such as the conditions of the human environment and the nature of economic policy, have stimulated interest in such research.

A significant development currently underway involves efforts to associate an analysis of the workings of public and private organizations with the study of the conditions for long-term institutional change.[3] Clearly, the slowly changing fundamental role of national governments and the emergence of a new confederate political entity, such as the European Union and its vast organizational structure, offers yet another major opportunity to analyse the development of political and administrative arrangements.

In the sub-field of international relations, subjects such as the East-West conflict, interaction between the developed and developing countries and the functioning of large-scale international organizations previously predominated. In

recent years, however, a range of new research efforts designed to come to terms with the rapidly changing international scene has emerged. This has occurred alongside interesting and fundamental restructuring within the study of international relations itself, including questioning analysis that takes a purely *realpolitik* approach more or less for granted. Thus, the study of international relations is currently engaged in a fascinating process of change.

## POLITICAL SCIENCE IN THE PRESENT AGE: DIALOGUE AND DIVERSITY

The present situation might be summed up succinctly by means of two observations. First, the advances in the development of research methodology and knowledge about the real world of politics in recent decades have been impressive. In many ways, the history of political science in the twentieth century must be seen in terms of developments before and after the broad professional breakthrough of the discipline in the 1950s and 1960s and the ways in which this breakthrough produced focal points concerning debates about texts that came to be regarded as 'modern classics' without the emergence of any single strict methodological canon.

In this respect, the 'post-behavioural' phase of disciplinary development from the 1970s to the present has been marked by the co-existence of a strong empirical and survey research tradition, of public policy analysis and systematic empirically oriented comparative politics and international relations research alongside a renewed interest in normative political philosophy, a rediscovery of institutions, including macro-historical studies of state institutions and state systems but also the introduction of various types of linguistic and rhetorical analysis. In this later period as well, however, we might ask whether the co-existence of different sub-disciplines prevents consensus over which works deserve to serve as focal points for intellectual debates.

Secondly, differences in research interests and style in political science persist and cannot realistically be expected to disappear. As previously pointed out, such differences must be understood against the background of the substantial differences in the role and conception of state and public activities in various parts of the world, not least between the United States and a number of European countries. These differences reflect the fact that the development of the social sciences must be analysed against the backdrop of intellectual traditions as well as institutional legacies and broad societal concerns.

It is important to recognize the foundational and reflexive nature of political inquiry. Political scientists should emphasize the dual nature of the discipline's history, on the one hand, grounded in issues centring on argumentation and power, talk and force, signification and domination and on the other hand, a relatively recent set of professional practices.

A roundtable of American political scientists in the early 1990s examining the nature of contemporary political science came to a similar conclusion as to the present state of the discipline. Thus one objective for an examination of the development of political science must be to account for the special nature of political science as a discipline. On the one hand, it is one modern social science discipline among others, and in this respect it has proven its mettle, even if its modern guise remains relatively new in some countries. On the other hand, it is largely and essentially clustered around a set of key concerns about the legitimacy of rulers and the making of the basic rules and societal institutions, i.e. the problems of constituting a political order. These concerns are not transient but recur with each successive generation. The foundational transformations of Eastern and Central Europe have once again forced these basic questions of political inquiry onto political and scholarly agendas.

It follows that a search for a solution to the most essential problems of politics and order must be an in-depth inquiry that draws on knowledge from diverse fields. Any truly innovative political inquiry has to be contextually sensitive and must rely on knowledge available in various social science and cultural science disciplines. This position is widely recognized by most observers. However, to account for this particular position of political science and inquiry, the analysis of the formation and development of the discipline in different national contexts must be pursued not as a pastime for the sake of recording recent achievements but as a major component of intellectual advancement.

## POLITICAL SCIENCE IN THE FUTURE

Political science has to a large extent emerged and evolved as a confederation of diverse practices held together by institutional consensus rather than by a common conception of a theoretical research programme and scholarly tradition. This may help safeguard a fair amount of intellectual pluralism and guarantee scholarly vitality and growth. However, it probably also leaves the field more open to societal and administrative influences and less able systematically to draw on theoretical advances in related intellectual fields. Just such an observation was a major premise of David Easton's classic study, *The Political System*. Easton's concerns are echoed in the words of David Held, a scholar of a later generation who argues for the need for a discipline that systematically confronts the abstract normative reasoning of political philosophy with a keen understanding of the actual constraints and potentials in terms of various social groups' power resources and of the processes of distributing such resources. These optimal conditions are more urgently needed when preferences are initially being formed rather than when these preferences are assessed in terms of costs and benefits of courses of action. This position is consistent with the type of broadly historical comparative study of politics and society envisaged in the writings of Weber and Durkheim, who sharply criticized the emerging discipline of political science for ignoring this point.

Nowadays, when social scientists once again have to question the very form of political organization upon which so much of their theorizing is premised, the archetypical nation state, and its presuppositions concerning amply available natural resources and increasingly efficient technology, Held's warning against complacency and disciplinary myopia should be interpreted as a scholarly challenge rather than a threat.

The fact that the basic political and societal macro-institutions that have been more or less taken for granted for at least a century and a half – i.e. the modern nation state, the modern large-scale corporation, the modern research-oriented university and modern science itself – are currently undergoing fundamental transformations should

make such scholarly flexibility seem not only natural but necessary. Clearly, a number of assumptions concerning our deepest cultural and national identities and their relationship to the basic forms of political and social organization have to be examined anew with the same readiness to undertake foundational inquiry as political philosophers and students have shown in earlier periods of fundamental change.

In this respect, the special nature of political science as a field within a relatively modern profession dealing with perennial questions about the nature of the political order and the legitimacy of ruling and power should be seen as an asset rather than a liability, but to do so, political scientists must first face up to their own history and its legacies. This is important not so much for the future of political science as a profession (the continuation of a lively confederation centred on professional concerns seems reasonably secured), but because an understanding of the position of modern humankind requires facing some very difficult questions concerning our identity and the manner in which our words and actions are linked to societal rules and resources. These are, indeed, the kind of questions with which the best kind of political inquiry has always been concerned, i.e. a political science with a focus on the problems of argumentation and domination, discourse, institutions and history, and with a great degree of openness towards other disciplines. Such scholarship will be crucial to the civilized community of humankind in the face of greater demands for institutional learning and environmental and human sensitivity in the future. Thus the prospects of such a political science are relevant far beyond the confines of the discipline itself.

## LINGUISTICS

*Stephen A. Wurm*

In the early twentieth century, the school of comparative-historical linguistics that had dominated the nineteenth century was increasingly overshadowed by structuralism and other theoretical approaches. Nevertheless, comparative-historical linguistic work continued to have a following among scholars studying less-known languages such as Austronesian (Dempwolff), South-East Asian (Benedict), Uralian (Rédei), Altaic (Poppe), African (Greenberg), and American Indian (Campbell and Mithun). In recent decades, the approach has delivered some spectacular results in these previously neglected areas. A striking example is the postulation of the huge Papuan Trans-New Guinea Phylum by McElhanon and Voorhoeve and Wurm, which comprises about 500 of the approximately 750 Papuan languages, and whose existence is now being documented. Comparative work by Foley in some Papuan language families should also be mentioned. Another outstanding recent example is the wide-ranging comparative-historical work by Ross in a large number of Austronesian languages in Melanesia in the south-west Pacific. Similar work is underway in some other parts of Australia, South-East Asia, and the Americas. At the same time, T. Gamkrelidse and V. V. Ivanov, two linguists from the Republic of Georgia, arrived at important new insights into the Indo-European language system. Also, a new trend in linguistics, paleolinguistics, appeared with the reconstruction of ancient phonetics and semantics, e.g. in the works of B. Kalgren, G. Malmquist, E. Pulleyblank, S. Egerod in Chinese; N. Marr in Caucasian languages; and J. Meshchaninov in Arctic languages.

Despite these important contributions, the main linguistic stream in early-twentieth-century Europe and America was a structuralist approach to language. The first proponent of this theoretical approach in Europe was the Swiss linguist Ferdinand de Saussure, whose contributions were published by Charles Bally and Albert Sechehaye in 1916, three years after his death. One of his lasting legacies to twentieth-century linguistics was the sharp distinction between the *synchronic* and *diachronic* approaches in linguistic study. Also very important for modern linguistics was his recognition of the opposition between the social and systematic side of language as an abstract model (called *langue* by him) and individual speech as concrete

manifestations (*parole*), and his claim that linguistics should be studied within the wider context of the study of sign systems in society, which he called 'semiology' and which later became known as *semiotics*. Another important view held by Saussure was that language is not a substance, but a form.

Saussure's ideas, and especially his concern with the abstract and systematic aspects of language, were challenged by Louis Hjelmslev, the most important member of the Linguistic Circle of Copenhagen, who developed the theory of *Glossematics*. He argued that linguistics could only describe relations, i.e. dependencies or functions between items, not the items themselves. One of the important features of glossematics was the study of content and form in trying to arrive at a structural investigation of semantics. *Componential analysis* has parallels to this and has influenced other schools of linguistics such as *stratificational grammar* and, in dealing with general semiotic concepts, has had an influence on semiotic theories.

Another leading school of linguistics in the mid-twentieth century was the Prague School. It was the first to recognize the function of the *phoneme* as the basic unit of phonology, whose sound properties distinguish words of unlike meaning in a language as defined by Roman Jakobson, a leading member of the Prague School. They recognized the presence of binary oppositions of phonemic pairs whose members differed in a single distinctive feature, calling the opposing members *marked* and *unmarked*. These concepts reappeared in other theoretical approaches in the latter part of the century. Binary phonemic oppositions were recognized as constituting the phonological system of a language. Adherents of the Prague School, or Praguians, tried to formulate general universally valid phonological rules and examined the degree to which phonemes were utilized in a specific language; their work proved useful for language teaching and was a precursor of later research in contrastive linguistics and language planning. The Praguians realized that the sound system was only one part of a language, with phonology and morphology being very close relations. Nicolai Trubetzkoy, one of their members, introduced the still valid concept of the *morpheme*. Linguistic diachrony also attracted the Praguians' interest, as did questions of

written language, which was viewed as being systemically independent from spoken language.

The London School was another major twentieth-century centre of linguistics research. Its founder and principal proponent was John Rupert Firth, who established linguistics as an academic discipline in British universities in the decade after the Second World War. Firth's main interests lay in *prosodic phonology*, which challenged existing phonological theories, and in semantic theory. Prosodic phonology did not intend to produce the simplest overall description of the phonology of a language but to give a clearer, more coherent account especially suitable for studying data in terms of a polysystemic statement. In this prosodic phonology, termed *prosodic analysis* by Firth, no one-to-one relationship between phonetic and phonological items is assumed. Rather, it presupposed an interdependence of phonology and grammar, thereby rendering any intermediary morphophonemic level unnecessary. The polysystemic approach allowed the setting up of separate phonological systems for grammatical structures, and for special phonological systems for loanwords. Another of Firth's interests was the study of linguistic meaning in terms of contextual semantics, called the theory of the *context of situation*. It was his belief that semantics was central to linguistics, a position that strongly contrasted with the views of many linguists of the day, especially in America. Firth took the view that every language was embedded in the culture of its speakers. This view also led him to pay special attention to what he called *restricted languages* with their own vocabulary and grammatical and even phonetic features, and used in specific contexts, such as professional technical language, rhetorical speeches, official correspondence and so on. Firth's linguistic views later became influential in Halliday's *Systemic Grammar*, which presented a comprehensive linguistic theory and analysis like the one Firth had intended to produce. Also, recent post-phonemic phonological approaches such as *autosegmental phonology* are close to Firth's views on phonology. This autosegmental phonology developed from research into generative phonology in the 1970s when some problems in that phonological theory became evident. Until then, the prevalent view held that speech was linear and consisted of a single sequence of phonemes separated by discrete boundaries. However, increasing evidence from descriptions of Asian and African tone languages indicated that speech sounds showed much overlap, with tonal features only loosely related to the segmental phonemes with which they were connected. This and similar problems in the analysis of complex segments convinced more and more linguists that the segmental view of phonology needed revision, thus leading to the development of autosegmental phonology.

A crucial chapter in the history of linguistics in the twentieth century is *American structural linguistics*. Its basic tenet, held by many linguists, was that the discrete elements of language formed structures and patterns. Great importance was attributed to spoken language, and intellectual ties between linguistics and anthropology were close. This current originated in to the late nineteenth century in connection with work in Native American languages. Anthropologist Franz Boas had observed that inconsistencies in the transcription of words from these languages made it possible to guess the nationality of the transcriber, which in turn made it possible to place into a cultural matrix structural views in language resulting from the observation of verbal interaction. Edward Sapir, one of

Boas' students, brought the descriptive model close to modern structuralism in his insights into the link between form and meaning. Leonard Bloomfield exercised very strong influence on American linguistics in the first decades of the twentieth century. He advocated that linguists should work without preconceptions and observe the forms of each language in order to establish their language-specific functions. He rejected the traditional belief of linguists that there were presumably some universal grammatical categories in every language. In their work, both Sapir and Bloomfield emphasized the distinctive sounds and forms in languages and meaningful distributional patterns. This focus on forms specific to each language was expanded after 1940 by other American linguists such as Bernard Bloch, Charles Hockett, Zellig Harris and George Trager, whose *distributionalism* largely avoided considerations of meaning in linguistic analysis and relied on a solely distributional analysis of a *corpus*, i.e. written linguistic data. Semantics was considered too vague, and synonymy – in terms of identity of distribution only – was regarded as non-existent. In their work, the contrastive and non-contrastive distribution of elements was central to analysis.

*Generative grammar* was introduced by Noam Chomsky (Plate 102) His theoretical approach was based on generative syntax and the rejection of structuralist linguistics, though Chomsky and his followers used distributionalist techniques in the tradition of American structuralism. Chomsky's theory has moved in a number of different directions since its inception, but they all share two main aims: to formally describe the universal features of grammars of individual languages and to describe the inherent knowledge, referred to as *competence*, which native speakers possess about syntactic, phonological, morphological, and semantic patterns in their language. Both generativists and structuralists believe that a grammar is a description of the structural relationships between elements in a given language. In fact, generative competence, and what is called *performance*, are modern reinterpretations of Saussure's *langue* and *parole*. One major difference between the generative and structuralist approach is found in the goal of linguistic theory. Structuralists established lists of linguistic elements of a language and indicated their distribution, whereas Chomsky's theory aimed at defining what kind of grammatical processes *can* occur in language in terms of a universal grammar which he regarded as an innate faculty of the human mind, brought into being by the child in the course of acquiring a language. Generativists adopted the view of Bloomfield's successors that syntax could not be derived from the study of meaning as the *autonomy of syntax*.

The Prague School also influenced generative thinking, especially in phonology, but also in the search for linguistic universals. Generative syntax has been influenced by Otto Jespersen's views, and generative grammar has been aided both by studies in mathematical logic from the 1940s and 1950s, and changes in the views of philosophers of science and developments in cognitive psychology. Chomsky's 1957 theory relied on *phrase structure rules* and *transformations*. The latter changed grammatical relations, and produced complex sentences from simple ones. In 1965 Chomsky presented the *standard theory* of generative syntax. In this, phrase structure rules made so-called embedding transformations superfluous, and introduced a separate lexicon. This made it possible to postulate a separate level of deep structure, which was also the seat of semantic interpretation, while transformational rules

imposed deep structures onto surface structures. After 1965, one new development in syntactic theory was *generative semantics*, which rejected the need for a separate deep structure level on the grounds that transformational rules already present imposed semantic notions directly on surface structures. It moved away from many of the conceptions of generative grammar, but eventually died out by the middle of the 1970s.

After 1965, an Extended Standard Theory (EST) developed, splitting into two theories following the demise of generative semantics, with both of them still pursued today. One of them, developed by Chomsky himself and called the Government Binding (GB) Theory, is characterized by the gradual replacement of language-specific rules by general universal principles of extreme abstractness and complexity of supporting arguments. The other has two branches, the Generalized Phrase Structure Grammar (GPSG) and the Lexical-Functional Grammar (LFG), which are closely interrelated and used within computational linguistics. They are much more directed towards surface-structure and require more formal semantic interpretations of structures than GB.

An important parallel to generative grammar was *generative phonology*, which operated in a succession of phonological rules. The presentation of phonological processes was very abstract and segmental. There have been challenges to its abstractness and elaborations of more complex phonological representations than originally presented. Of these, autosegmental phonology has already been mentioned as also drawing on Firth's views and those of the London School. Among other elaborations, *lexical phonology* may be mentioned; it is concerned with the relationship between phonology, morphology and lexicon and claims that all morphological and many phonological processes take place in the lexicon, with so-called lexical and post-lexical phonological rules operating.

Morphology did not constitute a separate unit in generative grammar until 1970, but was treated as a part of phonology and syntax. Chomsky gave it the first specific role in 1970, and in 1973 Halle produced the first model of *generative morphology*, which is morpheme-based and works inside the lexical component of the grammar. This model has since been elaborated on.

Among other linguistic theories current in the twentieth century, Halliday's systemic grammar has already been mentioned as expanding Firth's work. It also draws on Hjelmslev, the Prague School, and others. It constitutes a type of functional grammar describing the manner in which grammar is organized to make meaning. Because of this, its use in educational, computational, and text linguistics has been extensive.

*Stratificational grammar*, studied by Makkai and Lockwood, was an approach developed by Sydney M. Lamb beginning in the late 1950s on the basis of post-Bloomfieldian theories and Hjelmslev's glossematics, adopting from the former the notion of the distinction between (a) possible combinations between morphemes and phonemes, and (b) the system, which described the realization of morphemes in terms of phonemes. This produced a two-stratum model dealing with morphemes and phonemes (phonology) through a morpho-phonemic system. From glossematics came the concern with content and expression, with texts rather than single sentences, with the relationship between linguistics and semiotics, and with the concept of language as a network of relations. The two-stratum model was expanded with the four-stratum one containing sememes (semotactics), lexemes (lexotactics), morphemes (morphotactics), and phonemes (phonotactics). Influenced in part by Halliday's *Systemic Grammar*, a notation for the representation of linguistic structure as a network of nodes and lines was devised. Stratificational grammar intends to give a description of language, which can constitute a basis for a performance model.

A general theory of *tagmemics* was presented by Kenneth L. Pike. Tagmemics uses the concept of *slots* (positions) in a structure, filled by classes of items. The final development of tagmemics is a four-cell tagmeme, which encompasses the levels of the hierarchy from conversation to phonology and reaches out to events and situations. Semantics is in all hierarchies, with the native informant part of the database. Language is assumed to consist of form/meaning composites within a culture or society. The concepts of *Emic* and *Etic* (in analogy to phonetic) are used to describe native reaction to elements. Pattern is regarded as more basic than logic. Tagmemics is particularly significant because members of the Summer Institute of Linguistics have been using it in many of their descriptions of exotic languages in the Americas, Africa, continental and insular South-East Asia, the Philippines and Taiwan, New Guinea, Australia and other parts of the Pacific; much of the extant material in and studies of such languages is accessible only through tagmemic descriptions.

Outside the predominant preoccupations of twentieth-century linguistics with internal linguistic factors and principles lies the 1986 study of *pidgins and creoles* by Mühlhäusler. No longer neglected, these languages are proving significant to linguistics in general, to the study of language change and to the realization that there are greater numbers of mixed languages than was recognized before. In pidgin and creole languages, change has occurred very rapidly; this development constitutes a serious challenge to some basic tenets of historical/comparative linguistics – namely that all languages can be genetically classified and that language mixture is a limited and very rare phenomenon. Pidgins and creoles owe their origins to non-genetic development, and they are not suitable for genetic classification and reconstruction. These languages show very clearly the importance of social context in language change. Work during the last few years has been increasingly concerned with the study of pidgins, creoles, and heavily mixed languages based on exotic languages, with interesting results.

