C. L. R. James's 1938 seminal text *The Black Jacobins*, and Eric Williams' 1944 tour de force, *Capitalism and Slavery*, tell the story of this Caribbean journey to justice. They constitute much more than foundation works in West Indian nationalist historiography. Both authors, born in colonial Trinidad and writing Caribbean history within its modern Atlantic context, made significant contributions to Western development discourse within the traditions of Enlightenment idealism. As critical realists they considered popular historiography indispensable to any attempt to locate philosophical ideals within recognizable terms of community living. In *The Black Jacobins*, James documents the struggles of the enslaved peoples of St. Dominique, the mercantile showpiece of French colonial capitalism in the West Indies, for freedom and social justice. In addition, he details the transformation of this successful anti-slavery rebellion into something much more elaborate in terms of Western history – the creation of Haiti, the Caribbean's first nation-state. In *Capitalism and Slavery*, Williams expands and develops the paradigm of African labour enslavement and European capital liberation, first outlined by James in *The Black Jacobins*, which became the basis of the revolutionary reorganization of productivity for European economic development.[1]

The James-Williams paradigm has had an extensive and discursive impact on thinking about the relationships between slavery, Western modernity and development discourse. In the Caribbean these works represent points of departure for studies in historiography, decolonization and the signal birth of an insider, Creole, nationalist canon. Both texts have received considerable criticism and enormous acclaim; they continue, half a century later, to stimulate the most expansive areas of Western historical writing. James's explicit intention was to locate the Caribbean politics of black freedom within the philosophies of European Enlightenment discourse. Williams's related concern was to illustrate the contradictory and paradoxical nature of modernist rationality as expressed in the economic and ideological effects of the application of the principles of political economy to the relationship between Caribbean slavery and European industrialism.[2]

Conceptually, *The Black Jacobins* and *Capitalism and Slavery* situate the Caribbean as the vortex of a wider Atlantic modernity that witnessed the interaction of Europe, Africa, and the Americas. For James, the politics of bringing Enlightenment ideas nearer to reality is seen as a mandate taken up by the enslaved against colonizers who sought to monopolize privilege and power. The Caribbean

in the aftermath of the Columbus enterprise is seen by Williams as culturally unique; *Capitalism and Slavery* is an economic study of Western modernity in action within the Caribbean space, while The *Black Jacobins* constitutes a statement of its exploding contradiction authored by subaltern people operating ideologically within the hegemonic philosophical paradigms of their oppressors.[3]

Columbus did not lie, as Caribbean culturalists and historians often assert. He 'did' discover the Caribbean. It was as real for him as any construction of knowledge within a specific cultural tradition could be. He believed that he had done so, and that Europeans would encounter a new and different environment within which they could collectively discover themselves as free individuals and citizens. Europe was liberated by the experience and its subjects became citizens while the colonized became natives. The conception and construction of the *Latifundia* and 'plantation', as the organizing principle of socio-economic life brought these worlds together. For the European they became a metaphor for renaissance economic rationality, civilizing modernity, and entrepreneurial freedom from the constraints of dehumanizing material poverty. The colonial mission, then, was a missile that launched the Caribbean, its European commanders and African cargoes, on the path to modernity on board the plantation enterprise that rose on the fumigated site of native ruins.

## Plantation culture

Caribbean plantation culture was in every respect symbolic of the signs of the times. Capitalist political economy found expression during the sixteenth and seventeenth centuries in a proliferation of mercantilist tracts on trade, finance, and manufacturing; their authors preached the values of large-scale production, surplus generation, and the accumulation of wealth through foreign trade. The plantation developed as evidence of institutional commitment to these principles, and in opposition to the traditional culture of peasant production, which was considered backward and ruinous to a modern nation. Large-scale production required extensive resource mobilization and strategic entrepreneurial planning. The Caribbean planter, therefore, was required to be global in both thought and action since productive resources were not readily available and had to be acquired from distant lands.

The Caribbean sugar planter of the mid-seventeenth century was celebrated as the most successful agricultural entrepreneur of modernity. This social type was also considered entirely unique and unprecedented in terms of the global scale of their operations. They were identified as icons of Europe's economic ascendancy and designated the leaders of Atlantic modernity. The global network that fed their business was truly impressive. Having pacified and, in some places, exterminated the resisting native populations, they resorted to importing servile indentured labour from 'back home' and enslaved labour from Africa. They produced crops with capital and credit from Europe, imported food and building materials from mainland colonies, and exported their commodities globally. Facilitated by a transcontinental complex of brokers, agents, and financiers, the West Indian sugar planter held the known world with his gaze and 'made good' with the extensive array of goods produced. Using their economic success to maximum effect, they lobbied and

bought their way into metropolitan parliaments and imperial courts in an effort to protect and promote the world they had made.[4]

The Caribbean plantation was also home to other contradictory processes of modernity. Industrial technology in its most advanced state could be found there in the form of the sugar mill. Described as a 'factory in the field' the Caribbean sugar mill was probably Europe's largest industrial complex in the sixteenth and seventeenth centuries. Its deployment of state of the art production systems, energy and chemical technologies, and a disciplined labour force, set it apart as something altogether innovative and futuristic. The manner in which agricultural and manufacturing processes were intertwined – field operations and the mill – also distinguished the plantation as a cutting edge organizational technology. It was all achieved, however, on the backs of enslaved, dehumanized persons. Labour systems founded on them carried titles such as *economienda*, debt peonage, chattel slavery, indentureship and apprenticeship. Free wageworkers constituted a very small minority, and were not institutionally encouraged. Slavery, in its many guises, was the expectation, and persons categorized as 'Indians' and 'Africans' or colonized others were targeted for life-long experiences with it.