The highlighting of social context brings *sociolinguistics* into focus, and especially in highlighting the role language plays in communities where two or more languages are used, and in what Haugen terms *language planning*, which constitutes a systematic response to language problems. Sociolinguistics looks at the creation of new alphabets, standardization, codification of morphology, modernization, language maintenance, and questions of the use of two or several languages side-by-side in a given country or area, or the role of minority languages. For instance, since the 1970s, Australia has changed its policy on minority languages from assimilation to multiculturalism. There is increasing pressure in many industrialized societies for linguistic pluralism and the emergence of new social functions for minority group languages.

In recent decades, there has been an increasing interest in the study of exotic languages in many parts of the world. For

instance, scholars of the former USSR such as B. Serebrennikov contributed many studies of minority languages in that country. V. Solntsev studied eighteen previously unknown minority languages in Viet Nam. In their contributions to the Canberra series on *Pacific Linguistics*, linguists have published many detailed descriptions of languages in the Pacific region and South-East Asia, and Amazonian languages in South America. This research trend has received a strong boost as more and more linguists come to regard language as an intrinsic part of the culture and society of its speakers and realize that each language and speech community reflects a unique worldview and way of thinking. Culture is reflected in the semantic and structural patterns of each language, with each language offering new insights. This realization has greatly increased interest in the study of endangered languages,[1] because with the death of a language, an irreplaceable part of our knowledge and understanding of language is lost forever. In 1993, UNESCO supported a programme to study endangered languages called the *Red Book of Languages in Danger of Disappearing*. It sponsored the production of a small pilot *Atlas of the World's Languages in Danger of Disappearing* in English, French and Spanish. The Permanent International Committee of Linguists (CIPL) and UNESCO itself, through its International Council of Philosophy and Humanistic Studies (CIPSH), assisted a number of studies on endangered languages, with the results to be published. At the same time, linguists and organizations like UNESCO are taking much more interest in the preservation and maintenance of endangered languages, and the revival of moribund ones.

The simplification of many characters in the Chinese alphabet may be mentioned as a special achievement; the feat gave a great boost to literacy in China. This and the rapid spread of the most widely used form of Chinese, known outside China as Mandarin, has greatly increased the possibilities of intercommunication between speakers of mutually unintelligible forms of Chinese.

Finally, the last two decades of the twentieth century witnessed the production of large *language atlases* of use not only to linguists, but also to professionals in related disciplines, and covering China, most of Asia and the Pacific, the Americas and the rest of the world.

## GEOGRAPHY

*Paul Claval*

## GEOGRAPHY IN 1914

Geography differs from other social sciences in the way in which it became formally established as a discipline. Maps, censuses and information about environments being indispensable to the functioning of modern states, cartographic, hydrographic and statistical services, cadastral surveys and weather observation stations appeared in Europe and the United States at the end of the eighteenth and the first half of the nineteenth century. Teaching did not play a decisive role until the 1860s in Germany, the 1870s in France and the 1880s or 1890s in other European countries, when, at a time of deepening nationalist tensions and the scramble by the imperial powers to carve up the world, it seemed vital to teach future citizens about their country, its colonies and the state of the world. Geography featured prominently in curricula from primary school to university.

Academic geography aimed at scientific rigour. It was modelled on the natural sciences even when dealing with social realities. That tradition went back to the naturalist philosophies of the early nineteenth century, and the popularity of evolutionary theory reinforced the trend.

Physical geography, encompassing the specialized fields of geomorphology, climatology, hydrology and the geography of soils and plant life, occupied a prominent place in many countries; in Germany and Russia the idea of putting particular emphasis on the global study of environments began to make headway.

Geographers who concentrated on social phenomena sought to answer three questions: (a) What human distributions can be observed on the Earth's surface? (b) How can the diversity of landscapes formed by social groups be explained? (c) What are the interactions between people and the environment? The emphasis on one or another of these themes varied from country to country. German geography, the oldest and most prestigious school thanks to the work of Alexander von Humboldt (1769–1859), Carl Ritter (1779–1859) and Friedrich Ratzel (1844–1904), was more particularly concerned with landscapes and regional distributions. French geography, which developed rapidly from the 1890s, under the impetus of Paul Vidal de la Blache (1845–1918), also took regional

structures as a starting point but associated them with people/environment interactions, which it described in terms of life-styles. In the United States, where institutionalization came rather late, Carl Sauer (1890–1975) developed a school between the two world wars, which used the analysis of landscapes to assess the links forged by cultural groups with the environment they inhabited and exploited.

Other countries borrowed from Germany (Russia, Eastern Europe), France (Great Britain, Netherlands, Hispanic countries) or from both of them (Romania, Italy, Scandinavian countries). Outside Europe and the United States, geography had only really reached Japan, which drew its inspiration principally from the German school.

Geography in the late nineteenth and early twentieth centuries was equally involved in making an inventory of the Earth. This task was particularly important for the countries where the knowledge of natural resources and possibilities remained incomplete – the United States, Canada, Australia, Brazil, Russia, etc. This task went on after the First World War, especially in the USSR. The results of these researches were very important, particularly in the cold areas of the two hemispheres: exploration of the Antarctic thanks to the efforts of international teams, and detailed surveys of the North Pole region in Canada, Greenland and Russia led to better understanding of life under extreme conditions and the processes that shape these environments.

## THE DEVELOPMENT OF GEOGRAPHY UP TO THE MIDDLE OF THE CENTURY

The end of the First World War disposed of some of the factors that had fostered the rapid rise of geography as a formal discipline at the end of the nineteenth century. Nationalism in Europe had lost its virulence. The imperialist expansion was over, and many people sensed that decolonization would soon proceed. The communist movement, which had transformed the Russian Empire into the USSR, was hostile to nationalism until the 1930s.

Academic geographers were less interested in current affairs than they had been before the First World War.

Their main concern was to ensure that the discipline flourished. The geography that developed between 1920 and 1940 in Western Europe and between 1930 and 1940 in the United States gave pride of place to fieldwork; geographers mustered the resources provided by official mapping and statistics services, made precise observations and carried out surveys and interviews. Their work was largely concerned with describing landscapes and identifying regional structures. Publications tended to focus on small territories, urban areas or regions. Geographers were more inclined to study combinations of elements deriving from detailed surveys from a synoptic regional standpoint than to carry out comparative studies. French geographers were widely admired and emulated because they were the undisputed masters of the art of describing and interpreting regional patterns, as can be seen from the work of Emmanuel de Martonne (1873–1955) and Albert Demangeon (1872–1940); this was because they had been trained as historians, which taught them to be aware of the slow pace of change. They thus paved the way for the *Annales* school of history.

On the whole, academic geography had little contact with the other social sciences, but its lines of inquiry were not dissimilar to those of history or anthropology at the time: there was a parallel between the geographers' regional approach and the emphasis on the specific features of each period or each culture observed in other disciplines.

New fields of interest emerged. Before the First World War, studies of non-European countries assessed their potential for colonial penetration. Hardly any attention was paid to the problems arising from attempts to exploit environments very different from those encountered in Europe or the United States.

The perspective changed between the wars. The areas under colonial domination were well established – the problem was one of developing them. Planters discovered that soil in hot, humid countries was often poor, and that it eroded rapidly after clearing. The robustness of the natural vegetation was misleading: it thrived in what was virtually a closed circuit and could reproduce with practically no need for any additional mineral input. The methods devised by the local communities to make the most of such difficult surroundings began to be understood. Tropical geography emerged.

In the industrialized world, rural areas had been the focus of attention until the First World War. Urban geography then overtook rural geography. Towns were classified according to size and function, as were the areas under their sway. Walter Christaller (1893–1969) laid the foundations of central-place theory in Germany. The role of urban areas enabled the problems of regional spatial division to be addressed from a new perspective: that of polarized areas.

The world between the wars was unstable. Germany considered the Treaty of Versailles to be unfair; Italy and Japan felt ill-equipped for international competition because they had arrived too late in the race for a colonial empire. These states questioned the international political and economic order. This explains the success of political geography and the attempts in Germany to apply it in practice under the name of geopolitics.

Geography thus branched out into new fields of inquiry in order to prove its usefulness to the societies where it was taught. The main focus of interest was economic: the world was concerned about the unequal distribution of resources since international tensions sprang from the contest for raw materials. Geographers were keen to analyse these problems, but as they had no firm analytical foundations for their studies, the work they produced remained descriptive and had little impact on political or economic decision-making.

In the classical period of its development, then, geography was undeniably enriched by new fields of study. It failed, however, to respond to the most urgent needs of society. In Great Britain and the other countries where coal had formed the basis of industrial development in the nineteenth century, whole sections of the economy began to collapse and restructuring was required. In the United States, the over-brutal exploitation of resources led to ecological crises so acute that the federal government had to intervene – as in the case of the Tennessee Valley Authority, for instance. In the USSR, the emphasis was on the rapid development of new industrial centres further and further to the east in often-extreme living conditions.

From the 1930s, geographers were in demand for regional planning and controlled land-use projects. They were called upon for their expertise in spatial organization, but the talents of naturalists, economists, sociologists, architects and town-planners were also sought. The need for land development became more pressing in the 1940s. With the war over, public opinion no longer accepted that certain regions of the industrialized countries should fail to benefit from the overall prosperity and that in the Third World entire nations were sliding into poverty at a time when technical production capacities were steadily improving.

From 1914 to the middle of the century, geography generally played a more modest role than in either the previous or the following period. That does not mean that it did not enjoy some success. Major regional studies made the discipline better known to the educated public. Everyone had heard of the geopolitical theories or resource analyses produced in great number by specialists in economic geography. The land-use register produced in Great Britain between the wars under the direction of Dudley Stamp (1898–1966) was to prove a valuable tool when it came to planning the war economy.

On the whole, however, a feeling of dissatisfaction spread among geographers. Their knowledge did not respond to the land development needs of contemporary societies. Traditional geography seemed more suited to the rurally based units, which pre-dated the industrial revolution, than the complex industrialized societies.

Geography remained a Western discipline: it was now established in all the European countries. It met with considerable success in the British dominions and reached South America, in particular Brazil. Japan continued to draw inspiration largely from the German model, but developed its own vision of the relations between human groups and their environment. In the USSR, the crushing influence of Marxist orthodoxy diverted many researchers from human and economic problems; in the field of physical geography, the emphasis on the study of environments, already apparent in tsarist Russia, was strengthened.

## RESTRUCTURING AND EXPANDING THE DISCIPLINE

This inward-looking phase was followed, from the 1950s onwards, by a movement of reconstruction and expansion, which brought about a radical change in the discipline. It

was no longer modelled on the natural sciences, and became a social science.

Traditionally, the discipline had been concerned primarily with describing and elaborating typologies rather than with formulating theoretical hypotheses, looking for regularities and establishing a general corpus of knowledge. The studies on spatial economics and the research work carried out by Walter Christaller in the 1930s attracted attention for the first time. The new geography that developed from the mid-1950s in the United States assessed the impact of distance on the distribution of human activities; it also drew on the research carried out before the Second World War by the Chicago School of Urban Ecology to explore the social structure of cities. The change came lastly from systematic recourse to sophisticated statistical methods. Factor analysis efficiently processed the large quantity of data often available to geographers; the interpretation of distributions was no longer dependent on mapping alone: maps were a powerful analytical tool, but reading them was too subjective. Remote sensing provided a direct view of the Earth.

Although the new geographical research began in continental Europe as early as it did in North America, the movement was perceived to be Anglo-Saxon and more specifically American. The new goals set for geography were too far removed from those of the German and French schools for them to accept the new trends without some resistance.

In the international field, the consideration with which geography has been held is evident in the prominence accorded to it in settling various international disputes or problems. Geographers were much consulted during the negotiation of the Treaty of Versailles, in 1919. Later, they intervened for settling borders in Asia, for the definition of sea economic zones in South America and for the protection of the environment. Geographers have also been consulted by their governments for the exact coordinates of cities and strategically sensitive sites of interest to the military.

The new geography of the 1960s supplied satisfactory answers to questions relating to urban and regional land development, and geographers were readily admitted into spatial planning teams. They worked a great deal in developing countries, where their commitment to fieldwork was much appreciated.

The change geography was undergoing made it more easily applicable to a number of topical issues. However, that success deflected researchers from such fields as historical geography, cultural geography and political geography. The new emphasis on economics was considered by many to be a loss; all the more prejudicial as the public was discovering that nature needed protecting. Ecology was becoming firmly established, but physical geography, which had presaged many of its developments, particularly in Germany and the Soviet Union, failed to take full advantage of the new trends.

The new geography movement was soon replaced by others. The importance accorded to economics in the work of the 1960s was judged to be excessive, with its failure to question even the most unjust social situations. A radical current largely inspired by Marxism (David Harvey, born 1935) developed in the Anglo-Saxon countries and spread to the rest of the world: it dealt with the geography of poverty, exclusion and marginality, neglected until then,

and inveighed against the discipline's role in traditional and new forms of imperialism.

That geography was no longer concerned with the causes of spatial diversity was regretted, and this spurred a new interest in human experience as it related to the environment. The new approaches were derived from phenomenology; geography became humanistic. Historical research flourished, as did studies on the diversity of cultures and their spatial associations.

Criticism of the new geography stressed the social and human nature of the discipline, but the accent was not, as it had been in the previous generation, on the search for a unitary structure for the discipline. In the climate of scepticism prevalent in the post-modern era, contending with a large number of different paradigms is no longer considered a handicap.

There has been a revival of interest in the lines of investigation neglected in the 1960s and 1970s, with a growing body of research on the political future of the world. The bipolar system which prevailed after 1945 has disappeared, but no one can be sure what shape the new world order will take. States, which have increased in number as a result of decolonization, are unable to meet the needs of contemporary societies. Regions or cities have to shoulder an increased burden of responsibility, and supranational organizations, such as the European Union, NAFTA and Mercosur are playing a decisive role in economic life.

Geographers are again actively concerned with the environment, studying the way in which traditional societies used and managed resources, looking at the imbalances caused by the modernization of agriculture and urbanization at the local level and drawing attention to environmental damage affecting entire regions. They are increasingly focusing on the global consequences of the destruction of the ozone layer, massive carbon emissions and the resultant greenhouse effect.

These issues involve too varied a body of knowledge and technology to be covered by any one discipline. While the problems of natural geography are attracting more attention than ever, it is not possible at present to define the parameters of a discipline specializing in these questions.

Geography has ceased to be essentially European, even though most scientific research continues to be produced in Europe, North America and the former British dominions of Australia, Canada and New Zealand. Japanese geography is among the most productive and covers all fields of inquiry.

Elsewhere, the predominant lines of investigation took their cue from various sources – French geography in the former French colonial empire, British geography in the Commonwealth, and Soviet geography in the countries that had had socialist regimes. These differences in style explain the difficulties encountered by the Arab world, for instance, in unifying a discipline divided among these various traditions.

The influence of the United States was felt virtually everywhere in the 1960s and 1970s as concepts and methods were Americanized. The new geography, and the radical or humanistic trends that followed it, affected the Soviet Union and Eastern as well as Western Europe.

Geography was one of the first sciences to have been established as an independent discipline, but it did not appear in its modern guise until fairly late in the nineteenth

century. Its success has often come more from the services it has rendered to nationalism and imperialism than from its scientific content. The geography of the beginning of the century offered a rational, positive body of knowledge. The geography practised today gives more room to people's experience of the places they inhabit. It speaks to us of roots and the search for identity. It helps us to understand why conflicts arise from issues of language, ideology and territory as much as from access to resources. It enables us to grasp some of the fundamental concerns of today's world.

The philosophies of progress, which dominated the West from the eighteenth century onwards, gave pride of place to history. Geography did not enjoy similar prestige.

The recent questioning of Western thinking has undermined the historicist philosophies: we have entered the post-modern era. In the disillusioned world in which we live, we no longer dream of a better tomorrow. Each of us strives to live as best as we can here and now. The emphasis now is on the diversity of the world and of ways of living in it and developing it. Geography is thus benefiting from the radical changes in dominant philosophies, and its status has been enhanced in the process.

# APPLIED SOCIAL SCIENCE DEVELOPMENT AND CONSEQUENCES

*Hellmut Wollmann*

In this chapter, we will use the term *social science* to refer to a wide interdisciplinary field, encompassing economics and psychology, as well as sociology and political science. In contrast with what is usually termed *basic social science*, which deals with the quest for empirically and theoretically valid statements about the social reality, the applied orientation of social science is primarily identified with social science knowledge that is socially and politically relevant and applicable. For the purposes of our study, applied and policy-oriented social science will be considered as being synonymous. While concentrating on the evolution of applied social science since 1945, we will begin by briefly summarizing its historical antecedents, since a cursory review will enable the reader to understand more recent developments in this field.

In attempting to analyse and 'explain' the international development of applied social science over time, we will not take up the debate in the field of the history of social science examined in considerable length elsewhere.[1] Instead, by focusing on the evolution and shifts of the epistemic, intellectual and methodological agenda of applied social science as well as on the factors that have shaped it, we will depart from a fairly simple conceptual scheme in which the distinction is made between internal and external factors. While the former are seen as operating from within the social science community impinging upon its agenda-setting and on its ability to supply such applied knowledge, the latter relate to factors outside the (social) science system, that is, they remain in the societal and political sphere and touch only peripherally on the agenda of social science. With this distinction in mind, we shall also speak of the supply and demand side of applied social science.

## APPLIED SOCIAL SCIENCE BEFORE THE TWENTIETH CENTURY

An early precursor of an applied social science stance can be traced back to eighteenth-century continental Europe and particularly to Germany's quasi-sovereign states under absolutist rulers eager to make use of the entire body of contemporary scientific knowledge in ruling their emergent states and training their public servants. Under different, but largely synonymous terms – cameral sciences (*Kameralwissenschaften*), policy sciences (*Polizeywissenschaften*) or 'state sciences' (*Staatswissenschaften*) – a body of knowledge took shape encompassing economics, agriculture, finance, statistics, engineering, natural science, etc. Since the mid-eighteenth century, new professorships on cameral sciences were established at some state universities.[2] Well into the last decades of the nineteenth century, the cameral sciences held a strong position at the universities. Academically, they constituted an attempt to systemize and empirically enrich existing knowledge about the contemporary state and statecraft.[3] At the same time, they had an acknowledged practical orientation. Towards the end of the nineteenth century, however, state sciences abruptly disappeared from the universities. Owing to the period's prevailing liberalism and its claim to push back the semi-authoritarian state to a 'law and order' function and to tie it to the rule of law (*Rechtsstaat*), legalism and legal positivism prevailed in the university training of the would-be public servants. Thus, the camaralist policy sciences, which in some way anticipated the 'policy sciences' heralded by Harold Lasswell more than a half-century later, fell into decay without leaving a noticeable imprint on the future development of the applied social sciences.

During the nineteenth century, the unprecedented misery of the urban working class in the wake of early capitalist industrialization and urbanization prompted bourgeois reformers, academics as well as practitioners associating outside the universities, to conduct empirical investigations on social questions in order to persuade governments and parliaments as well as the general public to embark upon social policies. In Britain, reform-minded individuals, often belonging to the Victorian establishment, met in private reform societies, such as the famous and influential Fabian Society.[4] In Germany, historically and empirically oriented economists founded the Association for Social Policy (*Verein für Socialpolitik*) in 1873 with the reformist aim to induce the government to tackle social policies through empirical studies on the potentially revolutionary social question. Since this association, in its early phase, included Germany's most noted social scientists

among its members (including Max Weber), a good many investigations carried out under its auspices turned out to be studies that were explicitly policy-oriented and, at the same time, conceptually as well as methodologically innovative and sound. Thus, the *Verein für Socialpolitik* was considered as a model by many foreign scholars, including early protagonists of the social sciences at American universities.

In the United States, social science research was also distinguished by a reformist and ameliorative orientation, and by the pioneering role played by the American Social Science Association, established in 1865. It embraced the notion that the social scientist was to be a model citizen helping to improve the life of the community, not a professional and disinterested researcher.