European Enlightenment discourse, then, invented the Caribbean and promoted the idea that slavery was progressive and developmental for both parties to the power relation. That Caribbean modernity should begin an outbound journey with Admiral Columbus taking a 'sample' of island natives to Europe for sale and show, as a strategy to recuperate project expenditure, speaks to the way in which philosophy, economics, and morality came together as integrated systems of pro-imperialist knowledge. There was, therefore, nothing particularly phenomenal about John Locke, doyen of Enlightenment writers on civic freedom and human liberty, owning slaves and investing in Caribbean (Bahamas) plantations.

Locke's participation as an investor in the colonial project began with the Royal African Company, which, under the Restored Monarchy, was given a monopoly to supply enslaved Africans to the plantations in order to further the competitive interests of the English nation-state. There was nothing modern about Africans, Locke thought, which would entitle them to inclusion in discourse about the rights of individuals. Rather, he considered them savages to be enlightened and civilized by Europeans. Slavery for him, then, was a sort of beginners' school in which Africans would one day acquire the basic characteristics that would entitle them to membership in civic society.

The racist nature of pro-slavery ideology that emerged in the context of slavery's expansion throughout the hemisphere tore at the intellectual and moral coherence of Enlightenment thinking, and revealed it as ideologically driven knowledge constructed to serve what critic Edward Said calls the wider purpose of culturally preparing European nations, or the white 'race', for the age of imperialism. Williams' *Capitalism and Slavery* outlines the economic, or 'rational', reasons why slavery was preferred as the dominant labour institution by colonizers. But chattel slavery was more than a labour system; it was part of a political campaign to culturally differentiate the European from the rest of humanity and to establish representations of a self-serving ethnic pecking order for the enforcement of 'otherness' upon colonized peoples. Liberty, justice, and freedom would not be legislated as real objectives

for these categories of inhabitants who would be represented as outside the gaze of Enlightenment. Williams, furthermore, after mapping the financial circuits of wealth accumulation and money flows that made slavery viable, concluded that modern industrialism in Western Europe has its roots sunk deep in the veins of enslaved Africans.[5]

Western modernity, then, properly understood, should be viewed from the Caribbean with ambivalence. The writings of principal pro-slavery theorists reveal the reasons why such an argument can hold. Edward Long of Jamaica, writing at the end of the eighteenth century, considered it sufficiently important to seek conceptual reconciliation of the reality of African slavery and the idealism of European freedom within the context of the colony's status as the wealthiest within the English Empire. Africans, he said, were freer as slaves in the Caribbean than as subjects under tyrannical, unaccountable monarchs and chiefs in their homelands. Slavery, for him, was an institution within which Africans made real progress towards freedom; in addition, an added bonus was that they benefited from exposure to modern European culture and technologies. As a transitional state, then, slavery for Long offered Africans measurable long-term benefits, which made it ultimately a modernizing and progressive institution. These views were published, with discernible strategic nuances, by writers in other imperial systems such as Moreau de Saint-Méry and Hilliard d'Auberteuil in the French Antillean colonies.[6]

James's strategy in *The Black Jacobins*, was not to engage pro-slavery theorists on the internal composition of their arguments, nor to challenge the firmness of the ground on which they were ideologically situated, but to seek terms of inclusion through the adoption of universalisms. The notion of Enlightenment, he argued, had at best a temporal relationship to European culture. He recognized and embraced it as a process in human development with a history that flowed through several civilizations – including those of Africa. In this sense, its European moment was just that – a passage too short to be nativized and denied its essential multicultural ancestry and texture. It was, furthermore, a merger of historical ignorance and ethnic arrogance on the part of imperial Europeans who sought to show that the new conditions of social living were culturally linked to their nations.

It was understandable, James believed, that Enlightenment ideals found political agency in Western European societies at the moment of Caribbean adventurism. In these circumstances, however, they were severely compromised by the cultural needs of colonialism that centred around the promotion of Caribbean slavery as indispensable to Empire. History determined that it was incumbent upon the colonized subaltern, the enslaved of the Caribbean in the first instance, to claim as a right judicial and social access to this idealism, and to do so through collective opposition to imperial power. Only such politics, James showed, could constitute the resolution of modernity's contradictions, and best illustrate the transforming powers of Enlightenment in action. The subaltern included not only slaves – the black Jacobins – but also disenfranchised women, indigenous peoples, and other marginalized groups denied social justice by managers of the imperial project. The opposition vanguards so constituted, James believed, would ultimately bring home the true value of Enlightenment ideas and render obsolete the racism and sexism standing in the way of human progress.