## THE FIRST HALF OF THE TWENTIETH CENTURY – THE DEVELOPMENT OF APPLIED SOCIAL SCIENCE IN THE UNITED STATES AND EUROPE

In the United States at the end of the nineteenth century, the applied orientation was adopted and integrated into the further development of the university-based social science disciplines, owing to a number of internal as well as external factors, which set the American social science disciplines on a course conspicuously different from that of their European peers.

Internally, the social sciences disciplines, at an early stage, attained a significant degree of institutional consolidation and recognition within the emergent American university system, undoubtedly owing to the fact that a growing number of universities established distinct departments devoted to social science disciplines (sociology, political science, etc.). This was probably the most important institutional development in the history of the American university system. Furthermore, very quickly, each social science discipline began publishing its own national and professional journal.[5] Benefiting from institutional protection, specialists in these young disciplines saw no need, in contrast with their European peers, to sever the link between the scientific and the applied orientation of social sciences as a price for academic recognition. In addition, the applied orientation was fostered by America's prevalent philosophical pragmatism.[6]

In the 1920s, the applied orientation of social science was further implanted in the American research tradition thanks largely to the efforts of two professors at the University of Chicago: Charles Merriam in political science and Robert Park in sociology. Merriam and Park contributed to instilling the highest methodological standards in social sciences while retaining a policy orientation, their principal goal being to introduce 'more intelligent and scientific technique into the study and practice of government'.

Beginning in the 1920s, the United States Government increasingly sought advice in the fields of social science, and in the early 1930s the Roosevelt administration, when embarking upon its New Deal reforms, brought social scientists into government on an unprecedented scale, thus establishing a close relationship between government and the social science sector.

The European situation was markedly different. The applied orientation of social science in European countries remained unaffected by the development of university-based social science owing to various internal and external factors that differed significantly from the American context. First, on an institutional level, the social science disciplines advanced very slowly. Few sociology professorships were created, since the field remained linked to the departments of philosophy or law.[7] While the emergent European social science field produced pre-eminent scholars (e.g. Emile Durkheim in France and Max Weber in Germany), the precarious institutional status of these specialists along with their claim to scholarly recognition within the universities and the science system at large induced the university social scientists to promote 'truly scientific' (i.e. value-neutral and theory-driven) social science and to reject any applied orientation and so-called 'non-scientific' or 'moralizing' approach. The 'value-neutrality' debate triggered by Max Weber and the creation of the German Sociological Society in 1909 to counter the 'moralizing' Association for Social Policy are two cases in point. Except for the economists whose analyses and advice European governments increasingly turned to amidst the economic turbulences of the inter-war years, European university-based social science, by and large, abstained from an applied orientation well into the 1930s.[8]

## THE DEVELOPMENT OF APPLIED SOCIAL SCIENCE AFTER THE SECOND WORLD WAR

### 1945 to the early 1960s: the applied orientation of social science in retreat?

In the United States after 1945, the applied orientation of social science seemed destined to further ascendancy. Indeed, already during the First World War, economists, psychologists and sociologists were involved in the war through their various analytic, logistic and morale-building activities thereby enhancing the reputation of applied science. Explicitly alluding to this war experience in the early 1950s, Harold Lasswell and his associates made a plea for 'policy sciences with a policy orientation' and recommended combining the study of policy process, conducted with the most advanced methods, and the accumulation of all pertinent interdisciplinarily knowledge, on the one hand, with the application of this synthesized scientific expertise to the policymaking process, on the other. Focusing on 'the fundamental problems of man in society rather than ... the topical issues of the moment', they hoped to develop a type of 'policy sciences of democracy, in which the ultimate goal is the realization of human dignity in theory and fact'.

Yet shortly after this grand design was articulated, it was quickly submerged by the powerful current of the 'behaviouralist revolution', which seized the American social science scene in the 1950s. On the one hand, by calling for the use of quantitative methods based on new computer techniques, the new behaviouralist creed subscribed to conducting social science research in a 'truly scientific' manner consistent with the approaches of Charles Merriam and Harold Lasswell. On the other hand, the behaviouralist revolution, which truly revolutionized the American social science research tradition, programmatically severed the link between the scientific rigour of social science and its

applied orientation. A virtual conceptual 'bulwark against the Lasswellian tide of policy science' thus emerged. Consequently, throughout the 1950s, under the influence of the dominant behaviourist creed, America's mainstream social science pursued an agenda based on value-neutral and, hence, non-applied research.

Like the United States, the countries of Western Europe and Japan appeared to embrace the applied orientation approach to the social sciences after 1945. In what has been called a 'mythical promise of societal renewal through the social sciences', social science was expected to make a decisive contribution to the intellectual and moral rebuilding and revitalization of the war-stricken countries, including Germany and Japan, where the role of social science was considered particularly crucial to the reconstruction of democratic societies.[9]

Institutionally, throughout Western Europe and Japan, the university-based social science disciplines expanded markedly after 1945 by the establishment of new university positions. Yet, the new social science scholars and the financial resources remained limited, and studies in these fields continued to be based on the traditional 'single chair' principle and integrated into the traditional faculties of philosophy or law.

Even more importantly, the university-based social science disciplines, while still in a formative and precarious institutional and disciplinary stage, remained under the influence of American behaviourialism and its ban on the applied orientation, thanks largely to an entire post-war generation of European and Japanese social scientists trained in America. Moreover, in the immediate post-war period, European governments showed little interest in seeking advice from social scientists (except as regards the field of economics). This can possibly be explained by the amazing speed of post-war recovery, which did not create a need for such advice; or the fact that conservative governments, such as in Japan, viewed university-based social science with scepticism, and in certain cases hostility.

In the course of the 1960s, the agenda of social science was dramatically reversed towards the applied orientation in an unprecedented process of institutional expansion and cognitive reorientation. Again, several 'internal' and 'external' factors drove this development. First, we should note the dramatic expansion in terms of personnel and resources experienced by many universities, and particularly in the social sciences in the 1960s, when, in the wake of the 1957 'Sputnik shock', Western countries embarked upon sweeping educational and university reforms in order to catch up with the presumably more advanced Soviet Union in the fields of education and scientific research. Particularly in the European countries, where the institutional expansion of the social sciences after 1945 had been significant, albeit limited, the further boost beginning in the 1960s improved the institutional conditions for a favourable development of applied social science.

Among the most important 'internal' factors shaping the international social science agenda was a shift in the mainstream discourse of the American social science disciplines. This dramatic switch away from the behaviourialist value-neutrality back to the problem-oriented tradition of American social science occurred in the 1960s, when, in view of an increasingly problem-fraught national agenda (poverty, race riots, Vietnam War), a growing number of social scientists called for an end to the value-neutral policy-detached orthodoxy of behaviouralism and in favour of the societal and political 'relevance' of the research agenda.[10] A broad range of research approaches ensued which, mostly pursued by university-based researchers, focused on public policies from different conceptual perspectives, encompassing, e.g., (quantitative) policy-output research as well as (case-study type) implementation research. Before long, this cognitive reorientation of the social science discourse and agenda was adopted by social science communities in Europe.

While the internal debates of the social science communities influenced by the American approach led to the 'rediscovery' of the applied and 'relevant' research agenda, far-reaching changes were taking place in the political environment and in policymaking, which in turn fostered the institutional as well as cognitive development of applied social science on an unprecedented scale.

The advent of a new policy model and its repercussions on the social science agenda can be distinguished by two interrelated characteristics. The first concerns the transition from a laissez-faire type of state and policy model prevalent in the immediate post-war period to the full-blown interventionist welfare state model with its ambitious twin goals of continuous growth of the economy and the common wealth. Embedded in the context of economic growth and fiscal abundance, the belief was widely shared that the two goals should (and could) be achieved by implementing Keynesian economic policy through demand management, on the one hand, and interventionist social (as well as infrastructural) policies essentially based on planning and information tools, on the other.

This concept of interventionist policymaking went hand in hand with the belief that the proper use and involvement of the (applied) social sciences would pave the way towards a new rational model of policymaking in which the scientific analysis of economic and social developments would lead to a single, scientifically based policy choice and decision. Proclaiming the 'end of ideology', it was assumed that the increasing scientific insight and enlightenment of political and social actors (and stakeholders) into the 'objective' reality of society and its problems would induce them to renounce the hitherto prevalent political logic of policymaking based on ideological and interest-laden conflict resolution and would increase the chances of reaching a non-ideological consensus founded on social scientific expertise and an underlying scientific logic. This vision of a science-driven policy model and of an ensuing 'scientificability' of the policymaking process was epitomized by Donald Campbell's famous call for a society with 'reforms as experiments' with the intrinsic neo-positivist science model and Karl Popper's vision of attaining societal progress through piecemeal (social) engineering as its intrinsic epistemic underpinning.

In the United States, its advent can be associated with the increasing range of federal social policy programmes (such as the War on Poverty) created under President Johnson from 1964 onward. Reform policies in such areas as education, civil rights, and social policies were conceptually guided by social science theory. Evaluation research on the process and effects of social intervention programmes, often mandated by federal legislation, became part and parcel of national policies, and massive government spending on the commissioning of such research and evaluation became a

virtual growth industry. Large-scale social experimentation was initiated.[11]

Among the European countries, West Germany shifted to a full-blown welfare state and scientific policymaking model that bore the mark of the Social Democratic parties in the late 1960s. Social scientists participated in policymaking and formed virtual 'reform coalitions' with reformist politicians and administrators on an unprecedented scale. The West Germans developed evaluation research early in the process, and social experimentation was undertaken on a scale unparalleled anywhere outside the United States, placing West Germany in the forefront in Europe.[12] In some other European countries, the development of policy-oriented social science was more continuous. In Sweden, for instance, policymakers possessed much experience in interacting with social scientists. Yet, Sweden, too, underwent a kind of rationalistic revolution. New techniques of systems analysis, programme budgeting, social indicators, commissioned sectorial research, and even future studies were applied to policy problems in all areas of government activity.[13]

Governments' new demand for applied social science expertise was expressed in the following ways:

- The budgetary resources earmarked for commissioning and funding analytical work increased dramatically, thereby creating and sustaining a contractual research money market on an unprecedented scale. At the same time, traditional funding of university-housed basic research began to encourage basic research to move more strongly towards an applied orientation ('applied basic research', *angewandte Grundlagenforschung,* to refer to a hybrid term used at that time in the official language of social science policy, for instance in Germany).
- In increasing numbers, advisory commissions and bodies were set up for involving social science expertise in policymaking and policy-implementation.
- Within governments and administrations, new units and staffs were created to conduct, commission, monitor, and/or implement social science research. Similarly, governmental or quasi-governmental research institutions were established or expanded to strengthen the analytical capacities of government.

Reflecting the consensus widely shared by the period's reformist political and administrative actors and social scientists, the policy-oriented social science research undertaken at this stage can be described as largely accepting, if not supporting, the policies under scrutiny and designed to optimize the performance of the given policies and programmes.

In this period, a broad gamut of conceptual approaches and analytical tools of applied social science were advocated and employed. The following is a summary of some of the most noteworthy:

- *Systems analysis* uses decision-making criteria, assumptions and models mainly derived from economic theory to prepare in advance (*ex ante*) government decisions on complex policy measures and programmes. It falls mainly within the competence of economists. The umbrella term *policy analysis* is often used to designate these 'forward-looking', *ex ante* approaches and techniques. System analysis typically employs cost-benefit analysis. The classical example is the concept of Programming Planning Budgeting

Systems (PPBS), which was introduced in the United States in the mid-1960s. This set of instruments, which claims to provide analytical transparency, if not certainty in making decisions and choices, was at the core of the rationalist revolution of the 1960s.
- *Operations research* (OR) is chiefly rooted in mathematics and engineering and, being primarily an *ex ante* technique, uses sophisticated models and simulations to optimize solutions in complicated and uncertain situations.
- *Evaluation* has become a mushrooming field of applied social science, as governments routinely turned to evaluating public policies and standard operational procedure in policymaking. Backward-looking or *ex post* evaluation has been typically directed at analysing whether, and to what degree, the goal of a policy programme or measure was reached and whether the observable change was causally related to the policy programme and measure under scrutiny. *Ex post* evaluation is typically conducted after the programme's termination. As evaluation research, designed to measure effects and to identify causal relations, is essentially confronted with conceptual and methodological problems characteristic of empirical social science at large, it has been conceptually and methodologically inspired largely by psychology and sociology, including their claim to methodological rigour in a quasi-experimental and experimental vein.[14] Noteworthy examples are the large-scale social experiments and evaluations begun in the late 1960s and early 1970s. By and large, evaluation research has been carried out by research institutions of the entrepreneurial (for-profit) type outside the universities.[15]
- *Policy studies* is used as a rather general term comprising a broad range of studies focusing on policies, such as (internationally as well as intra-nationally) comparative research on policy-outs and public policies as well as research on single phases of the policy processes, such as budgeting and implementation.[16] Such studies are typically conducted by university-based political scientists and usually funded from university resources or through research funding from such institutes as the US National Science Foundation. Because of their explicit policy orientation, policy studies may be classified as perhaps the most important category of university-based applied social sciences.
- *Public administration* (PA) or administrative science. In the United States, PA was originally seen as centring on normative principles concerning the management of public administration with few social science underpinnings. As a result of the behaviouralist revolution of the 1950s, the development of PA was strongly shaped by the expansion and proliferation of graduate programmes in public policy at renowned universities in response to a growing demand from the public as well as the private sector. In Europe, at least in those countries with a strong legal tradition, administrative science was seen, since the end of the nineteenth century, essentially as subsidiary to administrative law. As part of the upsurge of applied social science, the 1960s witnessed a significant growth of social science-based administrative science.

## Development since the mid-1970s

The heyday of the interventionist welfare state policies proved to be short-lived, when, following the rise in oil prices in 1973, the world economy slid into a deepening recession, and national budgets dwindled bringing most of the cost-intensive reform policies to a grinding halt. The two key assumptions on which the (Social Democratic) interventionist welfare state and the upsurge of applied social science had been premised seemed to be profoundly shattered: first, the belief that, through appropriate policy instruments hinging on planning and information, the policy corridor towards continuous economic growth could be secured, and secondly, that reaching and remaining in this policy corridor could essentially be achieved by the 'scientification' of policymaking.

In the political arena, conservative and neo-liberal criticism of the so-called excesses and the crisis of the welfare state quickly gathered momentum in the course of the 1970s, attracted electoral majorities and, in fast sequence, brought conservative governments into office, particularly in the United Kingdom (1979), the United States (1980) and West Germany (1982). In the face of such conservative 'regime shifts' in key countries, the stage seemed to have been set for not only pushing back the expansive Social Democratic welfare state and replacing it with a neo-liberal minimalist state, but also undoing the underlying policymaking model, including the advances of applied social sciences.

While leaving aside the question as to what extent key policies of the advanced welfare state of the 1960s have been dismantled under continuous budgetary pressures and replaced with a neo-liberal policy profile, it needs to be highlighted that, notwithstanding some early political irritations,[17] the incoming governments have largely continued to draw on and fund social science expertise and applied social science research, regardless of their political leanings and 'regime shifts'.[18]

Since the late 1970s, in some countries, including the UK under the Thatcher government, spending on policy evaluation was even increased in what has been called the 'second wave' of evaluation.[19] Since the late 1980s, the evaluation of the European Union's structural funding in member countries has risen to an astounding degree. While the underlying policy model, including its science-driven belief in and attempt at putting policymaking on a 'scientific' footing, has been certainly shattered since the mid-1970s, the governments continue to turn to social science advice and analysis, perhaps even more than ever before, under the current difficult socio-economic and budgetary context. So, Edward Shils' 1965 prediction that the integration of social science advice into the policy process was 'unlikely to be reversed' still stands.[20]

The cognitive agenda, however, of applied social science has changed significantly since the mid-1970s as illustrated by evaluation research and related approaches. While, in the reformist period of the 1960s, the mandate of evaluation research was chiefly to optimize the output and performance of a given policy programme or measure, it now serves to investigate the efficiency and effectiveness of a particular public policy with the implicit or explicit goal of reducing its costs, or terminating it altogether. As a result of the attempt to introduce private sector managerialist principles into public sector modernization, the emphasis on 'value for money' and managerialism have become, as in the case of the United Kingdom after 1979, guidelines for evaluation.

## CONCLUSION

After applied social science research emerged in the nineteenth century largely as a research commitment outside the sphere of universities, it became established as a university-based activity in the early decades of the twentieth century in America. Since the 1960s, applied social science has experienced an enormous international expansion, which has profoundly modified the institutional landscape of social science, including the role of university-based research as the hitherto prime locus of social science research. From the 1960s onward, four sectors can be distinguished in the field of social science research. First, universities remain the traditional centres of research; with studies financed primarily by major funding institutions. Yet these institutions are limited in their capacity to draw on the new 'government-commissioned research money market'. Second, in most countries private for-profit ('entrepreneurial') research and consultant organizations have grabbed the lion's share of the new commissioned research money market. In this context, we should also note the emergence of new hybrid-type research institutes established by researchers at the periphery of their academic institutions, in a somewhat precarious 'shadow zone' between non-profit and for-profit research. Third are governmental or quasi-governmental research institutes conducting research on behalf of the government. Fourth, social science-trained personnel within government bodies are commissioned to monitor research or to conduct analyses themselves, particularly in-house evaluations.

While the applied social science community has expanded on an unprecedented scale, it has undergone a differentiation and specialization along institution-specific, analytical focus-specific, and policy sector-specific lines. In the United States, this ongoing process of professional specialization is evidenced by the establishment of a wide spectrum of professional associations[21] and professional journals, whereas in Europe the process has been lagging.[22] As a consequence of this institution-, focus- and policy-specific differentiation and sectorialization, the discourse within the respective specialized communities tends to be largely limited to their specific issues and approaches, conducted in their particular pertinent policy community or issue community. Composed of the related researchers, research-commissioning agencies and programme managers or beneficiaries, such policy communities may serve as 'iron triangles' prone to conceptually and methodologically – including with regard to funding – 'perpetuate' a type of research along a fixed line.

Thus, the development of applied social science seems to have run into a paradox: while the potentially available research knowledge and 'societal intelligence' has been expanding at an unprecedented rate due to the continuously increasing research findings, the social science community has broken up into an increasing number of specialized and professional sub-communities reflecting a centrifugal rather than a centripetal tendency when synthesizing the interdisciplinary available body of social science knowledge. Meanwhile, the potential of applied social science to

significantly contribute to the theory building of the social science community at large tends to remain untapped.

It should be recalled, at this point, that the policy sciences, as advocated in the early 1950s by Harold Lasswell and his consorts,[23] set out to achieve the Herculean task of compiling the entire stock of available interdisciplinary social science data and of exploiting it in political and societal practice. Notwithstanding the enormous progress, the applied social science community with its diversified sub-communities and professional groupings has yet to realize Lasswell's vision of integrating and synthesizing potentially progressive societal intelligence.

### 'Epistemic drift' of (applied) social science towards the politico-administrative perspective, to the detriment of the 'societal intelligence'

University-based social science has been premised on three imperatives: first, academic autonomy in the selection of the subject matter and the methods of its research; second, independent funding, be it from university sources or through peer-review-based funding; and third, the presentation of the results of findings to open scientific debate and peer-review.

Particularly when commissioned and funded by government, applied social science research is liable to be challenged on all three premises: the subject matter, the leading questions and even the methods of its research pieces are often laid down by the governmental agency when commissioning the research; the government also provides the funding, thereby jeopardizing the researchers' autonomy; finally, the findings of commissioned research are often kept secret, or at least remain unpublished, thus bypassing open public debate and peer examination. Consequently, applied social science, particularly commissioned research, may succumb to 'a colonization process whereby the bureaucracies' perspective and conceptual framework',[24] may overtake it.