## Revolutions

James chose the Haitian Revolution, 1791–1804, as the discursive device best suited to giving intellectual coherence and social reality to his argument. It was not surprising that enslaved blacks, and their free mixed-race allies in St. Dominique, took the anti-slavery revolt to the revolutionary stage by seizing the state and declaring national independence. St. Dominique was the most populous and financially attractive colony in the Caribbean at the end of the eighteenth century. The relationship between slavery and capitalism, as conceived by Williams, had combined to render the colony the golden crown of colonial success. At the same time, argued James the Marxist dialectician, anti-slavery consciousness among enslaved blacks and disgruntled mixed-race peoples, as well as their organizational skills, were highly developed. Anti-slavery mentalities with revolutionary commitment were being created at a rate in the colony that corresponded with its reputation as the producer of the most of everything in the Caribbean. Toussaint L'Ouverture, revolutionary leader and theoretician of Enlightenment praxis, appeared as the logical and inevitable consequence of a society so proud of its economic success.

But James did not end his analysis here; he went on to explain that inasmuch as slavery was a product of renaissance rationality, anti-slavery politics was the social effect of modernist idealism. No other figure in the Atlantic, he suggests, was as perfect an example of Enlightenment activism as Toussaint. The struggle in the colony for the liberty of man against the enormous weight of feudal backwardness and reactionary opinion constitutes the epic drama of the quest for Caribbean modernity. The Americans had gone to war against British colonial exploitation and won. Driven, they said, by the thirst for liberty, the philosophical idealism of their contest was compromised and betrayed by the decision to keep chattel slavery as the principal organizing social institution within the new, independent dispensation.

The American Revolution was tarnished and discredited by this unwillingness to declare the liberty of all persons. Citizens were forced by the inevitable maturing of the politics in which they were engaged to go back a century later to the battlefield in order to resolve the matter by one of the bloodiest civil wars in human history. French revolutionaries abolished slavery in 1794 and restored it a few years later because they could not see national interests being served better without it. The blacks of St. Dominique, then, were the first to declare the universality of liberty, which they built into the national constitution of Haiti, committing a state to eternal opposition to chattel slavery. Enlightenment idealism was rescued and historically legitimized by enslaved Caribbean people who were not expected to be its beneficiaries. Without Haiti as its principal expression, James would suggest, Enlightenment idealism would soon have been discredited as a ruling class philosophy serving limited self-interests.[7]

If James's concern was to illustrate Europe's and the Caribbean's conflicting philosophical passage within Western modernity, Williams' text was conceived as an articulation of slavery's changing relationship to economic rationality. Primitive capitalism, Williams showed, called Caribbean slavery into being as the main mechanism of Western wealth accumulation, while advanced capitalism,

driven by industrial and scientific technologies, banished it from whence it came, aided by the instrument of Parliamentary legislation acting within a context of moral and philosophical outrage. It was the triumph of the market, argued Williams, not the long-in-coming assistance of Enlightenment moral idealism that made legislated emancipation all the more magnificent and historically seminal. William Wilberforce, the (white) man of the moment, says Williams, should not be diminished within this materialist interpretation of history; rather, he should be accurately situated and understood as leader of a 'political' strategy that may have forestalled the production in the Caribbean of a thousand Toussaints.[8]

Emancipationism, in the form of European parliamentary politics, however, took nearly one hundred years to sweep the region – across imperial lines – clean of chattel slavery. The Spanish were the first to establish slavery and the last to relinquish it, a history according to James that accounts in great part for Cuba's dramatic entry into revolutionary socialism under Fidel Castro. Capitalist economic rationalization, as Williams argued, may well have been the hidden force behind the Parliamentary legislative anti-slavery strategy. The industrial and commercial maturation of capitalism was rather drawn out in the Spanish Empire and the economic history of slavery in its Caribbean colonies illustrates this all too well. Slavery was finally toppled by a largely Creole, politically complex opposition that featured prominently the slaves themselves, who went to great lengths, as anti-colonial anti-slavery revolutionaries, to win their liberty.

If the freeing of the 'lower' orders, as Cromwellian revolutionaries called the working classes, was a principal feature of the onset of modernity, the Caribbean 'slave' within Jamesian analysis was ahead of the times as a self-liberator. In the case of Haiti, slaves seized a state and moulded a world in accordance with their own ideological praxis. For James, a practical effect of plantation production was to advance the proletarianization of the enslaved worker. Outside the judicial process that defined them as slaves, the African worker was certainly the prototype of the modern industrial worker. Organized by a division of labour into discrete productive units, trained in a sophisticated way as skilled artisans (particularly in the case of the sugar refinery personnel), and as middle managers, plantation slaves contributed to a political discourse that promoted the democratic values of social justice and equality. In this way they ensured the social unacceptability of slavery as a fascist relationship of power, and centred Enlightenment ethos within popular culture.

The year 1804, rather than 1917, was for James the first fulfilment of this ethos. The rise of the Haitian State rather than the Soviet Republics constitutes that first moment in modernity when the alienated and dispossessed seized control of their destiny and emerged the subjects of a new world order. Haiti became the mirror within which Europe saw itself as the Janus – divided to the soul – of its own contradictory imperial experiment. The civilizing mission became the journey of a thousand atrocities that culminated in genocidal actions against natives that refused to give up their lands, liberties, and lives. When President Dessalines in 1804 named the new republic Haiti – reinstating the island's Arawakan language identity – it was an act of heroic self-denial that placed the struggle of Africans and mixed-race peoples in a secondary relation to that of those who had greeted the Columbus mission and were later sunk by its missiles. The year 1804, then, was at once a torpedo launch, and the inauguration of a new order in which it was demonstrated that the rights of man could be achieved through resistance from below by the disenfranchised.