University-based social science research of applied orientation has also been criticized, particularly from within the discipline, as undergoing such 'colonization', since, especially in policy-related studies, the researcher may, perhaps unconsciously, be disposed to adopt the problem definition, cognitive frame and time-horizon of the researched subject in a political context and, thus, lose the analytical distance indispensable for truly scholarly work.[25]

The loss of cognitive autonomy and the absence of open debate on the methods and results of research entail the risk, from a normative social science perspective, of such research being conducted in a methodologically deficient manner and of falling prey to research institutes – sometimes nicknamed 'Beltway Bandits'[26] – that seek to extract a fast profit from research at the price of poor research standards and quality. But also seen from the perspective of the society's general interests and of enlightened political actors, methodologically sloppy and analytically policy-'obedient' research would seen of little or no value, as it will, at best, reproduce what the political actors already know. Instead, applied social science research that is institutionally enabled and intrinsically disposed to go beyond the often short-term policy frame of the political actors and the 'topical issues' at hand (to use Harold Lasswell's words) holds the promise of

analytically informing and educating on the long-term conditions, problems, and solutions of policymaking, thus contributing to the societal and political 'intelligence' at large.

### Applied social science and policymaking – a link 'unlikely to be reversed'

Leaving the important historical aspects of applied social science and their interface with its societal and political environment aside, the dramatic upsurge of applied social science in the 1960s was embedded in a science-driven model of policymaking based on the assumption that social science-generated knowledge (being *per se* superior to other societal sources of knowledge) was capable of guiding political decision-making, while pushing back, if not substituting, ideologies and interests at the core of the political logic of traditional policymaking. This belief in the 'scientification' of policymaking was most tellingly expressed in Donald Campbell's call for 'reforms as experiments'. For a brief period, it was apparently shared by significant members of the political as well as academic elites.

This belief in the 'scientification' of policymaking was shattered on two grounds. On the one hand, it was recognized that political logic, as distinct from scientific logic, remains deeply rooted in the political process, not only empirically in the real world of politics 'as it is' (which is unlikely to be fundamentally changed because of the innately political conflict between interests about 'who gets what, when, how'[27]), but also normatively, because replacing the political logic by a scientific one would run counter to basic normative principles of the democratic pluralist society and lead to scientific technocracy. While the optimistic belief in the 'scientification' of policymaking – epitomized in the temporary conduct of large-scale social experimentation – disappeared, there was a growing conviction and expectation that the socio-economic and political interests, when claiming to be considered in the policymaking process, need to publicly 'explain', if not empirically 'prove', their specific demands and expose them to the public debate and controversy.

On the other hand, it was understood that, apart from social science having been shown to be unable (vis-à-vis increasingly more complex and changing socio-economic, social and political environments) to produce the expected valid analyses and forecasts, the very epistemic foundation of social science – in terms of the underlying positivist model – came to be questioned along with the claims of the science-driven policy model. Inasmuch as social science research, however committed to objectivity and 'value-neutrality', is liable to be premised on normative, value-bound assumptions that guide the selection of research subject matter, hypotheses and methods, social scientists are bound to be mindful of their research findings being potentially biased by the normative framework of their research. In subscribing neither to the cognitive orthodoxy of positivism, on the one extreme, nor to cognitive relativism of constructivism, on the other,[28] but, instead, following the 'realist scientificism' proposed by Imre Lakatos, the scientific inquiry, in its 'quest for truth', can be seen as an ongoing process of approximation and validation towards the attainment of 'truth' through academic debate and controversy.

It is within this very controversy – in the world of politics, between rival actors and stakeholders, over the political legitimacy of their interests, and in the world of (social) science, between scientists, over the merits and validity of their findings – that the 'two worlds' of politics and science and their 'two logics' touch common ground. Being admitted to, or drawn into, the political and administrative arenas, applied social science has come to play a crucial role in policymaking, particularly in two regards. First, it has been significantly contributing to the pluralization of the political discourse and controversy in that social science-generated knowledge contributes to the information derived from other societal sources (such as interest groups) and competes with them for being listened to in the political process. Second, in abandoning the earlier idea of science-driven policymaking and of a per se ('epistemic') superiority of social science-generated knowledge, the communicative interface of politics and social science may be best captured by Jürgen Habermas' 'pragmatic' or 'dialogue' model in which politicians and social scientists talk and listen to each other in a mutual learning process. Inasmuch as the social scientists can be confident that their 'arguments'[29] – particularly those of the long-term, complex 'contextual' and not of the short-term, 'topical'[30] variety – find their way into the political and societal learning process, this may result in the 'scientification' of policymaking, in a process that is 'unlikely to be reversed'.

## NOTES

1. For a detailed account of this debate, see Wittrock et al. 1991, p. 28 ff.
2. See Maier 1965. The competency university students were expected to acquire is revealed in an administrative instruction of 1808 in Prussia according to which a student of the cameral sciences 'must have studied the state sciences and related disciplines, particularly policy sciences (*Polizeywissenschaften*), technology, statistics, experimental physics and chemistry, botany and economics' (quoted from Friedrich 1970, p. 36).
3. The state sciences, incidentally, made a great impression on the young American social scientists who, during that period, studied in great numbers at German universities. 'For them (to quote from Somit and Tanenhaus 1982, p. 8) *Staatswissenschaft* was like a breath of fresh, spring air (sic! HW). It was characterized by carefully defined concepts and a comparative, systematic, and highly professional analysis of data. In stark contrast to the ethically oriented, didactic political science of their undergraduate experience, *Staatswissenschaft* encouraged their belief that inquiry akin to that of the natural sciences could ultimately uncover the laws underlying political evolution and development.'
4. M. Bulmer, 'National Contexts for the Development of Social-policy Research: British and American Research on Poverty and Social Welfare Compared', in P. Wagner et al. (eds), *Social Science and Modern States*, Cambridge, UK, 1991, p. 161.
5. American Historical Association (1884), American Economic Association (1885), American Statistical Association (1988), American Academy of Political and Social Science (1889), American Sociological Society (1903), American Political Science Association (1903) (see Somit and Tanenhaus 1982, p. 22 f.).

6. As the noted contemporary German sociologist Karl Mannheim remarked, 'the typical problems of American sociology (arising) from the immediate necessities of everyday life. The American scholar is no bookish person; he maintains contact with criminal courts and social welfare institutions, lives with gangs, in slums and ghettos' (Mannheim 1932, p. 186 ff).
7. In Germany, for instance, prior to 1914, no university chairs in the sociology field existed and only few until 1933, while there was not a single chair in political science until 1933 (Wagner and Wollmann 1991, p. 62 ff.). Similarly, in the United Kingdom before 1945, sociology hardly existed as a distinct academic subject, while political science was mainly philosophical and institutionalist (Bulmer 1991, p. 152).
8. For a more detailed and a differentiating country-specific account, see Wittrock et al. 1991, Wagner 1991.
9. For Germany see Wagner and Wollmann 1991, pp. 69 ff., for Japan, Watanuki 1991, p. 223 ff.
10. See Ranney 1968. It should be noted that David Easton, who in the early 1950s had been a leading advocate of 'purely scientific', value-neutral behaviouralism, later emphatically revoked and reverted this earlier position: 'We can no longer take the ideal scientific stance of behaviourism that, because of the limitations of our understanding, application is premature and must await basic further research' (Easton 1969, pp. 1055–56).
11. For the 'New Jersey Negative Income Tax experiment', as an example, on which the research spending amounted to $8 million see Rossi and Lyall 1978.
12. R. A. Levine, 'Program, Evaluation, and Policy Analysis in Western Nations: An Overview', in R. A. Levine et al. (eds.), *Evaluation Research and Practice*, Beverly Hills and London, 1981, p. 46.
13. See Wittrock et al. 1991, p. 46 ff., Wagner and Wollmann 1996*b* for further accounts on country-specific developments.
14. The 'classic' methods book on evaluation was Campbell and Stanley 1963, both psychologists.
15. The literature on evaluation is virtually endless. For a comparative analysis on the development of evaluation, see Levine 1981, Levine et al. 1981, Wagner and Wollmann 1986*a*, Derlien 1991, for its methodological grounding see, as a 'classic', Campbell and Stanley 1968, for a recent brisk debate of the methodological problems of evaluation research see Pawson and Tilley 1997.
16. W. Jann, 'From policy analysis to political management: An outside look at public-policy training in the United States', in P. Wagner et al. (eds), op. cit., p. 114.
17. In the cases of the United Kingdom and of the United States, where the regime shift was ideologically striking, the Thatcher and Reagan governments, in perceiving the (applied) social scientists as being closely linked with the previous government, were at first set to 'punish' them by the reduction of funding. But these punitive steps turned out to be short-lived episodes.
18. For a comparative analysis as to whether 'regime shifts mattered' in the development of evaluation, see Wagner and Wollmann 1986*a*.
19. Specifically, on United Kingdom see Jenkins and Gray 1991, on West Germany see Wollmann 1989.
20. E. Shils, 'The Calling of Sociology', in T. Parsons and E. Shils (eds.), *Theories of Society*, New York. 1965.

21. See Operations Research Society of America (1952), Policy Studies Organization (1972), Association for Public Policy Analysis and Management (1979), Evaluation Research Society (1977) and Evaluation Network (1979), the latter to merged in the American Evaluation Association (1987).

22. In the field of evaluation, for instance, it was only recently that national associations were founded in the United Kingdom, Italy, Switzerland, and Germany.

## INTRODUCTION

Science, technology and society have experienced tremendous changes in the twentieth century, a period in which humankind has made brilliant achievements in civilization and has been faced with multiple socio-cultural contradictions and crises. As a result, philosophy, which mirrors the spirit of the era, has also undergone profound transformation. Many newly emerged philosophical schools and theories offer a colourful panorama, reflecting the diversity of human culture.

In this chapter we will outline the basic patterns and characteristics of philosophy in the twentieth century: (1) A number of influential philosophical trends originating in Europe and the United States have brought forward a variety of distinctive philosophical doctrines and principal ideas by reflecting on science, culture and social life, while the various kinds of philosophy have also influenced one another to a certain degree; (2) the age-old and diverse regional and national philosophical traditions have maintained their vitality and renewed themselves in an effort to adapt to modern society and culture through contact with exotic philosophies; in addition, they have made important contributions to the development of world philosophy and culture; (3) the critical issues of universal significance posed by contemporary philosophy have determined the current role of philosophy in cultural and social development and foster an examination of the potential of philosophy and human civilization at the beginning of the new century.

## MAJOR PHILOSOPHICAL SCHOOLS OF THE TWENTIETH CENTURY

### Analytic philosophy

Analytic philosophy investigates problems such as facts and knowledge by means of linguistic and logical analyses. Its competition with the humanistic trend of the European continent is a prominent feature of twentieth-century philosophy. Analytic philosophy developed from realism's criticism of the speculative philosophy of Neo-Hegelianism

at the beginning of the twentieth century and is related historically to the philosophical traditions of Hume's empiricism and positivism. Modern logic, which developed during the century, provided it with a powerful thinking tool. The initial objective of analytic philosophy was the certitude of science and knowledge and the explicitness of language. In this respect, analytic philosophy benefited from the work of the German philosopher Gottlob Frege. He criticized psychologism, made distinctions between *Sinn* and *Bedeutung* (sense and denoting), set up the prepositional and predicate calculus system characterized by precise quantification of thinking, and emphasized that logic is the starting point and primary tool of philosophical studies, thus promoting the 'linguistic turn' in modern philosophy. British philosophers Bertrand Russell (Plate 103), George Edward Moore and the Austrian luminary Ludwig Wittgenstein were the actual founders of the analytic philosophy movement. By using his own comprehensive symbolic logic, Russell created the analytic method of the ideal language school and was well known for 'logical atomism.' His 'theory of description' is praised as a model of analytic philosophy. Moore stood for the restoration of realism, which confirms 'common sense', and sharply attacked idealism. He created the method of conceptual analysis of ordinary language. Wittgenstein advanced two different philosophical theories, which have exerted direct influence on both the ideal language and ordinary language schools. The representative work of his early philosophical theory is *Tractatus Logico-Philosophicus* (1921), in which he raised the 'picture theory', according to which language and the world have the same logical structure, and improved logical atomism with the truth function theory. Contrary to his early doctrine, his posthumous work *Philosophical Investigations* (1953) put forward the 'language game theory' concerning usage and rules of ordinary language and considered language as a 'life form.'

### Logical empiricism and philosophy of ordinary languages

In the 1920s, logical positivism (later called logical empiricism), as a representative ideal language school

represented by the Vienna Circle, brought the analytic philosophy movement to its climax. Principal members of this school were Moritz Schlick, Rudolf Carnap, Herbert Feigl, Otto Neurath, Friedrich Waismann, Hans Hahn, and Kurt Godel. Its inaugural manifesto was *Scientific Worldview: The Vienna Circle*. The Berlin school with Hans Reichenbach and Carl Gustav Hempel as the representatives and the Warsaw School represented by Alfred Tarski held views similar to those of the Vienna Circle. The philosophy of the Vienna Circle was later introduced into Britain by Alfred Jules Ayer, Frank Plumpton Ramsey and others, thus enabling logical empiricism to spread widely in the English-speaking world. It exerted great influence in the Nordic countries as well. Its basic ideas are: (1) strict distinctions should be drawn between analytic and synthetic propositions, and only these two propositions are meaningful and constitute scientific knowledge; therefore, all forms of metaphysics should be rejected; (2) the verifiability principle of prepositional meaning was set upon the basis of empirical reductionism; (3) philosophy is not science, but rather an activity of logical analysis of language that clarifies the meaning of propositions; (4) the advocated principle of physicalism is aimed at establishing a unified science system based on physical language.

The philosophy of ordinary languages was successively inspired by the thinking of Moore and later Wittgenstein; after the 1950s, the Cambridge and Oxford schools were its leading proponents. It objects to the re-creation of ideal artificial language and calls for removing confusion and misunderstanding in the use of language by traditional philosophies through careful analysis of the use of ordinary language. The 'theory of illocutionary force' created by John Langshaw Austin charted the developmental direction of pragmatics. The philosophy of ordinary languages maintains that analysis of languages is closely connected with human behavioural experience, and it can be extended into the ethical and socio-cultural fields without completely rejecting metaphysics. Peter Frederick Strawson created 'descriptive metaphysics' on the basis of his view of performative truth, and he emphasized the study of actual thinking structures in order to provide a conceptual framework for knowledge and ethics.

### Development of analytic philosophy in the United States

On the eve of the Second World War, some principal members of the Vienna Circle immigrated to the United States resulting in the rapid dissemination of logical empiricism, which gradually replaced the predominating pragmatism in that country. American pragmatist philosophy, founded by Charles Sanders Peirce and William James at the end of last century, infused various fields of the humanities and social science by John Dewey in the early part of the twentieth century and formed a complete theoretic system. Pragmatism emphasizes the continuity and entirety of experience and holds that pluralistic and relative truth is a useful instrument for dealing with the environment. Its empiricism and behaviourism are different from logical empiricism, but at the same time, both have infiltrated and interacted on each other. Moreover, logical empiricism significantly enriched logical analysis in the United States. The studies conducted on rationality of

science by Reichenbach, Hempel, and others promoted the development of the philosophy of science.

Since the 1950s, logical empiricism has been gradually declining due to challenges from within and without analytic philosophy and its intrinsic theoretic difficulties. In Britain, it was attacked by Karl Raimund Popper's critical rationalism and falsifiability doctrine. In the United States, Willard van Orman Quine criticized the two dogmas of empiricism – the strict distinction between analytic and synthetic truth and the reductionism of the verification of meaning – and put forth the principle of ontological commitment and naturalistic philosophy of language, thus turning analytic philosophy towards logical pragmatism. He also established the holism of scientific knowledge and the doctrine of ontological relativity. His breakthrough in the basic theoretical framework of logical empiricism has led to the advancement of American post-analytic philosophy and philosophy of science in diverse forms, including the theories concerning the meaning of truth and its interpretations and anomalous monism by Donald Herbert Davidson, essentialism and the possible world doctrine by Saul Kripke, the speech act theory by John R. Searle, internal realism by Hilary Putnam, the historicism on structure of scientific revolution and the paradigm theory by Thomas Samuel Kuhn, pluralism by Paul Karl Feyerabend and neo-historicism by Dudley Shapere. Richard McKay Rorty's neo-pragmatism and the doctrine on culture of post-philosophy represent a radical rebellion against traditions of analytic philosophy and an attempt to merge scientism and the humanistic trends on the European continent.

### Phenomenology and phenomenological movement

Phenomenology is an important philosophical trend that studies human acts of consciousness and stresses the analysis of consciousness, namely, the description of phenomena. It has had a far-reaching impact on the development of philosophy on the European continent in the twentieth century, and its methods of phenomenological description have been put to use in various degrees by other schools such as existentialism, philosophical hermeneutics, and philosophical anthropology. Such applications are collectively regarded as a broad-sense phenomenological movement, which lasted through the century.

### Husserl's phenomenology

The aim of phenomenology, founded by Edmund Husserl, was to determine the definite, necessary and absolute foundation for knowledge. He called for the 'return to things themselves' and stood for an attitude of 'epoché' in making judgements on the existence of the world. This attitude involves describing and reflecting on every phenomenon appearing in the consciousness of the empirical self by essential intuition; probing the meaning and structure of empirical knowledge; studying in depth the intentional structure of transcendental ego and its acts of constructing conscious objects by eidetic reduction and transcendental reduction so as to establish a kind of strict theory of knowledge; and obtaining phenomenological residuum in transcendental reduction, which is pure consciousness, i.e. transcendental ego as the subject of transcendental

phenomenology and the ultimate basis of all knowledge. In his later years, Husserl advanced the *Lebenswelt* (life-world) theory, which holds that according to a teleological explanation of history and owing to the long-standing influential role of positivism and objectivism, European science in the twentieth century lost human subjectivity and the meaning of life. This in turn enabled irrationalism to penetrate science, contributing to an overall crisis of humanity. He believed that philosophy should probe the human life to re-establish a rational basis for the meaning and value of science and life. This doctrine has exerted profound influence on humanistic philosophy in contemporary Europe.

## Existentialism and psychoanalysis

Existentialism finds its theoretic source in the irrationalism of Søren Aabye Kierkegaard and Friedrich Wilhelm Nietzsche in the middle and late nineteenth century and Husserl's method of phenomenology. Its aim is to reveal the authentic existence of human beings and to explore the structure and meaning of human existence. It originated in Germany in the 1920s, became prevalent in France during and after the Second World War, and later spread to other countries. Its main representatives are the German philosophers Martin Heidegger and Karl Jaspers and French philosopher Jean-Paul Sartre (Plate 104). Heidegger, one of Husserl's pupils, deviated from his teacher's theoretic orientation. He pioneered studies focusing on the existence of human beings and elaborated a completely new notion of *Sein* (being). In his most important book, *Being and Time (Sein und Zeit)*, published in 1927, Heidegger criticized traditional ontology and formulated his fundamental ontology, which probes into the meaning of 'being' and 'being-there' (*Dasein*) by means of phenomenology and emphasizes the realization of human existence through understanding the meaning of 'being.' He also pointed out that contemporary human beings are facing a crisis because they have lost the meaning of their own 'being' by conquering and controlling external things. In his later works, such as *Letter on Humanism* (*Über den Humanismus*, 1947), *Forest Trails* (*Holzwege*, 1949) and *The Way to Language* (*Unterwegs zur Sprache*, 1959), Heidegger expounded some key ideas: truth is the 'unconcealedness' of the meaning of 'being', language is the 'home of being' and basic mode of human existence. He also criticized cybernetic consciousness and technological civilization with a non-anthropocentric view.

Jaspers was a theological existentialist. In *Philosophy* (*Philosophie*, 1932), *Philosophical Faith and Revelation* (*Der philosophische Glaube angesichts der Offenbarung*, 1962) and other works, he maintained that existence is freedom and that having discovered the limits of their own marginal existence, human beings could approach the transcendental God. In *Being and Nothingness* (*L'Etre et le Néant*, 1943), *Critique of Dialectical Reason* (*Critique de la raison dialectique*, 1960), and other works, Sartre stressed that the core of existential philosophy is humanism and expounded the principle of 'being preceding essence'. He examined the dialectical relationship between 'being-in-itself' and 'being-for-itself' and between the individual and society and also advocated free choice and assuming responsibility for one's choices. He tried to replenish the human aspects of Marxism

with existentialism. Sartre's philosophical thought was immensely influential because of his literary works and his participation in leftist political activities.