## Literature

These movements for liberty were accompanied by a body of literature within which the enslaved spoke back and countered the ideological representations established within the texts of slave owners, and their authorized supporters. Slaves wrote memoirs, letters, and narrated their life-stories to collaborators in the anti-slavery struggles. This literature constitutes the canon of a Caribbean political philosophy. The memoirs of Mary Prince, the autobiographies of Esteban Montejo and Olaudah Equiano, and other such texts exposed the cosmologies of enslaved communities and situated individuals within the wide, elastic vanguard of anti-slavery consciousness and politics. Taken outside its immediate situation, this literature, in which the subaltern speaks, illuminates their socially uncompromised and intellectually honest attachment to Enlightenment idealism. A comparative reading of Locke on liberty and Mary Prince on freedom should expose the emptiness of Eurocentric race and class claims to textual authority, and validate James's belief that the speeches of Toussaint L'Ouverture were among the finest on the subject.[9]

But this literature by the enslaved goes some distance beyond its strategic engagement with Enlightenment philosophy. It constitutes the beginning of a post-coloniality in which African and Afro-Creole identities and ontologies are set out in subversive opposition to imperialism. Certainly, no post-colonial literary theory should emerge without a departure from this textual tradition that questions and rejects aspects of the European philosophical canon. Anti-slavery was undoubtedly an Atlantic movement, but the slaves, noted both Williams and James, were at the core of it. They were on the ground, developing resistance strategies as features of everyday life, and ultimately were the ones who implemented the first, and numerically the largest, act of emancipation. Furthermore, this early black literary tradition breaks with Enlightenment idealism on issues such as individualism, family, sex, ethnic and gender relations, religion and spirituality, perceptions of materialism, cultural difference, and the existence of universalisms.

## Identity politics

The demographic and cultural tendency towards hybridity and creolity, for example, that simultaneously divided and unified the social experiences of all persons within slave society stands ultimately as an oppositional movement to white supremacy ideologies as well as an early affirmation of inter-culturalisms that now challenge identity politics in the post-colonial world. The self-assault upon notions of racial 'purity' by managerial males of Empire whose exploitative sexual engagements with black women stands as a marked feature of colonial society indicates the public fragility, and private irrelevance, of the race theories that underlie European Enlightenment thinking. The size of mixed-race

populations can hardly be considered a reasonable measure of the extent of inter-racial sexuality. Rather, it should be seen as evidence of the failure to publicly suppress the private. Inevitably, the changing face of Caribbean society came forth to testify to the truth that colonialism lied. Hybridity was as much a subversive feature of the Caribbean's contradictory experience with modernity as any other, and may very well be an understated, if not negated, example of the 'Empire striking back' – even if, ironically, at itself.[10]

Freedom was demanded on all sides, but its meaning and social application in the hands of blacks went in directions radically different from those expected by European anti-slavery activists and thinkers. For this reason, English emancipation in action became a contested experience in which blacks had little reason to believe that 'massa day' was done. Post-slavery societies were politically charged with a protest culture that rendered them as unstable as their slavery antecedents. This can also be said of Haiti. Slave revolutionaries became petty peasants and disgruntled labourers within the nation-state and challenged the definition of freedom imposed by the military-landowning elite. They voted with their feet, undermined the productive capability of the economy, and forced the state to implement the 1826 Rural Code that sought to tie them to the land and penalized those who preferred unemployment or hillside squatting.

## Enlightenment and emancipation

Europeans and Africans, then, engaged Enlightenment discourse in similar and different ways. Differences were magnified by the challenges of post-slavery reconstruction. While Europeans could understand, and in some instances support, blacks' claims to social freedom, they could not agree that social justice required this freedom be rooted in conditions such as landownership, the political franchise, access to respectable professions, and involvement in large-scale mercantile activities. Blacks should be free to work for whites, they concluded, and be driven to do so by the threat of hunger and an unrelenting criminal justice system. European abolitionists, then, found it difficult to support blacks' demand for economic and political enfranchisement as articulated by their community leaders.

Meaningful land reform was out of the question. The plantation had to stay as symbolic and representative of economic globalization and white supremacy, and as a sentinel against Afro-centric peasant empowerment. Enlightenment, therefore, crashed on the rocks of the Emancipation it had supported in theory, and provided once again the philosophical basis of a repressive, authoritarian colonial political culture. The defence of the plantation as a civilizing strategy to ensure that the journey of modernity was advanced was articulated in the face of considerable black opposition to it as the principal institutional oppositional force to their realization of social freedom. The economic decline of Haiti was represented by whites as modernity in reversal. The peasant was backward looking and tied to Afrocentric culture. The plantation was progressive and tied to European culture. Haitianization for whites became the metaphor for the end of Enlightenment. Blacks maintained that in Haiti they were empowered, had capsized the European project, and were free despite their increasing material poverty. They were not going backward, but were charting a progressive new path for mankind.

These developments when taken collectively speak to the central paradigmatic feature of Caribbean modernity – the rise of the common citizen to institutional and cultural leadership. While the Haitian experience has no parallel in world history, the general Caribbean process that now sees the offspring of slaves in control of state apparati must be considered a principal expression of social freedom. That considerations of race affected adversely the ways in which European radicals received Haitian leadership in the early years, and that Caribbean societies continue today to be torn and tortured by ethnic conflict, should help to reinforce the argument that by turning the world upside down, Caribbean people found themselves having to cope with post-modern issues while still attached firmly to the modernist paradigm. Indications of this contradictory motion can be found in the personalities and preferences of both James and Williams, distinguished humanist 'Western' intellectuals (read 'English') but ideologically steeped in an anti-colonial milieu that forced them to be deconstructionist and post-modernist at a time when it was not fashionable.