Psychoanalysis, pioneered by Sigmund Freud in the early twentieth century, attempts to discover the secrets of human beings' irrational mental state of unconsciousness. Freud considered the human instincts of self-preservation and sexual desire to be the innate driving force behind human behaviour and the suppression of 'libido' (sexual desire and love) as the root cause of mental illnesses. Moreover, according to Freud, the creativity of human consciousness is able to turn the suppressed instincts into a spiritual force, which is the cornerstone of human evolution and civilization. Neo-Freudians Carl Gustav Jung and others later conducted studies on collective unconsciousness and used a kind of social psychoanalysis to explain social and cultural processes. Psychoanalysis has had a considerable influence on the phenomenological movement and other contemporary philosophical schools.

## Contemporary philosophical hermeneutics

The term *hermeneutics*, which probably derived from Hermes, the messenger of the Greek gods, originally referred to the interpretation of divine commands, but eventually came to refer to a methodology of the humanities. Heidegger's expounding on understanding and language as the basic modes of human existence brought about a shift in hermeneutics, which was henceforth considered in an ontological context. Hans-Georg Gadamer, Heidegger's pupil, has since 1960 published a series of works including *Truth and Method (Wahrheit und Methode)*, thus establishing philosophical hermeneutics as existential ontology. Among the main concepts: as the essential attribute of being, understanding integrates judgement, history and language, thus turning Heidegger's truth as 'unconcealedness' into the main thrust of hermeneutics; understanding, in a historic sense, is considered the dialectical interaction of prejudice and tradition, which have evolved in creative activities to form a consciousness of history. Language is the central issue of philosophy, and by absorbing and transforming the 'language game theory', the existential ontology maintains that the linguistic universality of world experience constitutes a form of life although it possesses ontological priority. French philosopher Paul Ricoeur, in his works including *Le conflit des interprétations*, 1969, and *Hermeneutics and the Human Sciences*, 1981, created phenomenological hermeneutics that merge with structuralist semiology, psychoanalysis and the speech act theory. He maintains that the doctrine on the life-world, transcendental phenomenology and existential ontology can be connected, but cognitive links must be added, and this can be achieved by the analysis of semantical structure of text, which is the focus of hermeneutics. Contemporary philosophical hermeneutics has been widely circulated and studied in Europe, the United States, and other countries.

## Structuralism and post-structuralism

Structuralism originated from the theory of structural linguistics. It is a philosophical trend, which applies the method of structural analysis to the study of social, historical

and cultural phenomena and has been prevalent on the European continent since the 1950s alongside phenomenology and existentialism. Switzerland's Ferdinand de Saussure was the pioneer of structuralism, and in the 1950s the renowned French cultural anthropologist Claude Lévi-Strauss (Plate 105) used modes of structural analysis to study socio-cultural phenomena.

## Early structuralism

In his books, *Structural Anthropology* (*Anthropologie structurale*, 1958), *The Savage Mind* (*La pensée sauvage*, 1962) and the four-volume *Mythologiques* (1964–71), Lévi-Strauss treats all forms of human social acts as cultural phenomena with the properties of linguistic codes. He uses modes of linguistic structural analysis to investigate social structures and cultures of the primitive society, and thus expounds the philosophical theory of structuralism. He conducted studies on marriage and the family system of the primitive society and maintained that social structures and cultural phenomena result from the innate structuring ability of the unconscious in the depths of the human mind. The unconscious is not the irrational instinctive impulse described by Freud, but an intellectual function that exists inherently in the entire human race for constructing conscious cultural phenomena and enables human beings to maintain structures at both the natural and cultural levels. Lévi-Strauss advocated that the task of structural anthropology is to investigate, through people's conscious activities, the integral structure of the unconscious playing a role of conditionality in society and culture, thus rendering studies of social sciences and the humanities as precise as those of natural sciences.

In the 1950s, Swiss psychologist and philosopher Jean Piaget began publishing his three-volume book *Introduction to Genetic Epistemology (Introduction à l'épistémologie génétique)*, in which he studied the origins and the development process and structure of cognition by using structural analysis. He defined *structure* as a dynamic conservation system with integrality, which consists of a number of transformation rules and is capable of self-regulation. He explained that cognition originates from interaction between the subject and object and is in itself a creative constructive process encompassing simple low-level structure to complex high-level structure. Through the homeostasis action of assimilation and accommodation, the subject's cognition patterns are able to gradually approach the structure of the object. And such a constructing process is infinite.

## Post-structuralism

Post-structuralism, while criticizing traditional metaphysics, opposes the ideas of fixed structures and structure centres. As one of its representatives, French philosopher Jacques Derrida established the theory of deconstruction in a series of works including *Of Grammatology (De la grammatologie, 1967), Dissemination (La dissémination, 1972)*, and *The Margins of Philosophy (Marges de la philosophie, 1972)*. He pointed out that the error of 'logocentrism' ran through various kinds of metaphysics and the fact that structuralism is centred on the phonetic actually also falls under the tradition of metaphysics. He held that it is necessary to deconstruct all philosophical systems with structural centres and remove all their socio-cultural sediments and emphasized that the written language, namely the visual letter symbols in space, is superior to the spoken language. The difference between linguistic symbols, according to Derrida, should be a kind of diachronic 'différance' (temporal difference) which is dynamically displayed in 'the experience of life' described by phenomenology. The meaning of language is a 'trace', which can be erased and renewed incessantly, and all written language is the inscription of the trace. Derrida's theory of deconstruction deals extensively with literature, art, and socio-cultural issues, and it has thus exerted an impact particularly on literary and aesthetic theories in Europe and the United States.

## Diversity of structuralism

Structuralism boasts some other influential and distinctive theories. French philosopher Jacques Lacan transformed psychoanalysis with structuralism and believed that unconsciousness possesses a linguistic structure and that Freud's theory of unconsciousness can be re-described in precise terms by the rule of signifier and applied to the humanities in a more flexible and effective way. He maintained that the unconscious is formed in exchanges between the subject and the other (others, and especially via language). Therefore, the unconscious is the discourse of the other and its linguistic structure is the common psychic structure of people. Michel Foucault, another influential French philosopher, studied psychiatry, the history of ideas and socio-cultural issues by unique methods in a number of his books including *The Order of Things (Les mots et les choses*, 1966), thus setting up a theory of discourse and 'archaeology of knowledge'. He held the view that all things and human behaviours depend on the link between words as the internal structure and things as the external phenomenon, their structure in the space of knowledge being 'epitome.' Although the three types of 'epitome' experienced by intelligence and culture in Europe since the Renaissance have their respective principles for organizing knowledge, they are all anthropocentric. The task of contemporary humanities is to create, by analysing human exploration into the nature of life and labour, an epitome which does not take human beings as the central subject but describes only the order of discourse, confirms the unity of rationality and irrationality, and believes in accidental sudden change in epitome and non-continuity of history, thus transforming studies on the history of civilization into a kind of 'archaeology of knowledge.'

Noam Chomsky in the United States produced the theory of transformational-generative grammar. He expounded the surface and inner structures of language and a whole set of rule systems for their creation and transformation. His theory is praised as a revolution of contemporary theoretical linguistics and can be applied to many fields. His universal or philosophical grammar is based on the philosophy of the mind, which combines rationalism and biologic naturalism. It holds that innate linguistic competence and structure are the mirrors reflecting the inherent capability and structure of the human mind, and they are thus genetically inherent in the human brain.

## Marxist philosophy

Born in the mid-nineteenth century, Marxist philosophy has been a developing current with enduring vitality and extensive influence throughout the twentieth century. It persists in the world views of dialectical materialism and historical materialism, stresses practice as the source and basis of knowledge and the criterion for testifying truth, asserts that social being determines social consciousness, and explains all historical phenomena in the light of economics and socio-political relationships. Marxist theory has developed by continuously accumulating the achievements of natural and social knowledge. As a theoretical force of transforming the world, Marxist philosophy has promoted the socialist revolution in a number of countries and become the leading theory in their social ideology. Meanwhile, some thinkers in Europe and the United States have studied, revised and 'enriched' Marxist philosophy in various ways. They have merged it with ideas from other philosophical schools and conducted new critical studies on the social process of contemporary capitalism, resulting in a number of doctrines of so-called 'Western Marxism'.

## Development of Marxist philosophy in socialist countries

G.V. Plekhanov effectively disseminated Marxist philosophy in Russia and made a new contribution to studies on the social structure with historical materialism. Lenin further developed the basic principles of Marxism. He studied the new discoveries and theoretic crisis of natural sciences at the beginning of the century, advanced scientific materialism and reflectionism while expounding the fundamental categories of matter, experience, truth and practice, and put forward the idea of unity between dialectics, logic and epistemology in carrying out in-depth studies on the basic laws and categories of materialistic dialectics. He developed the Marxist doctrine on state, explored the socio-economic structure for the socialist transition period, including the necessity to resort to means such as 'state capitalism', and revealed the special law of the socialist cultural construction, which he claimed must critically inherit and carry forward the fine traditions and achievements of world culture. However, Stalin made some dogmatic interpretations of Marxist philosophy and false assertions on the social reality, which exerted a negative influence upon the socialist cause. Taking into account the particularities of the Chinese revolution and construction, Mao Zedong creatively adapted Marxist philosophy to the Chinese context, by 'seeking truth from facts.' In criticizing dogmatism, he founded the doctrine based on practice and contradiction. He stressed the utmost importance of practice in the active and dialectical epistemology, carried out in-depth studies on the law of unity of opposites, the core of materialistic dialectics. His theory concerning the correct handling of internal contradictions among the people explored basic contradictions in socialist society and the principles for dealing with different kinds of contradiction. His philosophical thinking continues to play a leading role in building a Chinese variety of socialism. Philosophers in socialist countries have been working to absorb the new experience of social practice and new achievements of science-technology and culture while attaching importance to dialogue with their counterparts in other countries in an effort to enrich and develop Marxist philosophy in various branches and fields of knowledge, thus making it a precise and open theoretic system.

## Humanistic philosophy of praxis

The *Prison Notebooks* (*Appunti*, 1929–35) written by Italian social theorist Antonio Gramsci during his incarceration by the fascist regime deals extensively with numerous philosophical, historical, political and cultural issues. He advanced the notion of praxis (action) and in accordance with historicism's 'principle of totality', he maintained that the subject and object, and theory and practice are unified in people's social and spiritual activities. He objected to mechanical determinism in economy and believed social history to be a process in which the economic basis, social politics, and ideology interact in a dialectical way. He criticized capitalist society's control over ideology and culture, called for socialist democracy, stressed the important role of ideology and social culture in the revolutionary struggle and urged intellectuals to form a historic alliance with the masses to establish a new cultural system leading to human liberation and a renewed morality.

In *History and Class Consciousness* (1923) and other works, Hungarian philosopher György Lukacs stressed *praxis* as the central philosophical concept in conformity with the principle of totality and regarded alienation as the main basis for criticizing capitalism. He maintained that the proletariat must acquire a class consciousness of the search for totality, overcome alienation and undertake its own (and humankind's) liberation through activities capable of reforming history. As a result, history also acquires self-consciousness. Lukacs also applied his philosophy to aesthetics and to art and literary theory. His philosophy has had tremendous influence on the theories of 'Western Marxism' and the humanistic trends within the socialist movement.

## Critical theory of society in the Frankfurt school

The Frankfurt school was the most influential and long-lived of the diverse currents of 'Western Marxism'. Established in 1923 as the Institute of Social Research, its main advocates were Max Horkheimer, Herbert Marcuse, Theodor W. Adorno, Jürgen Habermas, and Alfred Schmidt. In 1934, the Institute was relocated to the United States and remained there until 1950, when it returned to Germany. After the 1970s, it ceased to exist as a unified school owing to major divergences among its members.

In its early days, its members denounced fascist dictatorship as the destruction of rationality. However, they later conducted studies primarily on the characteristics and crises of the developed industrial society and contemporary capitalism, which led to their critical theory of society. They claimed that they accepted some of Marx's principles, including the doctrine on alienated labour, to criticize capitalism. Moreover, certain ideas borrowed from existentialism, psychoanalysis, philosophy of ordinary languages and philosophical hermeneutics infiltrated their theory. They criticized technocracy, human alienation and

extracted ideology from the fields of economics, politics and culture. *Dialectics of Enlightenment* by Horkheimer and Adorno presented the 'traditional theory' based on instrumental rationality, which had led to the negative effects of the technological civilization on human beings. Marcuse pointed out that the developed industrial society is a technocratic one-dimensional society, which produces one-dimensional thinking to control ideology. According to Marcuse, one-dimensional man loses his ability to reason and is ultimately reduced to being a slave to material things.

Habermas advanced the theory of 'communication rationality' and attempted to eliminate the 'legislation crisis', reform the social structure, and advocated a lifestyle based on a free communication structure. According to the Frankfurt School, in the contemporary industrial society with its highly developed science and technology, class structure has undergone major changes and the state should play a leading role in social intervention. It further maintains that the transformation of the society should focus primarily on the field of ideology.

## NATIONAL AND CULTURAL PHILOSOPHICAL TRADITIONS

### Indian philosophy

In the twentieth century, Indian philosophy converged with Western philosophy mainly in the areas of analytic philosophy and the phenomenological and existential currents of thought. Many great philosophers in modern India, including Rabindranath Tagore (Plate 106), Mohandas K. Gandhi, Aurobindo Ghose, Krishnachandra Bhattacharya and Sarvepalli Radhakrishnan, were not only well versed in traditional Indian philosophy, but also possessed a good understanding of the philosophies and cultures of Europe and the United States. Most of them were aware of the numerous 'scientific facts' and empirical methods in the modern world and attempted to explain their own traditions from a new perspective. Some of them even returned to traditions after in-depth studies in Western sciences, believing that the principles of traditional Indian philosophy are in some ways linked to those of the other philosophical schools.

Traditional Indian philosophy has its roots in the ancient religious ideas described in the Upanishads and seeks a supernatural value or the value of the other world by adopting a meditative and superrational attitude. Influenced by this Vedantic tradition, modern Indian philosophy is basically monistic; however, under the impact of Western thinking, Indian religious philosophy has acquired secular aspects. Radhakrishnan, as the principal interpreter of a reconstructed *Advaita*, believed that when 'reality' relates to itself or is regarded as an infinite possibility, it is the 'absolute' objective sought after by philosophy, yet when 'reality' relates to creation or to the possibilities lying within forms of creation, the 'absolute' becomes the creator, wisdom, love, good and the god, as the goal of religion. Some Indian philosophers maintain that although the god can exist without the world, it is nonetheless real because it is determined by the will of the god, thereby proving its existence. It follows that man and the empirical world of his subsistence are closely related with the transcendental reality, and the developmental order of corporeality is not

mechanical, but seeks to realize a particular goal. Therefore, repression of the corporeal nature would destroy the supreme spiritual reality. While trying to redefine Vedantic ideas, Ghose pointed out that only in corporeality can ego develop and interrelate with 'the universal beings' or the ego of all other individuals and can human consciousness and existence continuously grow and develop until they eventually reveal their identity with the god. As a result of this change in their basic position, modern Indian philosophers no longer pay attention only to the transcendental field to the neglect of experience and rejection of secular considerations. They reconcile the two and call for training human beings, by means of philosophy and adopting a new attitude towards living and observing the world. They believe that once people understand through the acquisition of philosophical knowledge that they are unified with all other things, their disposition will immediately change. They have given modern explanations to a number of key concepts of Indian philosophy, such as *karma*, *rebirth*, *eternal life*, and *deliverance*. Ghose and others explain *karma* from an existentialist perspective: this obstacle to our own freedom is created by ourselves and although we are indeed restricted by *karma*, we are also able to create a future and realize full freedom after the obstacle is removed.

Tagore and Radhakrishnan analysed various situations in the realm of human existence – life's suffering, anxieties and fears – and asserted that human beings will obtain the true meaning of life if they live in them and do not complain about them. Gandhi maintained a philosophy of non-violence. He repudiated violence as the law of brutes, because it causes pain to any life as a result of anger or selfishness. Gandhi praised non-violence as the law of our species because the basic principles of non-violence are based on the principle that what is good for oneself is good for the entire universe as well. He explained that non-violence did not mean surrendering to evil; neither does it mean compromising with violence. This activist interpretation of non-violence greatly enriched the Indian notions of quietism and negation. While ancient Indian philosophy concentrated solely on living to escape reality, modern Indian philosophers stress the connection between philosophy and the secular life. Modern Indian philosophy maintains that philosophy is able to foster a world view, and therefore, it contains both highly rational analysis and positive inspirations for behaviour and lifestyle.

In the epistemological field, modern Indian philosophers have been influenced by Western theories of knowledge as well as their own traditions. However, most of them are unable to totally accept methodology dominated by Western scientific reasoning, and they stress that we eventually must grasp reality by understanding the *supermind* and *superself*, even though they admit that sensory experience and rational cognition can be useful as sources of knowledge about life. Radhakrishnan pointed out that rational thinking takes the duality of the subject and object as its premise and that to understand the monistic reality, this cognitive process separating the subject and object of cognition cannot be used. Bhattacharya noted however that 'cognition' has never been a passive state, but rather an activity displaying the subject's free association with the object; it can thus be inferred that science is not cognition because it always cuts its ties with the subject and stresses only factuality and objectivity. Some other modern philosophers, influenced by

Henri Bergson, no longer regard intuition as a kind of mystical capability, but treat it as perfect types of mental activities, which are able to extend and deepen the process of perception to areas not accessible to sensory organs. In intuitive comprehension, the difference between the subject and object disappears as their duality vanishes.

## Chinese philosophy

In 1911, the last Chinese feudal dynasty was overthrown, and in February 1912 a republic was established. Philosophy in twentieth-century China has witnessed a process of fusion or dialogue between modern Western philosophy and China's traditional philosophy. Western philosophy was first introduced to China in 1897 with the translation of Huxley's *Evolution and Ethics*, which was rapidly followed by the translation of the works of Spencer, Darwin and others. At the turn of the century, the writings of Schopenhauer, Kant, Nietzsche and Rousseau appeared in China. In the following decade, important works by Bacon, Descartes, Spinoza, Berkeley, Hume, James, Bergson, Russell, Dewey, Marx, Bakunin, and Kropotkin (the advocate of the philosophy of anarchism) were available in China. As interest grew, Dewey was invited to lecture in 1919 and 1920 and Russell in the following year; each school had its champions and detractors among Chinese thinkers.

Some of the Western thought heavily influenced the 1911 revolution and the New Culture Movement. For example, Sun Yat-sen (Plate 107), the leader of the 1911 revolution, was an exponent of Darwinism. His ideas of *Tienhsia Weigong* (the world belongs to its people) and *Tienhsia Datong* (the great unity of the world) were obviously a fusion of evolutionism and Confucianism. Hu Shi, a pupil of Dewey and one of the initiators of the New Culture Movement, faithfully followed Dewey in the conviction that truth is an instrument to cope with actual situations, and he advocated 'more investigation of problems and less talk about theories'. Li Dazhao, the co-founder of the New Culture Movement, first introduced Marxism to the Chinese youth and greatly promoted the movement.

Marx's materialistic interpretation of history became a fashion in the late 1920s, and after the mid-century it became the mainstream philosophy in China. As an open system, Marxism has incorporated China's local context and the positive aspects of traditional Chinese philosophy as well as certain great achievements of foreign civilizations. In the early twentieth century, traditional Chinese philosophy, comprising mainly Confucianism, Buddhism and Taoism, also renewed its content and form through encounters with Western philosophy. After conducting thorough comparative studies on Oriental and Occidental philosophies, a number of scholars well-versed in both Confucianist and Western philosophy expressed the view that since Western thinking had shortcomings, it should not be adopted without making changes to it. They founded a variety of modern Neo-Confucianism based on traditional philosophy integrated with suitable aspects of Western culture and philosophy.

Assimilating Bergson's philosophy of life, Liang Suming established his own Neo-Confucianism. His lectures on 'the Civilization of the Orient and Occident and their Philosophies' drew widespread attention. His variety of Neo-Confucianism stresses that the Chinese ideal of the 'mean' (the harmonizing of passions) contrasts markedly with Western and Indian philosophy. Xiong Shili founded the 'new doctrine of consciousness only'. In fact, his philosophy is a combination of Buddhist idealism, Wang Yangming's mentalism, and Bergson's theory. Many philosophical terms he used came either from *The Book of Changes* or the Buddhist 'consciousness only' school, while some of his basic philosophical concepts, such as 'the unity of substance and function' and 'the primacy of the original mind,' originated from the Neo-Confucianism of the Song and Ming dynasties. His philosophy avoids both Zhu Xi's dichotomy of the principle and material force as well as Wang Yangming's subordination of material force to the mind, thus injecting a view of dynamic change into Neo-Confucianism. Feng Youlan, who studied philosophy at Columbia University in New York, set up the new rationalistic Confucianism, which converts Confucianist philosophical concepts into formal logical ones. Merging Western realism and logic, Taoist negativism and transcendentalism, he claimed that the theoretic pillars of his philosophy are the four basic metaphysical categories: (1) 'Principle', which belongs in the realm of reality; (2) Material force, the basis of the concept of existence; (3) Tao, which is a universal operation and a regularly improving and changing universe; and (4) the Great Whole, where one is all and all is one and which constitutes the transcendent supreme reality. He Lin made outstanding contributions to the spread and study of Western philosophy, particularly Hegelianism, in China. Between the 1930s and 1940s, he put forward a program of Neo-Confucianism in which he stressed the necessity to reform traditional Confucianism by absorbing the positive elements of Western philosophy and culture so as to meet the modern challenge of reviving the national culture. He advanced the theory of subject as the 'logical mind', called for the integration of cognition, morality, and aesthetic sentiment into the logical subject, and the dynamic unification of knowing and practice.

The above-mentioned modern Neo-Confucianism displays the following three obvious theoretic characteristics: (1) it persists in the theory of holism and monism in traditional Chinese philosophy in an effort to counter dualism in Western and Buddhist philosophy; (2) it develops the intuitive cognition of traditional Chinese philosophy and stresses the importance of intuition and cognition; (3) it views human nature and life as part of a fluid and evolving reality, a flux. Therefore, the ethical codes and moral principles in traditional Confucianism should also be revised and adjusted to enable human beings to continuously improve their inner spiritual life to be prepared for the challenges from the outside world and modern social life.

In the latter half of the twentieth century, many Chinese philosophers have comprehensively and systematically studied traditional Chinese philosophy including Confucianism, Taoism, Buddhism and other schools of thought in accordance with Marxist views. Hou Wailu, who had largely contributed to the spread of Marxism in China with his translation of Marx's *Das Kapital*, published his five-volume work *The History of Chinese Ideas* (in collaboration with Du Guoyang), which is often praised as an outstanding application of Marxism to Chinese philosophy. The authors have judiciously selected the

essence of traditional philosophy. They have also concentrated on studies in two important areas. Firstly, they have studied the relationships between traditional Chinese philosophy and modernity in an effort to explore the best way to advance traditional Chinese philosophy, and to constructively integrate it into the modern socialist cultural system. Secondly, they have conducted comparative studies between traditional Chinese and foreign philosophy to explore the significance and value of Chinese philosophy from the broad perspective of world civilization.

## Japanese philosophy

Since 1914, Japanese philosophy has been developing in two different but intertwined directions. The first tendency came from the attitude espoused by Tokyo University, which very early attempted to ponder over questions in the context of the European experience. This school of thought was mainly represented by Tetsujiro Inoue. His successor, Genyoku Kuwaki, conducted numerous studies on Kant, and under his encouragement, Neo-Kantianism spread widely and exerted great influence during the rule of the Taisho regime (1912–26). In addition, Husserl's phenomenology was introduced in Japan as early as 1921. The second tendency was advocated by Kyoto University under the guidance of Nishida Kitaro (Plate 108). It attempted to develop a Japanese philosophy based on Japan's own experience rather than the European model. The Tokyo school thoroughly studied the philosophic thought of the European continent as its primary task, while the Kyoto school attempted to absorb European philosophy by referring to Japan's own historical experience. It is particularly worth noting that Nishida possessed a profound knowledge of Chinese culture particularly regarding pre-Qing Dynasty Confucianism, Zhuang Zi's thinking and Wang Yangming's doctrine. In a study of the good, Nishida strove for a 'logic of field'. The Oriental logic he created borrowed Wang Yangming's idea of the 'unity of knowing and doing' and the Confucianist doctrine of the 'Mean'. According to this logic, 'good' means not only the satisfaction of a certain need at a certain time, but also harmony between various activities. Nishida's theories merge oriental and occidental philosophies to form the structure of the 'Nishida philosophy'.

In addition to the two major philosophical schools mentioned above, there also existed the Kyoto School led by Hajime Tanabe. Tanabe was an outstanding expert in the philosophy of mathematics and science and renowned for his studies on 'logic of the species'. The species in question refers to the nation, which lies between individuals and humankind and connects the two. After the Second World War, Tanabe was the leader of a group of intellectuals who urged a thorough housecleaning of theories on ultra-nationalism. The second most active philosophical school after the war has been Marxist philosophy, introduced to Japan by Sen Katayama in 1903, and by Hajime Kawakami in 1922. The most active advocates of Marxism after the war were Kiyoshi Miki and Jun Tosaka. These Marxist thinkers had been the principal opponents of the tide of pre-war ultra-nationalism. But in the 10 years immediately after the war, the force of Marxist philosophy burgeoned through academic publications and conferences. The third major philosophical school is existentialism,

which explored all of the movement's proponents from Heidegger and Jaspers to Sartre and Gabriel Marcel. Its main representative, Goichi Miyake, is renowned for his studies on Heidegger. Pragmatism is the fourth active philosophical school to develop after the war, owing to the activities of the Association for the Study of American Philosophy, its prominent exponent being Seiji Ueda, a scholar of longstanding authority on Anglo-American thought in the early 1950s.

## Islamic philosophy

Islamic philosophy is actually the collective achievement of a number of peoples including Arabs, Berbers, and Indians. It developed with the rise of Islam, which endowed it with a highly coherent world view. Islamic philosophy took shape in the mid-eighth century and later witnessed rapid development and dissemination under the influence of Greek thinking. The numerous studies on Greek philosophy and culture by Arab scholars greatly influenced the European Renaissance. According to Islamic philosophy, the status of humankind must be enhanced by its infinite power of reason. Consequently humankind does not have to rely on any supernatural force to find salvation. Islamic philosophy recognizes the dual truth of reason and revelation and maintains that human beings live in both the spiritual and earthly spheres, and they may enjoy the right to secular life in accordance with the Koran. In the twentieth century, while influenced by Western philosophical and cultural traditions, Islamic philosophy has maintained its own theoretic integrity, stability and critical capability and played an important role in religious and social life.

Indian Muslim philosopher Muhammed Iqbal studied Western philosophy, especially the works of Hegel, Whitehead and Bergson, and reinterpreted Islamic philosophy using modern philosophical concepts. He considered religion the manifestation of human beings' integrity and a key component of the 'reality' on which the philosopher reflects. The concept of the concrete world embodied in the Koran refers to a created reality, characterized by a rational mode of integrating truth and idealization. However, the world is neither a stagnant universe nor the ultimate product of Allah, but rather a universe achieving continual self-realization in time and space. And human beings, as the most active force in the universe, serve as Allah's main agent in the process of realizing the infinite potential of 'reality'. Religious experience has extrinsic, intrinsic and mystic characteristics, thus enabling human beings to continuously reveal the complex facets of their own reality. Moreover, reality can be verified not only through experience but also by philosophical speculation. Iqbal incorporated some ideas from Western philosophy and science. He rejected the hypotheses of material reality and gave a new explanation to atomism by using the term *monadology* or *spiritual pluralism*. He believed that every molecule or element is spiritual and possesses an ego and that the higher the level of ego or consciousness the greater its reality and the closer it is to Allah. The spiritual ego, as an individual and eternal soul, is the core of the spiritual state or emotion, while a limited ego is only one aspect of the ultimate ego inherent in nature.

Like Iqbal, Muslim philosophers such as Al-Afghani, M. 'Abdu and Ameer Ali maintained Islamic views on life

despite the fact that they were influenced by Western philosophy. Sayyid Qutb, an Egyptian thinker and activist pointed out in *Islam and the Problems of Civilization* (1963) that the comprehensive Islamic way of life can save modern man. Muhammad Al-Bahi espoused even more radical views. In *Islamic Thought and its Relation to Western Imperialism*, he claimed that Western civilization has failed to solve contemporary problems primarily because of its misuse of the medieval scientific spirit in the fields of industry, technology, economy and biology. Egyptian philosopher Abbas Mahmud al-Aqqad took a relatively moderate attitude and criticized those rationalists who regard religious faith as superficial or illusory.

Other modern Arab thinkers, such as the Egyptian A. R. Badawi and the Lebanese René Habachi, are renowned for their studies on existentialism in the contemporary Arab world. In *Existential Time* (1941), and *Studies in Existential Philosophy* (1961), Badawi stresses that human beings must accept the brevity of life and must face their fate with the power of true freedom. Although Habachi rejected existentialist atheism and illusory individualistic philosophy, he nevertheless urged people to transcend their individual limitations and seek a reality on a higher level, which constitutes the existential experience of humankind. Egyptian philosopher Zaki Najib Mahmud, whose principal works include *Positivist Logic* (1957) and *Toward a Scientific Philosophy* (1958), devoted himself to expounding Western positivism.

Philosopher Yusuf Karam was a pioneer of modern systematic philosophy in the Arab world. In *Reason and Being* (1956) and *Physics and Metaphysics* (1959), published not long before his death in 1959, he maintained that both empiricism and rationalism are untenable and that only by consciously drawing on pagan ideas can Muslim and Christian philosophers developed a comprehensive world view. His philosophical methods were representative of the trend in contemporary Arab thought to attempt to reconcile various conflicting philosophical and theological thought.

## African philosophy

Since the beginning of the twentieth century, the African intelligentsia have been examining their own continent's philosophical traditions and debating such issues as 'Does an African philosophy exist? And if so, how can it be defined?' In their discussions, they have obtained an affirmative answer to the first question, but the debate on the second one is ongoing. Many African philosophers believe that a sufficiently sound literary philosophical tradition has existed in Africa since ancient times. This view has mainly been expounded by Lancinay Keita, who has divided African philosophical tradition into three stages: (1) classical philosophy, mainly ancient Egyptian philosophical thought, which had a strong impact on the Hellenic world before it influenced the Renaissance period in Europe; (2) medieval philosophy, mainly comprising African interpretations of Islamic thought and particularly active under the medieval African states of Ghana, Mali and Songhay; and (3) modern philosophy, which encompasses (a) the relatively undeveloped philosophy prevalant in Africa during the colonial period, which had significant political and literary components owing to Africa's colonial past and (b) post-colonial philosophy.

Keita described the main characteristics of African philosophy as follows: African thought is essentially holistic in the sense that it accepts the material world, thus making possible empirical science, yet at the same time it recognizes that metaphysical elements constitute the ontological support and motivational force for movement in the world. Another important specialist on African philosophy is H. Odera Oruka, who divided contemporary African philosophy into six schools of thought: (1) ethno-philosophy, which regards all ethnic African world views, myths, folklores and folk wisdom as African philosophy; (2) sagacity philosophy, which deals with the wisdom of certain respected African sages, whose thought and wisdom derived from their innate insight and reason rather than communal consensus (the main representative of this philosophy is Marcel Griaule); (3) nationalist-ideological philosophy, which holds that genuine and meaningful freedom is inevitably accompanied by a true ideological liberation and a return to traditional African humanism; this philosophy has been mainly advocated by Kwame Nkrumah, Julius Nyerere (Plate 109), and Leopold S. Senghor, whose philosophy of 'Négritude' was popular in the 1960s (according to this movement, reason is Hellenic while emotion is characteristic of the black people, and African thought, being intuitive, cannot be viewed in terms of the rational, the irrational or the pre-rational); (4) professional philosophy, which rejects the assumptions of ethno-philosophy and takes a universalistic view, arguing that true African philosophy is the domain of African professional philosophers; this tradition is critical and strict and does not consist simply of interpretations and descriptions of African traditions of thought (its main advocates are Kwasi Wiredu, Paulin Hountondji, Henry Oruka and Peter Odera Bodunrin); (5) hermeneutic philosophy, which conducts analyses of specific concepts by using existing African languages in an effort to clarify the general and logical meanings of these concepts (it is mainly represented by Kwami Gyekye, Barry Hallen and Olubi Sodipo); (6) artistic or literary philosophy as adopted by certain African writers such as Chinua Achebe, Wole Soyinka, and Ngugiwa Thiongo, among others. Although not a philosophy per se, it has been shaped by the profound philosophical thoughts expressed in the works of these literary figures.

## Latin American philosophy

Mainstream schools of philosophy in Latin America in the twentieth century have come into existence by way of opposition to the positivism of Auguste Comte and Herbert Spencer. Generally speaking, Comte influenced thinkers in Brazil, Mexico, and Chile, while Spencer's following developed mainly in Argentina, Uruguay and Cuba. Positivism claimed that its knowledge had been verified, was logically strict, and could be easily applied to actions and help solve existing social problems. The promises it held out were fairly attractive to the Latin American intelligentsia. Indeed, many people hoped to find solutions to the continent's serious social ills, particularly poverty, through this philosophy. However, reality did not measure up to positivism's promises and aspirations. When progress failed to materialize, Latin American intellectuals turned against positivism, beginning in Mexico. With the fall of

the dictatorship of Porfirio Diaz in 1911, positivism also fell. And its influence subsequently waned in other Latin American countries.

Then, Latin American philosophy turned to the works of Bergson, Croce, Nietzsche, and Schopenhauer, who had criticized the narrow scientific emphasis of positivism. Since then, the continent has seen four generations of philosophers. The first generation is that of the trail blazers: Antonio Caso and José Vasconcelos (Plate 110) in Mexico, Alejandro Korn in Argentina, Vaz Ferreira in Uruguay and Farias Brito in Brazil, which had remained under the influence of positivism for some time. These philosophers developed a new philosophical thought in Latin America by borrowing heavily from European philosophers including Husserl, Dilthey, Heidegger and Jaspers. Although they did not form an actual school of thought, they brought forth a new philosophical attitude and method. The second generation was mainly represented by Francisco Romero, who carried on the traditions of the older generation, but was freed from the controversy over positivism that had influenced the previous generation. Romero and his generation were preoccupied with the problems of man and greatly influenced by historicism, phenomenology, and existentialism. Most of the philosophers of the third generation, represented by García Maynez and Llambias de Acevedo, were born around 1910 and studied philosophy in German universities. As a result, they were more professional and their interest more wide-ranging, even though none of them had the intention of creating a new philosophical system. The fourth generation is larger in number and more active. Augusto Salazar Bony and Auturo Roig are the most prominent members of this generation and remain very active in the Latin American philosophical circles at present. They have maintained their interest in German philosophy and attach great importance to British and American philosophies, particularly new headway made in analytic philosophy. Inspired by the enthusiasm of Mario Bunge, the current generation has conducted studies on the philosophy of science in collaboration with many professional scientists. Marxist philosophy has also been studied and spread on the continent. At present, Latin American philosophy is taking root in the cultures of various nations and is expected to produce more fruitful results.

## CRITICAL ISSUES IN CONTEMPORARY PHILOSOPHIES

In the process of diversification, contemporary philosophies have raised issues of universal significance regarding world peace, development and the future of philosophy and human civilization.

### Objectives and mission of philosophy

Most of the principal contemporary philosophical schools have criticized traditional philosophy for studying basic problems. However, they differ greatly over the interpretation of philosophy's meaning, subject matter and research methods. In the transformation of science and social life, contemporary philosophies study and explain man and reality from different perspectives. Philosophies based on materialism or scientific realism, which endeavour to integrate knowledge systems and to depict a general picture of the world, have reached an unprecedented breadth and depth in their exploration of the order of the macro-universe, microworld properties and the relationships between body and mind. Humanistic philosophies explain the world created by humankind and its culture in exploring self-consciousness and historical existence. Post-analytic philosophy has begun to take a new approach towards the study of the once-rejected metaphysics, which explains the relationship between language and reality in terms of integral experience or conceptual frameworks. Proponents of this school are therefore seeking new ways of 'philosophizing', and the 'way of philosophizing' itself has become a subject of great interest. Analytic philosophy along with other philosophies developed by Europeans stress the prominent role of language.

The linguistic ontology of current analytic philosophy undertakes in-depth studies on topics such as being, reality, truth, nature and structure of mind, while European continental philosophy regards language as the basic means of critically examining the meaning and value of modern society, culture and life.

Various contemporary philosophies have greatly contrasting objectives. Analytic philosophy views philosophy as an activity for diagnosing and treating linguistic and conceptual ambiguities and seeks accuracy of knowledge and scientific rationality. Some humanistic philosophies aim at describing the transcendental structure of consciousness, explaining the truth and value of life, fostering a mechanism for the healthy development of man and culture and overcoming the crisis of alienation in modern society. Stressing a scientific worldview, Marxism not only explains the world but also transforms its guiding practice so as to enable human beings to attain freedom from the realm of necessity, thus realizing the social ideal of humankind's overall development. However, despite their different theoretic orientations, contemporary philosophies have been pondering their common mission. Confronted with challenges to civilization and progress posed by the nuclear threat and ecological crisis, injustice and inequality, disparity between rich and poor, ethnic and regional conflicts, cultural contradictions and moral confusion, philosophy should provide new meanings and wisdom to the diversified development of culture and society and the establishment of a reasonable world order based on mutual cooperation. Philosophy must also attempt to examine and solve major problems emerging in scientific, cultural and social processes and to suggest viable guidelines for values and criteria regarding means to attain the good. Philosophy today, 'as the owl of Minerva spreading her wings with the coming of the dusk' of the twentieth century, should not only review its past journey, but also use its historical insight to examine the various contradictions to be faced at the beginning of the new millennium of civilization and to conceive an ideal that accurately reflects human nature.

### Scientific reason and humanistic consciousness

Theories of knowledge and methodology occupy a special place in contemporary philosophy. Philosophy cannot only contribute to the enhancement of rapidly evolving contemporary knowledge, but can also enable knowledge to

play an effective role in cultural and social development. Philosophical studies on knowledge and method in the past century have demonstrated the divergence of scientism and humanism. Scientism places great value on analytic reason and applies the methods of natural sciences as paradigms when studying all branches of knowledge. It attaches importance to studies on the truth of facts or events by using precise linguistic and logical analysis, stresses the usefulness and essential role of knowledge in social development and believes that rationalization of the social order and industrial civilization can be achieved mainly by involving human intellect. Humanism, on the other hand, maintains that all knowledge results from humankind's cultural creation and cultural foundations and that development should be explored by describing and interpreting the constructive acts of man's inner consciousness, and that all cultures, including scientific knowledge, are rooted in human existence and the concrete world. Therefore, humanism stresses the social functions of cultural values and criticizes the varieties of social ills resulting from undue emphasis on reason in technological civilization.

Scientific reason and humanistic consciousness are also embodied in the theories and methodologies of the natural sciences and socio-humanities, respectively. The former stresses intellectual, logical analysis and proof, while the latter focuses on the understanding and interpretation of socio-cultural phenomena. Scientism and humanism have both significantly enhanced our knowledge by using their specific methods, but they are also exploring some more far-reaching subjects that involve interlinking scientific reason and humanistic consciousness. The development of contemporary knowledge is characterized by a high degree of specialization and blending of disciplines and the interpenetration of knowledge from the natural and social sciences. This also requires the integration of scientific reason and humanistic consciousness, thus enabling various branches of knowledge to interpenetrate and complement one another. For example, contemporary philosophies have been paying more attention to bringing the development and application of science and technology into the orbit of rational cultural values in an effort to avoid the misuse of these and to ensure sustainable development and security for humankind. The rapid development of ecological ethics and bio-ethics in the past 30 years illustrates this point.