James considered himself justified in the opinion that the Caribbean was not only at the heart of the 'West', but that the 'West' was invented in the Caribbean. Williams agreed, but recognized as James did that being situated in the 'South' of this 'West' meant that different forms of knowledge had to be constructed in order to function strategically. The challenge for Caribbean intellectuals, therefore, had long been to destabilize and deconstruct hegemonic notions of the 'West' in order to define the Caribbean as a 'southernized' Western project with its peculiar oppositional politics and identity. These strategic intellectual positions did not always win favour with radical political opinion. As a result many Caribbean people have gone for a sterile Columbus-bashing approach. They argue that the Columbus mission was traumatic, and had a profound but backward moral impact upon the modern Atlantic world; such persons have failed to grasp the significance of the invisible cargoes that Columbus carried; but this is where the analysis should begin, argued Williams and James.

On board, Williams tells us, were several unseen commodities: an economic ideology which was not yet labelled nor understood, but which came to be understood as something called commercial capitalism; the ideology of racism, which at that time was not clearly articulated, but which rooted itself in the Caribbean; the social ideology of patriarchy, which assumed the superior political and intellectual capacity of men over women; an intolerant Christian theology which defined other religions as primitive subtypes; an expansionist imperialist consciousness that focused on total territorial acquisition; and a rationalist philosophy that promoted the notion of materialism as the way forward for mankind. All of these things represented what the Caribbean voyage was all about. Columbus was not only a courageous sailor; he was a leader, an emissary of a new epoch; the flag bearer of market forces that had become endemic to European social culture, and of a civilization which was beginning to sail out of centuries of decay and stagnation and finding its identity within the context of an imperialist experience in the Caribbean.

Commercial capitalism signalled the beginning of the integration of the continents of the world into one economic system. It was in the Caribbean vortex of the Atlantic Basin that this international capitalism took its early cultural and social identity. Historians on both sides of the Atlantic have documented very carefully the impact of the slave trade and slavery upon world trade. They now know, for example, exactly how it called into being African resources, and the ways in which they were deployed upon the foundation of Amerindian genocide. Much of the discussion that is taking place in the Caribbean today about cultural identity, race, sovereignty and the fragmented processes of nation-building is all part of this legacy.

It is important to comment on the ideology of racism. For centuries prior to the Caribbean connection, it was rare to find within the literatures of Europe a systematic theoretical formulation of a white over black ideology. Slavery, of course, had preceded Atlantic colonialism, but the notion of black inferiority was not popular. Indeed, many of the slave systems of pre-Columbian Europe and the Mediterranean were based on a multiracial understanding of labour organization. As a result, therefore, most ethnicities experienced some degree of enslavement to others. In the enslaved labour gangs working on the estates, vineyards, and in the mines of southern Europe, many ethnicities could be found. It was after the Caribbean mission that slavery developed specific racial dimensions, and anti-black ideologies became culturally established within Europe. By the mid-sixteenth century it was widely represented in European texts that blacks were suited for subordinate slave relationships within the colonial order.

The association of materialist expansion with human progress in Enlightenment discourse reinforced commitment to this ideological development. It was accepted by colonial whites that the march towards economic development required the systematic enslavement of blacks. There was a clearly formulated view that it was necessary, morally legitimate, not only to enslave persons, but also to exterminate conquered people in an attempt to confiscate lands. The plantations had to be productive, and the mines had to go deeper; these objectives required land and servile labour. It was not possible to organize a free labour force in the war zones of the Caribbean. In addition, it was the belief and experience of Europeans that colonial frontiers were best developed and restructured by slave labour. The Caribbean, therefore, was constructed at the centre of a new philosophical and economic order. It was the theatre where a new dispensation took shape and first matured.

The principle of political economy that international trade was the surest way to achieve self-sustained economic development was articulated by advocates of colonialism in the seventeenth century who promoted the critical role of the Caribbean plantation system in wealth creation. What Williams demonstrated was that without the Caribbean's role in the colonial complex there would have been no eighteenth-century English industrial revolutions; and no English imperial ascendancy in the nineteenth century. C. L. R. James went further and developed the concept that West Indian people now represent, because of that history, a unique cultural type. Within the Caribbean new mentalities and identities were created: a new people who represent a melange of European, African, Amerindian and Asian ancestry. Almost every major civilization in the world was brought to the Caribbean in order to sustain the conditions for colonial economic growth. The West Indian, therefore, is a futuristic individual, linked to all major civilizations. West Indians are the first products of the modern world system.

When James's concept of the West Indian is placed alongside Williams' thesis showing how the Caribbean slave plantation complex generated wealth and created financial institutions for the modern world economic order, then it becomes necessary to look at the cultural role of race and colour within contemporary market economies. People of European ancestry continue to dominate resource ownership in Caribbean societies despite their loss of political leadership. In this regard, Columbus still sails! The Western white world did to Cuba in the twentieth century what it did to Haiti in the nineteenth; imposition of an international commercial blockade, refusal to grant financial assistance, and general economic sabotage. No modern nation can now survive without international connections. To understand the electoral defeat of Michael Manley's Jamaican socialism, the cannibalization of the Grenadian Revolution, and attempts to cripple the Cuban Revolution requires first a study of the history of the Haitian Revolution. The region has gone through all this before. There is nothing new about it.