## Philosophical understanding of human beings

Human beings are another important subject of study for contemporary philosophers. However, great differences in the understanding of human nature and the meaning of human existence must be noted. Marxism holds that human essence is the summation of social relations and calls for the emancipation of mankind's essential power by eliminating *alienated labour*, namely enslavement resulting from irrational social relations. Analytic philosophy usually considers human nature through studies on the experience of linguistic behaviour and the mind. Others explain human nature in terms of irrational emotion, volition, or instinctive passion. Some contemporary humanists highlight the central position of man as subject, probe into the self-consciousness of transcendental or practical subjects, and endow human nature with attributes different from those advanced by traditional humanism. Moreover, they

criticize the fact that the Enlightenment considered abstract reason as the eternal human quality. Heidegger vehemently attacked the notion of an abstract human nature and stressed the temporal, historical and mortal nature of human existence. The structuralist attitude of anti-humanism actually denies the central position of subject in cultural shortcomings, even though it derived from European humanism. The historical image of the human being has diverse facets and has changed constantly. Therefore, it is inevitable that differences in philosophers' conceptions of human beings will persist. However, humankind must free itself of various kinds of bondages and suffering and achieve healthy development in order to fulfil its potential and build a place in the real world.

Truth and value are one of the same whole. In exploring truth, we also seek value, which constitutes a crucial issue in understanding human beings and their activities. Because of differences in national conditions, traditions and social systems, various societies have divergent value systems, and it is impossible to make all of them obey a single foreign value system. Contemporary philosophers have increased their exploration of axiology. Starting from their own philosophical principles and socio-cultural backgrounds, they naturally hold different positions on basic values such as the good, justice, equality, liberty and responsibility, right and obligation, fairness and efficiency, and on the criteria for choosing values. In view of the changes and contradictions in social life and in order to reform or improve the social system and moral life, contemporary philosophers attach importance to reflecting on ways of adjusting existing value systems. In his influential book entitled *A Theory of Justice* (1971), American philosopher John Bordley Rawls criticized the utilitarian value system prevailing in some industrialized countries and the ills it has generated. He maintains that a just society with a sound moral value system should be established according to the principle of equitable justice chosen by rational man, where individual freedom would exist alongside social cooperation and a relatively equal distribution of wealth and rights.

In their studies on human beings, contemporary philosophies have highlighted two other subjects of practical significance:

- *Human beings and social development.* The once-prevalent theory according to which development is merely a function of the linear growth of economic quantity and material consumption has met with criticism because it has led to social inequalities. The new visions of development perceive the human being as the goal of development and stress the need to achieve the overall physical and mental development of human beings within comprehensive social progress. This entails recognizing the crucial role of cultural value. Committed to this goal, UNESCO has since the 1970s contributed greatly to promoting studies on the role of culture in social development.
- *Man and the environment.* The ecological crisis that emerged in the industrialized world has prompted contemporary philosophers to once again reflect upon the relationship between humankind and nature. Rejecting the idea that the rational power of human beings is reflected in the conquest of nature, today's thinkers point out that if human beings, driven purely by practical considerations, excessively exploit Earth's natural resources, they will seriously jeopardize their

own existence and development. From the 1920s to 1940s, V. I. Vernadsky in Russia and Pierre Teilhard de Chardin in France formulated the theory of *noosphere*, which emphasizes that human reason, environment and universe constitute an organic and living unity and that society and nature, humankind and the biosphere should evolve in a coordinated and interconnected manner. This doctrine has fostered studies on the philosophy of environmental protection. Although they differ in theoretic orientation, contemporary philosophies generally claim that harmony between human beings and the natural environment should be guided by values compatible with the interests of the whole of humankind and that people should shoulder moral responsibilities with regard to the environment and ecology in order to ensure the survival of humankind and social development for future generations (Plate 111).

### Philosophical and cultural traditions and their communication

Philosophy as the theoretic core of cultural traditions is not divorced from history. The founding of a number of schools of philosophy in the twentieth century reflected a critical attitude towards traditions. Certain contemporary philosophies tend to reflect on traditions in a constructive manner, since they recognize their vitality and support the renewal of traditions in an evolving process. According to the theory of virtue elaborated by American philosopher Alasdair MacIntyre, in order to overcome the crises of moral relativism and scepticism in modern society, it is necessary to construct traditions to carry forward the essence of the Aristotelian tradition and to probe into the issue of 'rationality of modern practice' in an effort to reconstruct individual and social virtues. Philosophical circles in various countries, particularly developing ones, tend to emphasize studies on indigenous philosophical and cultural traditions. Increasingly, philosophers are of the opinion that traditions do not necessarily constitute roadblocks to historical progress and that those vital contents can take on new meanings and play a positive role in social development today. For instance, contrary to the individualistic value system dominating some Western industrialized countries, the collectivist value systems and other rational contents implied in the philosophical and cultural traditions of some East Asian countries are related to these countries' successful socio-economic development. This subject has attracted widespread attention in scholarly circles.

In the world today, global communication is increasing daily, and exchanges between various philosophical and cultural traditions have reached an unprecedented magnitude. Contemporary philosophers are concerned with understanding and dealing with such exchanges so as to benefit indigenous socio-cultural development and world peace and culture. Related studies have contributed to creating a growing consensus on a number of principles:

– *Respecting the diversity of national philosophical and cultural traditions*: Because of differences in historical conditions, nations naturally possess distinct traditions. Each nation should therefore understand and respect other traditions and acknowledge their important role in maintaining the identity of national culture.

– *Realizing complementarity between various philosophical and cultural traditions*: Indigenous traditions might be enriched by absorbing the outstanding achievements of foreign philosophies and cultures in the light of their local contexts. However, such assimilation must not be mechanical and rigid, because it could result in social upheaval, stagnancy or the disintegration of indigenous cultures. Contemporary philosophers value comparative studies on various philosophical traditions, which enable them to learn from each other's strong points and offset their respective weaknesses.

– *Promoting dialogue between different philosophical and cultural traditions to seek common points while preserving and respecting differences in an effort to safeguard world peace and development*: The world today faces the challenge of multiculturalism, and if not dealt with properly, collisions between different cultures, which could become a pretext for local ethnic or regional conflicts. The claim that in today's post-Cold War world clashes between different civilizations are inevitable and will dominate the global politics is simply untenable. As long as the cultures of the world communicate in a spirit of equality and mutual understanding and well-being, they can undoubtedly make new contributions to world peace and human civilization.

## RELIGIOUS TRADITIONS

*Jean Lambert*

### THE COMPARATIVE STUDY OF RELIGIONS

Some twentieth-century thinkers have suggested that religions function like languages, and there is no other way of speaking than naturally. Faced with this irreducible plurality of 'religious languages', our only recourse is translation, since there is no single language that predominates. There are only 'regional accents' and 'new dialects' that appear or disappear, and in which the word *god* does not necessarily figure. 'Hinduism', for example, is an English invention of 1830; 'Confucianism' is a concept that does not exist in Chinese; in the Arabic language, the word *jihad* conveys the idea of endeavour or striving; and Buddhism is unaware of the self. These different variations on a theme gave rise to the twentieth-century idea for the study of comparative religion.

The comparative method is the only experimental approach that is able to shed light on the historical and anthropological study of religion. The history of religions is not a field of knowledge in itself.[1] Religious history, which was originally confessional in approach or took the form of apologetics, has given way to a more neutral kind of history. This secularization of the study of religions derives from the crisis of dissent within the institutions themselves, leading historians to seek the roots of these divergences and wonder at their meaning.

There are several currents of thought. *The sociology of religions* observes the actual dynamic of the break-up and re-forming of religious phenomena in the modern world.[2] *Ethnology*, working alongside a history of religions uncoupled from the evolutionist hypothesis, determines the specific function of religions within a particular social context. The semiotics of mythological narratives, rituals and pantheons covering broad linguistic areas helps to identify the fundamental ideological configurations that each society reinterprets for itself. Religious history correlates deviant forms and marginal religious attitudes with the social structures of particular periods. It is only over an extended period of time that it becomes possible to create links between the long-forgotten rituals that ethno-history brings to light, and the seemingly random proliferations that

today's sociologists have described. Modernity is in no way a 'revival' of religion, but by enabling us to gain a better retrospective grasp of what the past concealed, it sheds light on the vigorous nature of the religious element that social groups seems to require.

This rich deployment of the social sciences to illuminate religious phenomena owes much to the development of comparative anthropology, especially the anthropology of myths, which are useful for demonstrating how religions are organized according to a coherent architectural structure, and how the changes affecting them obey specific transformational rules. The French scholar Georges Dumézil took the decisive step in the comparatist direction by linking the comparative philology of Antoine Meillet and Emile Benveniste with the historic sociology of Marcel Mauss and Marcel Granet. Meticulous collaboration between the two disciplines made it possible to bring together the different religious systems of the Indo-European peoples in one and the same area of study, in which the ideological fields, despite their significant divergences, show structural analogies based on functional relations. The comparative method as a general approach to studying religion was officially recognized in 1935 at the Ecole Pratique des Hautes Etudes in Paris. The tripartite functional model has intellectual significance. Concordance between one religious system and another is not only linguistic or theological, nor does it concern only rituals and myths; it also determines the order of discourse. The comparatist seeks out the thought structures of this ideology by following the transformations and transpositions of a single model through all its historical variations. Dumézil turns a religious corpus into an objective, transcultural universe that must be studied in itself, without being reduced to an order of realities external to it, such as affective urges, ritual practices, historical facts, social structures or experience of the absolute. The religious phenomenon in its structural invariance, reconsidered from a broad comparatist angle, can be a powerful instrument for interpreting the unforeseeable variations of societies, on the basis of that which unites them.

By complementing structural analysis with study of the social and historical context in which myths emerge, we can arrive at a more precise knowledge of the diachronic

processes affecting traditional societies, while a broad post-structural analysis of the traditional religions of historical societies can give us a more systematic grasp of the coherence of their religions. It is by combining these two approaches that we achieve a broadly comparative science of religions capable of treating all religions on an equal basis while respecting their differences. If, someday, the world religions seem likely to make peace among themselves, it will be partly due to this intellectual effort: respect for others is not a conciliatory gesture reluctantly conceded, but must be sought after and recognized as a fundamental principle.

## MAIN TRENDS IN RELIGION

### Islamic fundamentalism

Fundamentalism is not specific to Islam. It is also present in Catholicism, Protestantism, Judaism and Buddhism. The 1970s and 1980s saw a general rise in the power of Islamism in the Muslim countries, as witnessed by the Pakistan National Alliance's religious agenda in Pakistan in 1977, the Islamic revolution in Iran in 1979 (Plate 112), the assassination of President Anwar El-Sadat in Egypt in 1981, and the fragmentation of Lebanon under pressure from the Hezbollah and the Islamic Jihad. Everywhere, from Sudan to Indonesia, Islam seemed to be diverted towards political ends, right up to the frustrated victory of the Front Islamique du Salut in Algeria in 1990, and the armed struggle in Egypt against the Mubarak regime. The challenges of modernity to Islam – the advancement of education and science, the development of independent reasoning, the desire for independence and political participation – were aggravated by the fact that most Muslim countries had been colonized by a Western, self-styled 'humanist' culture that many considered an affront to their dignity; often it coincided with people's nostalgia for earlier days of glory and power. At the same time, and despite their regained independence, these states that are muzzled by strong regimes and subjugated by world markets have not lived up to the peoples' expectations. People no longer tolerate the idea – current from the 1950s to 1970 – of the superiority of the Western model of development, especially since their political authorities have sometimes demonstrated their ineptitude for democracy.

The rise of different forms of Islamism is based on certain internal reform movements that emerged in modern times. The Muslim Brotherhood, which was founded in Egypt in 1929, seeks a complete return to the basic principles of Islam. Led by a supreme guide and systematically positioned in urban neighbourhoods, the Brotherhood devotes itself to the literal interpretation of the Koran, advocates the application of *shari'a* law, which alone is regarded as capable of solving problems of both individuals and society, and rejects any foreign 'contamination' of Islam. Spreading rapidly beyond the boundaries of Egypt, in forms ranging from pietism to extreme radicalism and terrorism, it has moved away from its reformist base and urged the humiliated *umma*, the community of believers, to put their trust only in Islamic law.

The Tabligh movement, founded in India and subsequently known under the name of Faith and Works, trains teams of missionaries who reject violence and work among the immigrant populations. During the social and

national protest against the brutal, secular modernization of the country, Iranian Shi'ism found a crucible from which emerged the clerical power that was to revolutionize the Shi'ite tradition itself. The Ayatollah Khomeini, exercising both religious and secular powers, revitalized a Muslim community both inside Iran and abroad; he drew upon the great Islamic principles to combat a demonized West, using military and other means. Saudi Arabia, officially custodian of Islam's holy places, has long financed Muslim communities in Arab countries, and immigrant Muslim populations through the World Islamic League, but its leadership was jeopardized by the rise of Iran and its 'betrayal' during the Gulf War of 1990. Saudi Arabia's subsequent eclipse has hastened the radicalization of Islam and the destabilization of the more moderate regimes, while Sudan, ravaged by civil war and famine, has invoked Islamic law against animist and Christian minorities. The revival of Islamism therefore took place in three phases. The rise of Iranian Shi'ism at the end of the 1970s, a populist uprising against an enemy demonized by an intransigent Islam, marked the rise to power of a political form of Islam that sought to use that power to establish an Islamic society. Pakistan, Afghanistan, Egypt, Syria and far-away Indonesia also adopted Islam as an instrument of resistance and opposition movements, while the established leaders in Libya, Sudan, Saudi Arabia and Morocco sought to use the name of Islam to legitimize their power and policies.

The success of this form of Islamism depends, however, on an unlikely alliance between intellectuals, young militants, the clergy and the common people. But it did achieve results throughout the Muslim world, including among immigrant populations, by building up a network of associations, by organizing religious activities centred on the mosques and by community development. Infiltrating civil society in order to occupy positions of influence and introducing a moral dimension into educational and social activities, this second phase found expression in the Algerian Front Islamique du Salut, including the latter's participation in the electoral process until it was halted by the authorities in 1992, thus leading to radicalization and bloodshed. Based on Islamic awareness-raising at the grass roots, this second form is as undemocratic as the first. Its relative lack of success has led to the established regimes being challenged by armed violence, whether ongoing as in Algeria or sporadic as in Egypt, or in Palestine with the Hamas, in an alternating process of provocation and clampdown in which Islamism, now armed, is a cause of concern to neighbouring countries.

Islam thus finds itself reduced through its own internal tensions to an ideology of social liberation and political conquest, underpinned by strict religious observance, and an Islamic organization of society, fragmented by revolutionary guerrilla movements, which divide it internally in direct opposition to its deepest objectives, that is unable to offer anything but a puritanical neo-conservatism, as restrictive as it is disappointing.

### The Vatican's efforts to prevent the decline of Catholicism

The Catholicism of the Pope serves as a worldwide paradigm of religion's crisis at the end of the twentieth century. The previous century witnessed the loss of the Pope's temporal

power, and the twentieth century may confirm the loss of his spiritual power,[3] for the Pope's strategy has been to counteract the dismantling of the institutional structure of belief. John Paul II's pontificate went through two phases. Until 1989, he was the Pope of human rights, the standard-bearer of emergence from communism and the establishment of political democracy. It was thanks to him that, in Poland, the three components of the *Solidarnosc* resistance movement – workers, intellectuals and the Church – came together, a pattern repeated throughout Eastern Europe. There is considerable ambiguity about the content of these 'human rights', but religious freedom, which was unacceptable to the communist authorities, created a semblance of consensus.

However, John Paul II was increasingly disconcerted. The societies that were supposed to undergo evangelical renewal soon displayed the same shortcomings as their Western counterparts. For John Paul II, the victory of the Church over atheistic communism represented the victory of religion over the modernity that had spawned communism. The new evangelism he expressed in *Crossing the Threshold of Hope* (1994) claims that, for three centuries, life and thought in the West was largely dominated by the combat waged against God, and that Marxist collectivism is only an 'aggravated version' of that programme to eradicate Christianity. The encyclicals *Centesimus annus* (May Day 1991) and *Veritatis splendour* (1993) deplore this perverse project of building a world without God, one which relativism aids and abets by obscuring the sense of a strong moral anchor. The encyclical *Evangelium vitae* (1995) is a sombre denunciation of 'the culture of death', with apocalyptic overtones.

After 1989, public debate in Poland turned to such questions as abortion, divorce and religious instruction in schools, with the Concordat between the Roman Catholic Church and the secular government enabling society to construct its own democratic pluralism. It was no longer thanks to the Church, but rather despite its opposition, that Poland moved towards democracy. The Pope did not denounce democracy, but continued to inveigh against a modern world released from the Church's grip. Freed from a system whereby meaning is collectively organized and imposed on the individual, post-communist society, and perhaps other societies still more, became receptive to the ideas of pluralism and relativism brought to the fore by globalization. The spiritual power of the Church saw this as a negation of the universal. Its project for a *universal* catechism that would offer a comprehensive account of Roman Catholic teaching came up against the expansion of the world, against individualization, rationalization and differentiation, as it did in the sixteenth century. Catholicism thus refused to accept that it was merely one option among a whole range of beliefs that may coexist in a democracy.

In the course of his many travels throughout the world, John Paul II countered this trend by reaffirming universalism, the maintenance of standards and continuity, unable to grasp that all the tragedies of the twentieth century had been tied to regimes professing a monopoly on truth. This blind spot accounts for ensuing profound disagreement over the link between ethical relativism, values and democracy. Democracy, however, is firmly situated outside the realm of values. It does not claim to arbitrate between good and evil, but endeavours only to provide a space within which such arbitration may take place and to define its

rules. Democracy is not the same thing as relativism and does not regard all opinions as being of equal worth. It makes the expression of all opinions possible and legitimate, and refrains from prohibiting any of them, provided they are expressed within the forum it creates and of which it is the guarantor. Any system setting itself up as an arbiter of the truth from which its legitimacy derives is one that rejects democracy: taken to its logical conclusion, this path would mean subordinating civil law to moral law and replacing democratic legitimacy by that of a Christian state, in which the Church ensures that the state's actions are in conformity with the truth and in which the place of non-Christians becomes problematic.

In 1995 alone, the 75-year old Pope John Paul II visited all five continents, attending everything from the gigantic world youth festival that brought three million people to Manila, to meetings in Sri Lanka to try to settle misunderstandings over Buddhism, which the Church considered an atheistic and negative doctrine of salvation, and the difficult dialogue with dissident Catholics in China. After his journey, the Pope altered his approach, shifting from open proselytism to a focus on ethics, which he believed would offer a unifying force that could transcend cultural differences. He surprised the United Nations – then celebrating its fiftieth anniversary – by proposing a 'Bill of Rights of Nations,' or a 'Charter of Nations,' to clearly identify the rights and duties of all the nations of the world, in order to contain aggressive nationalisms and to promote the right to freedom of the peoples of the world.

## The emergence of ecumenism

The Christian ecumenical movement was born in 1948, merging two streams of thought. One represented the more theologically inclined Faith and Order movement, whose primary goal was to bring together representative people from different Christian confessions to work towards the visible unity of the Church.

The other, the more pastoral Life and Work movement, was an attempt by Protestant and Orthodox churches to reach consensus on the churches' universal practical role in society and to relieve human suffering. These two currents, bound together by their dependence on mutual understanding, were joined by a third, the International Missionary Council, which proposed itself as a middle way between the abstract and the practical. This three-way collaboration has so far managed to surmount its various crises. In 1961, at New Delhi, the International Missionary Council came together with the Orthodox Church and the Moscow Patriarchate to form the World Council of Churches (WCC). However, because of its involvement in the refugee question at the end of the war, the ecumenical movement was seen by some as too political, whereas Roman Catholicism, which took unity for granted, accorded priority to communion in faith rather than to charity, thereby opening a Secretariat for Promoting Christian Unity at Vatican Council II. There are thus two Christian ecumenical movements: the Geneva-based WCC (in competition with the fundamentalist, Amsterdam-based International Council of Christian Churches) and the Rome-based movement.