## CONCLUSION

The Caribbean, then, has had a turbulent and divisive experience with Western modernity. Contests have been waged with Enlightenment discourse. Political, intellectual and cultural work in the region demonstrates this. One of the more important intellectuals of the Caribbean who stood at the crossroads of these polemics was J. J. Thomas, also a Trinidadian. By the 1860s and 1870s, Thomas was a formidable oppositional writer, political ideologue, and philosopher. He spent many years explaining and rebutting the racist Enlightenment opinions of nineteenth-century English intellectuals such as Anthony Froude and Thomas Carlyle. Froude had visited the Caribbean after emancipation, and on his return to England wrote a book in which he said that an injustice was done to black people when granted emancipation because they were culturally regressing, spending their days eating pumpkins and sleeping under coconut trees. He was supported by Carlyle, who argued in an essay entitled 'On the Nigger Question' that emancipation represented a retreat from the principles of progress and that the future of the region was bleak. Thomas exposed the race, class, and gender contradictions of European Enlightenment discourse, and spoke in defiance on the specific and unique features of a discrete Caribbean modernity.[11]

Tensions and contest with Caribbean modernity in turn could not be contained within the islands. They breached the walls of the insulating Caribbean Sea and began a journey to energize liberation struggles in those same places from which it had drawn ancestral populations. Garveyism emerged as a Pan-African paradigm which maintained that European modernity in all its forms must be resisted and defeated at all costs: philosophically in the academies, in the market relations of the economy, in culture and the arts. The challenge to oppressed people to mobilize against racism and Empire was taken up, and

Garveyism spread like 'wild fire' throughout the colonized communities, with over five hundred branches in North and South America, and Africa, in addition to hundreds in the Caribbean. Having embraced the Caribbean, Garveyism went global representing the voice of Africans and all racially exploited people. Euro-American elites sought to contain Garvey in much the same way that the Haitian missile was contained. It was absolutely necessary from the point of view of those who claimed representation of the Columbus voyage to ensure that Marcus Garvey's Black Star Liner did not sail.

The contest of Caribbean modernity continued. The Cuban Revolution, which consolidated the region's socialist cosmology, linked its own specific struggles with those of colonized people on the other side of the Atlantic. In much the same way that Trinidadians George Padmore and C. L. R. James were critical ideologues and activists in the liberation of Ghana, Cuban troops made possible the driving out of imperial Portuguese and racist South African armed forces from Angola, and the subsequent winning of independence for Namibia. In these dialectical ways Caribbean modernity, though fractured, torn and tortured, came to participate in the political liberation of African people.[12]

Despite the pervasiveness of these struggles, and the successes of the independence movement of the post-war era, there remain people in the Caribbean trapped in colonial relationships. They are powerless with respect to resource ownership and their economies cannot independently sustain adequate levels of material living. George Lamming, however, has consistently made the wider point – with respect to the empty formality of constitutionally independent nation-states – that those who govern don't rule. Ethnic minorities who have recently arrived, and those who inherited the mantle of a restructured slave mode of production, are still very much in control of the economic destiny of the region. The historical forces of continuity and change suggest that the overlap of modernity in crisis with post-modern discourses are creating in the region new conceptual frontiers for theoretical analysis. While one group of citizens celebrate 'Discovery day' and another 'Emancipation day' the past continues to dwell in the present and the resultant turbulence produces the enormous energy sources that define and propel the Cultural Revolution that is the Caribbean.[13]