The Life and Work faction within the ecumenical movement, with its concern for refugees, its sense of guilt

for Christian anti-Semitism and its concern for the churches of Eastern Europe, was based on the *Universal Declaration of Human Rights*. The upheavals of May 1968 brought with them an increase in the influence of the Third World and young people, who demanded more attention to issues of freedom, revolution, imperialism and racism. Responding to their concerns the WCC became politicized and took a leftward swing. With the churches in Asia and Africa gaining autonomy, a political and ecclesiastical 'Third-Worldism' voiced the need to become more nationalist in character. Yet at the same time, criticism of the Soviet regime was tempered by considerations of *Realpolitik* and the desire to avoid harming the churches that were collaborating with the Communist parties.

In the 1970s three issues came to the fore: the anti-apartheid struggle which, together with support for Asia, absorbed a third of the WCC budget; support for liberation theology groups in Latin America; and the role of women – first as a political question of representation, then as a societal one of participation. The women's issue eventually eclipsed that of the Third World struggle and, together with the youth question, became the overriding concern.

After 1989 and the collapse of the Soviet Union, a veritable 'new left' in the WCC became interested in a number of utopian and pacifist social ideas that could cool national ardour, ecological ideas of respect for nature, and feminist ideas about achieving a better balance between the sexes. These concerns, which originated in Germany and the United States, aroused little interest in the South, where human rights was a burning issue.

The third movement attempted unsuccessfully to achieve a synthesis between political commitment and doctrinal unity on the missionary question. It no longer focused on destabilizing the churches, but sought to establish a dialogue with the other religions by focusing on divine action and showing respect towards newly gained national independence. In the late 1970s, some wondered whether Christology should be abandoned in favour of the pluralism seen in political democracy, but they met resistance over the perceived status of other religions, including resistance in the form of Karl Barth's view of the 'theology of religions' as a human quest. Islam was an additional problem because it seemed pre-modern, slower to develop than Christianity and even resistant to modernizing.

For twenty years, those who advocated dialogue were out of favour. They attempted to show there was a valid alternative to the missionary approach, but first had to settle what was essentially an intra-Christian conflict. Consequently they had problems both with Faith and Order, which warned against the danger of religious syncretism, and with the political left over the recognition of other religions: what, for example, was to be done about the caste question in the dialogue with Hindus, or women's equality in the dialogue with Islam? For the left, there could be no preconditions for human rights.

The question of human rights and Islam may serve as an example here. The universal principles of human rights are derived from secular humanism and are often in direct conflict with certain cultural traditions. While they may be of concern to a Muslim, they do not derive from divine revelation and God's law. The believer regards them more as duties, with which human beings must comply, rather than as rights to be established for them. They also clash with the definition of the rights of individuals by virtue of people's membership in a community, as in the *affaire du foulard* – the controversy set off in France in 1989, over a state school's refusal to allow Muslim girls to wear the traditional *chador* or *hijâb* headscarf to school.

The goal today is to create a common ground for dialogue; but while progress has been made in bilateral ecumenism, multilateral dialogue has run out of steam due to the proliferation of new religious movements. Some hundred international inter-faith organizations have emerged, bringing sectarian movements together in various 'fronts' and creating a flourishing industry, in some cases concerned only with the environment. The WCC has consequently proposed a new ecumenical discourse: ecumenism is not about churches, but represents a quest for human unity, like a service to be rendered to humankind. It therefore cannot continue as a para-federal organization of churches, but must become a network of energizing agents and revival movements.

The Christian churches have modelled their organization on the world of politics, if not actually on business and the multinationals, whereas it is civil society, with its prescriptive power with regard to the state that needs rebuilding. This involves putting politics in its proper place and re-creating civil associations, as attempted by a new humanitarian movement, which is highly interventionist in respect of the state's legislative authority; or by feminist activism – allied with the gay rights movement – denouncing violence and hostile messages. With Christianity in a stable situation, indeed with Pentecostalism gaining ground, Orthodox churches tripling their numbers, and with Islam also expanding, the WCC seeks to be a forum for testing the ideas of the future. It no longer talks in terms of mobilization, and its future would seem to lie more in serving as a fallback organization – for rich Protestants perhaps – one which has the advantage of being there in the absence of any alternative, playing much the same role as the United Nations does for the United States.

Since the Second Vatican Ecumenical Council (Vatican II, 1962–65), the Catholic Church has resolved to maintain an ongoing dialogue with the WCC. The ecumenical project has expanded to include a dialogue between Christians and atheists, and subsequently into intra-faith dialogues, as at the Organization of the Islamic Conference (1969) or the Buddhist Council (1984); almost all the world's religious leaders came together to pray for peace at Assisi in 1986.

For Protestants and the Orthodox, as for Catholics, the current movement towards unity means total reintegration in a world undergoing total transformation. Such social changes were previously supposed to produce only sects, which reflect the effort on the part of an entire community to achieve reintegration. Ecumenism might now be understood as total reintegration, even in its non-Christian, inter-faith forms, which are trying to steer clear of the difficult course set by the policy of maintaining a common front against atheism.

A non-religious *ecumenology* provides for typologies of more universal value than those offered by theology, and it can open up other possible routes for examining the dialogue with atheism in a non-denominational perspective. A general ecumenology would make it possible to rethink some of the essential areas of religious studies. It would examine the overall problem of inter- and intra-faith relations in space and time – that is, the relations of all

religious bodies with one another, whether or not they belong to larger groupings, and how the different tendencies within each religious body relate to one another and to those within other denominations. Those denominations which refuse such an ecumenology have their own conception of what constitutes a desirable ecumenicity, sometimes in the ideological form of the 'cloud of witnesses' – mythic links in a chain between believers from different times and different places.

Many sects, the Quakers for example, have set themselves the task of reconstituting lost unity, but their thinking is as much utopian as pragmatic. Whether religious, para-religious or anti-religious, as in the case of secular ecumenism, which regards religions as an obstacle to the unity of the human race, the most diverse schools of thought and many new religions are forms – secularized or otherwise – of an ecumenical project that has sometimes been in gestation for centuries. Both ideologies and institutions have their place in this, and not only official institutions, but also congresses, symposia and the countless groups in which internal and external dissidents gather, producing new official, semi-official or clandestine liturgies, and the types of authority which preside over religious divisions or encounters. Such ecumenism is also the source of new relations between religions and non-religion.

We now see how comparatism, which was originally historical and rather textual, ethnological and rather anthropological, opens up at the point where the observation of lineages of belief and structural transformations intersect, a wide field for an ecumenology aiming to modify our perception of religious phenomena. UNESCO's own concern that religious developments should be included in the present cultural history of humanity is itself an example of ecumenology.

## The emergence of neo-Confucianism

Since it merges imperceptibly with traditional Chinese culture, and has no fixed beliefs or social structures other than those that society generates for itself, it is even debatable whether Confucianism should be considered a religion. The last observance of the sacrifice to Heaven, the most important ritual of the Imperial Cult in China dating from about 1300 to 1111 BC dates back to 1945; since then Confucianism has become a private affair without legal authority. Most families nevertheless remain attached to ancestor worship, to the cult of the dead and even to the worship of a household god, and also to observance of the traditional festivals (Lunar New Year, the Lanterns and Dragon Boat Festivals, the Seventh Eve, and the Mid-Autumn Festival) that continue to provide a cosmological framework for social life. The neo-Confucianism of the 1950s, whose aim was to reconcile scientific and democratic modernity with the values of Chinese tradition, was a rebirth of the religion and became established in Hong Kong where it has flourished.

Neo-Confucianism has gained new credibility because so many Chinese-influenced countries (Japan, Taiwan, South Korea, Hong Kong and Singapore) have successfully achieved modernization without sweeping away their traditions. They prove the point that modernization does not necessarily entail Westernization (Plate 113). China has seen a positive re-evaluation of Confucianism since the

1980s, detached from the observance of liturgical obligations, which are left optional, but holding fast to reverence for spiritual and moral values. Confucianism lobs back into the Western court Max Weber's ill-informed opinion that without transcendence moral action lacks a powerful lever. The neo-Confucianists, who are admirers of Kant, believe that precisely because it is free from theology (and therefore provides proof against rational criticisms), their meta-ethics might offer a source of a spirituality that respects human rights and a particular form of democracy, against the background of a natural, conservative social hierarchy. As a religion of humanist culture and a philosophical doctrine of saintliness, neo-Confucianism may contain the seeds of a new China and South-East Asia, and, more broadly, hope for a new, non-Western humanism.

## The proliferation of sectarian movements

'Sectarian' movements are movements that owe allegiance to a leader or a doctrine. It might be argued that a major church is perhaps no more than a sect that has made the grade and continues to produce sectarian offshoots. Since the Second World War, for example, Protestantism in the English-speaking world has provided fertile ground for sects particularly inclined towards proselytizing; but what is new is the worldwide proliferation of sects (180,000 in Japan alone), the current success in the West of these groups since the failure of the protest movements of May 1968, their Oriental sources of inspiration and their transit via the United States. The first sects issuing from within Protestantism recruited adult females from relatively deprived social backgrounds. The new sects recruit young people from the educated middle classes, exhibit extreme anti-intellectualism, as in the case of Scientology or Transcendental Meditation, and lay great emphasis on affectivity. They generally profess a total rejection of politics, while developing, as in the case of the Children of God or the 'Moonies' (the followers of Sun Myung Moon and his Unification Church), a specific vision of history or salvation.

Such sects, or cults, have in common the practice of meditation under the authority of a leader to attain 'spiritual' power, since they place individual self-improvement, ideological conversion and transformation of behaviour above collective action in the world. They may sometimes aspire towards the union of religions and peoples, but this is not so much a matter of ecumenism as of proselytism, their communal lifestyles being intended to demonstrate solutions to human problems but with no direct connection to the outside world. The pyramidal organization of these sects, with the mass of the membership cut off from the leaders, and the followers' wills subordinated to a totalitarian organization, provides a regulatory framework not so much for a life of asceticism as for one of uninterrupted activity and work; this work is done for the exclusive benefit of the sect. Under cover of restoring authenticity, sects are often run as very well-structured businesses, exploiting the credulity of their members. In almost every case, they manipulate minds in a manner contrary to human rights, or may even themselves be connected with dangerous criminal enterprises.

For example, the Japanese Aum Shinrikyo sect carried out a gas attack in the Tokyo underground in 1965, killing ten people and poisoning 5,000. What becomes of an

apocalyptic religious message in an affluent society when fear, disease and poverty are not sufficiently distressing to provide the normal intake of recruits? The sect calls for the reconstruction of this world, but only after the world it denounces as evil has first been destroyed by criminal acts. This same argument was used by the Solar Temple Organization to lead a number of its Franco-Swiss disciples into collective 'suicide' in the Vercors area of France, and in Canada.

The International Society for Krishna Consciousness, founded in the United States in 1966 to propagate a lifestyle based on Vedic principles, has had to dismiss several of its leaders. It has a worldwide presence and its followers lead austere lives, reciting the great prayer (*mahānantra*) 1,728 times a day, and obeying a spiritual master in the belief that the Vedic model of society can lead to spiritual progress for all.

Nichiren Shoshu, a branch of Japanese Buddhism, has disavowed the Soka Gakkai sect, which also has its own political party. In its desire to counterbalance a communitarianism it regards as excessive, this movement, like the Agonshu movement, declares legitimate the expression of personal desires, and it asserts that individuals must find their own way, strengthen the personal element of their belief, and assume a certain degree of independent choice.

The Holy Spirit Association for the Unification of World Christianity was created by Sun Myung Moon in 1974. It was initially violently anti-communist, but after first scoring successes in Japan and the United States, has now allied itself with North Korea. This messianic group sees itself as the advance guard of a new humanity that will one day govern the earth. It regards marriage as the second birth of man and woman; and, as part of his aim of establishing the kingdom of God on earth and the future unity of nations and religions, Moon himself selects and proposes spouses for his followers, who live in communes.

The Divine Light Mission of Guru Mahara Ji, founded in India in 1960, offers its disciples spiritual knowledge through meditation. Trust in the perfect Master is essential, whether the disciples live in *ashrams* or in their own homes. Transcendental Meditation, introduced into the West from India in 1960, uses concentration on a ritual formula to achieve a simple state of consciousness. The practice, which is used as a relaxation technique in American institutions such as the army, universities and prisons and in some monasteries, is said to have been scientifically tested.

The Church of Scientology, founded by the American L. Ron Hubbard, also offers a means of transcending the ordinary state of self-consciousness. To this end, it employs an explanatory theory of the world and techniques of psychological contact, which the members learn on fee-paying training courses. Although often criticized by former members for using indoctrination methods at variance with human rights, it is extending its influence while attempting to gain legal recognition as a fully fledged church.

The various sects of Latin America have developed out of their own syncretic religions, drawing on Afro-Indian, Christian or spiritist components and the various Catholic and Protestant revivals. The traditional *candomblé* of Brazil, which has practically disappeared, used the cult of the Catholic saints as a cloak for the secret worship of the spirits of Yoruba origin known as *orixas*. Animal sacrifices conducted in the nagô language enabled spirits to be contacted directly through trance-states. The claim to African authenticity, here extended to cover the Caribbean, is expressed through the assertion of kinship links with African ethnic groups. *Umbanda*, which has an impact among the white urban middle classes, borrows the element of collective trance from *candomblé*, and that of possession by the spirits of nature from the native Indian cults. Other borrowings from spiritism include communication with the spirits of the dead, the idea of spiritual progress through reincarnation, the duty to do charitable works and a certain idea of a historical reason governing the evolution of spirits.

In 1992, the Assembly of the Council of Europe issued an important statement on measures to counter abusive activities on the part of sects. Rather than recommending new legislation – which would be very difficult to draw up at the international level while still respecting freedom of conscience – it suggested that all available resources of existing local law be used to that end.

## The renaissance of the Russian Orthodox Church

With 90 per cent of its members in the former communist countries, the Orthodox Church went through a long struggle for survival before experiencing a genuine renaissance after 1988. Its autocephalous churches, organized into five patriarchates, with that of Constantinople enjoying symbolic and historic pre-eminence, are theologically federated and manage themselves collectively through Councils. These churches, which are often defined on territorial lines, are in some cases national churches, as in Greece, or exist within specific national boundaries, as in the case of Russia, Belarus or Ukraine.

The Russian church, persecuted by atheist propaganda after the 1917 revolution, but granted the right to exist under Stalin, acted in a relatively docile manner. This was the price to be paid for its survival at the international level while it underwent persecution and prosecution at home, particularly after the new atheism offensive of 1959. Though it had its own sources of income, it could function only liturgically, and thus encountered a serious problem of transmission, being unable to provide religious education for its clergy and lay members.

The collapse of the regime in 1989 left the Russian church in a quite unprecedented situation. For the first time, it found itself free of state control and faced with a situation more akin to the French style of 'laicity' than its own historical tradition. It has had churches restored to it, has opened monasteries and theological schools, and has even been permitted to build new churches. Having had to assume responsibility for its patrimony, it is now impoverished and has even called for its old property and revenues to be restored in order to reduce the burden of debt. It has also begun to establish social and charitable organizations, but it is short of people, and its intellectual tradition needs updating, having been isolated from religious scholarship for eighty years. For this task, it does not yet have the means to introduce new ideas into its preaching, publications or youth activities, as does the Greek Church through its Zoë movement. It receives aid, often the subject of controversy, from missions of the Uniate Churches (Eastern Rite Catholic), which have places of worship they wish to recover, or from wealthy American Protestant missions.

Patriarch Alexis II, elected in 1990, is faced with ultra-nationalist, fundamentalist, anti-Semitic and anti-ecumenical tendencies within his church. Ecumenism does, indeed, clash with the strong missionary stance of Orthodoxy; the latter has, for example, used its base in Alaska to develop an American church, drawing on the strength of the Russian diaspora, and has also built up a sizeable church in Uganda. The American Orthodox Church, which has been virtually autocephalous since 1970, is the fourth-largest church group in the country and driving a theological and liturgical revival; however, American Orthodoxy has not accepted the Patriarch's expression of repentance for past 'failings'. The Russian church, which is nationalistic, conservative and significantly influenced by its diaspora, is very active in the WCC, particularly in the Faith and Order movement, where it provides a link with Catholicism, transcending divisions through its vigorous Trinitarian theology.

## WORLD RELIGIONS AND INDIGENOUS BELIEF

Could it be that we shall one day need to classify these fragmented, fundamentalist, charismatic, syncretic and sectarian religious currents as global forms of religion while classifying the great institutional religious traditions as indigenous, localized religions? A twofold development – fragmentation of the great faiths accompanied by a proliferation of new forms of religion – has indeed characterized the end of the twentieth century, with its widespread attitude of believing without belonging. The geographical contour lines of religions are also becoming less distinct, since the resonances of the various religions are felt far beyond their places of origin. Global religions are becoming indigenous, culturally specific religions, while indigenous religions are being exported worldwide. A contemporary account of religion can no longer accord priority to the great traditions, such is the extent now of their fragmentation into scattered groups without a common credo. This fragmentation contrasts with the feverish ecumenism of the major organized religions, which, paradoxically, it reinforces. The established institutions find mutual reassurance in their common defiance of divisions or sects, without always understanding that these represent an effort on the part of an entire community to recover wholeness and provide itself with an overarching perspective, so as to move beyond its contradictory relations with the world.[4]

The second half of the century saw all the world's religions in a standoff with democratic modernity which, even though it has made little headway, is becoming the unchallengeable requirement. Religions are all trying, however falteringly, to follow or anticipate the slow but steady establishment of a universal substrate of open, tolerant, fraternal, humanistic secularism – this being the shared precondition for a coexistence respectful of the authenticity of different cultures in the modern age. In this sense, and even though it is characterized more than other religious movements by a constitutional fragility and complexity, Protestantism – or rather that 'reformed specificity of belief' – is becoming like the common source of inspiration for the current developments, whereby a fuller inner life for each believer is accompanied by a heightened sense of civic responsibility. Religions, by shedding their institutional character, are

clearing a space for a civil, ethical and secular cosmopolitanism of a quasi-Confucian kind, in which identity-related emotions become purely personal concerns. It is in this context that reactive outpourings of all kinds can be understood.

## Back to 'true' religion: fundamentalism in its various forms

No definition quite fits all the forms of religious extremism that are now omnipresent on the world stage, but what they do share is a vigorous reaction against modernity, rejection of an imposed secular model, and affirmation of transcendence in a disenchanted world. They accord religious significance to political action, direct their message at the younger people who have been relocated to places not deserving of the name of towns, and are led by middle-class elites who freely resort to modern methods of communication.

All these movements dissociate themselves from three aspects of current society. Firstly, they display a common hostility to modernity, which they see as ungodly and inseparable from secularization or laicity; they challenge the Western model of civilization with its universalist pretensions, and wish to reconstruct unadulterated communal identities. Secondly, taking account of the failure of the secular ideologies of liberation and progress, they propose an alternative both to materialistic, neo-liberal development and to actual socialism, particularly of the state-nation-party kind, the failure of which in Eastern Europe and the Arab countries has created tensions over questions of identity and made it necessary to find rapid remedies for economic failure. Lastly, the era of political federations and blocs has come to an end, leaving behind a welter of nationalist and ethnic claims which had been kept for too long in deep freeze, while centuries-old conflicts are also resurfacing to stoke up these tensions. These various forms of resistance present a head-on challenge to tolerant relativism, respectful of otherness, proposing in its place a mythologized version of the origins of religious society; they are nevertheless perhaps laying the groundwork, despite all their excesses, for a non-Western way of modernization.