## WEST ASIA AND THE ARAB WORLD

*Anouar Abdel-Malek,* coordinator

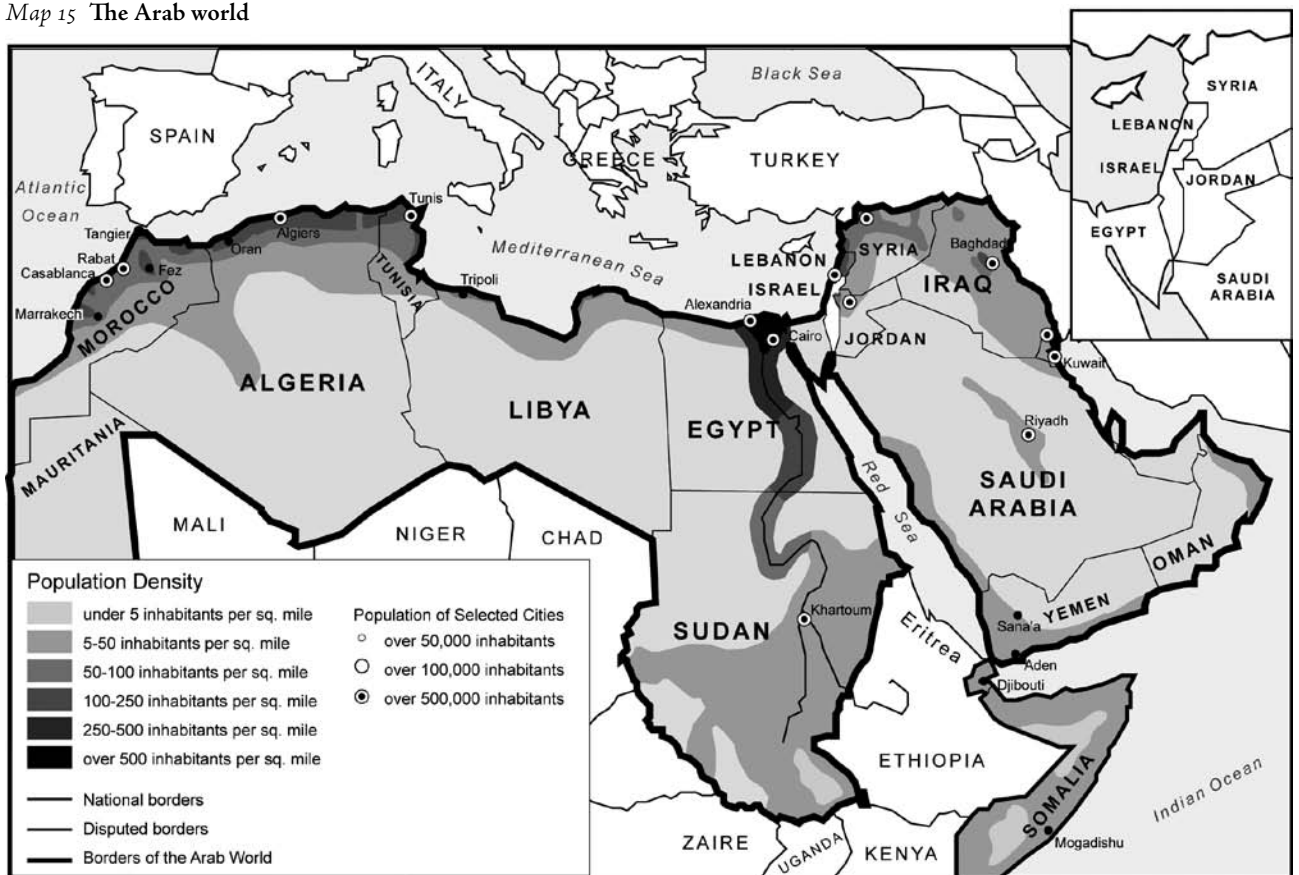
## INTRODUCTION

*Anouar Abdel-Malek*

In the present chapter on society and culture in West Asia and the Arab World, we will endeavour to examine the reality behind the turmoil of conflicts. The history of our contemporary world reveals a persistent pattern of conflict culminating in the twentieth century's two world wars, the Cold War and its aftermath, the rising tide of national liberation in opposition to imperialism, and, since 1991, the rise of globalism and hegemony. Simultaneously, resurgences in key areas, mainly in the eastern region of the Middle East, are opening new paths of development (Map 15).

This is an area of encounters and confrontations where the three monotheistic faiths have co-existed for thirteen centuries. Moreover, it is the focal point of invasions and confrontations between two of these faiths, and the region in which the three major religions are expected to converge. Until the 1990s, the ideological divide between the two

*Map 15* **The Arab world**



Adapted from M. C. Hudson, 1977, *Arab Politics: The Search for Legitimacy*, Yale University Press, New Haven, CT.

major economic and political world systems resulted in a race for allies in the region. To this day, the region remains the object of colonialism and imperialism, as the principal European powers, and more recently, the United States, have striven to control this strategic zone.

This explains the strained evolution of contemporary societies and cultures in the Middle East, now engulfed in the complex processes of globalization, which is rendered even more complex and acute by the region's immense oil and gas reserves. In this context, many specialists recognize the important, yet uneven, achievements in both infrastructure and production, which testify to the determination of all the societies under study to concentrate on the fundamental issues. Those persistent major efforts bear witness to the vitality and resilience of Middle Eastern societies, in spite of the mounting tide of pressures and threats, often exacerbated by the lack of adequate resources.

These efforts and achievements have more often than not attempted to replicate the institutions and processes of the advanced Western countries. Among the many contradictions are the conflict between the two types of evolution of the societies under review. The imitation of the more advanced Western societies has long been accepted as the dominant orientation. Such imitation has taken various forms: from the mere replication of institutions, values and processes of the advanced West, magnified by the impact of mass media, notably television, to the assimilation of the achievements of the more advanced societies. During an initial stage, imitation prevailed, particularly when decadence was rightly perceived as resulting mainly from the hegemony of the advanced West over the Middle Eastern societies. Imitation was thus accepted as the only logical choice of the new elites eager to join the ranks of modernity and expecting to be accepted as disciples and junior partners.

The second orientation in the societies under review proceeded from the constraints and failures of the first orientation. Gradually this became the prevailing perception among the rising national middle classes, divided by their recognition of their distinctive national cultures and the challenges of modernity. Hence the rise of endogeneity in the modernization and renaissance processes. Yet the deepening impact of globalization and hegemony can only increase the assertiveness of the members of Middle Eastern societies. Thus the stage was set for the dialectics between imitation and endogenous creativity at the heart of the socio-cultural processes of Western Asia and the Arab World.

## IRAN (ISLAMIC REPUBLIC OF)

### *Ali G. Dizboni*

The Islamic Republic of Iran is currently undergoing far-reaching social and cultural change that may be unique in the Muslim world. The reform movement symbolized by the 1997 presidential elections is the outcome of a lengthy transition from tradition to modernity. The twentieth century witnessed major political upheaval: from the establishment of the Pahlavi nationalist monarchy (1925–79) to the foundation of the Islamic republic (1979), which has for some years now been grappling with a powerful reform movement.

Historically, the cultural and scientific development of Iran has always been closely tied to political developments. Under both the monarchist and Islamic regimes, the development model has been characterized by the state's desire for radical societal change. Despite the quantative growth in development indicators, modernization and Islamization have had disparate effects and have failed to remodel the society or heal the wounds of transition.

As Boissel has noted, during the reign of the last Pahlavi Shah (1941–79), culture remained the exclusive privilege of the royal regime: 'Everything related to conservation, production and distribution of the arts (music, theatre, film, painting, crafts and audio-visual technology) received government patronage through the highly active and powerful Ministry of Arts and Culture, established in 1964, which has since been under the authority of a member of the royal family'.[1]

Culture was therefore managed by centralized national institutions. Firstly, the Society for the Development of National Music, which later became the National Music Conservatory of Tehran, was founded in 1945, and it was followed in the 1960s by the first National School of Fine Arts, the State Institute of Decorative Arts and the Higher School of Television and Cinema.[2]

The film industry, which dates back to the 1966–77 period, was strongly influenced by foreign productions (especially from the US). During this period, only 76 films were produced nationally, while 500 were imported. Production of the first films of international standard began in 1972 with films that often addressed social and economic issues.[3] After a post-revolutionary break of a few years, the Iranian film industry took off at the end of the 1980s, when it became remarkably successful and earned an excellent reputation on the international scene, winning a record-breaking 300 prizes[4] at international festivals.

In Iran, during the 1990s, there was a relative and fragile liberalization of culture, including the written press. The end of the Iran-Iraq war (1980–88), the American embargo and the challenges of economic reconstruction have, together with other factors, revealed signs of weakness in the religious regime. This is true to the extent that there was a ruthless struggle between conservatives and reformists, whom some have called post-Islamists.[5] The struggle resulted from the gap between the vision and capacity of the Islamist political model and the expectations of the population, 70 per cent of which were under 30 years of age. Intellectually, post-Islamism was defined by a thorough revision of Khomeinist ideology and objection to the conservatives' monopoly. The electoral programme of religious intellectuals, including President Khatami, took up the language of civil society and such issues as sovereignty of the people, limitations on judicial powers and on the prerogatives of the Leader of the Revolution, and finally, freedom of expression.

The press played a key role in the 1997 presidential elections by rallying public opinion to the reformist candidate, Khatami. The number of journals and newspapers peaked from 830 in 1997 to 1,491 in 1998. However, since 2000, when a major crackdown on the press began, 80 of them have been closed down for 'press crimes'.[6] Of the 50 periodicals forced to cease their activities in 2001, only two have been allowed to resume publication. In addition, in the summer of 1999, the campus of Tehran University was the scene of the Iranian 'Tiananmen', savagely repressed by pro-regime militia forces.[7]

In 1998, censorship on other fields of cultural production was lifted, at least temporarily. The number of titles of books published reached 20,642, and of public libraries 1,304 (with a total collection of 9,605,508 books). There were 307 theatres, with 2,068 drama performances, and 173,060 cinema screens showing 60 films per year.[8] However, supply fell far short of the great demand. Several public television channels have been opened but do not cover the whole country, nor do they satisfy the diversity of demand. UNESCO statistics for 1996–97 show that there were 263 radio sets and 71 television sets per 1,000 inhabitants.[9] The use of satellite dishes is therefore becoming very widespread, especially in the big cities.

In the field of education, the illiteracy rate, which was approximately 80 per cent in 1962,[10] fell to 16 per cent for

men and 26.5 per cent for women in 2003, a remarkable success considering that the population in 2003 was 70 million compared with 33 million in 1979.[11]

Under the Pahlavi regime, as part of the reform package known as the White Revolution (1962), the state introduced a national system of compulsory, secular education in the Persian language, without gender discrimination, which was free of charge even at the pre-university and university levels. The Literacy Corps, made up of 47,000 young graduates of pre-university schools, became the new spearhead bringing literacy to rural regions. The programme was moreover copied by the clerical regime in the 1980s and renamed the *jihad savad amouzi* (literacy jihad), covering some 2,192 adult education schools.

However, religious schools run by the Shiite clergy, which had been tolerated and sometimes suppressed by the Shah's secular regime, have become very prosperous and widespread under the mullahs. Their diplomas are being increasingly recognized by the ministry in charge of higher education.

In the 1980s, the university education system was heavily purged following the outbreak of the Cultural Revolution (April 1980 to autumn 1983) supervised by the Supreme Council of the Cultural Revolution. The clerical regime then decided to close all 200 institutions of higher education in order to remodel the academic structure and impose a single university curriculum. Secularization thus gave way to Islamization designed to eliminate Western influences. The imposition of the *hijab*, the establishment of Islamic Student Associations and changes in school textbooks exemplify this new policy. The regime centralized academic administration under the Ministry of Culture and Higher Education.[12] Admission to university programmes is governed by 'ideological and moral' selection procedures.

An important development has been the emergence of private universities (*Danechgahe azade eslami*). These universities, often of inferior quality and designed for young people, which were founded in 1981 in an attempt to offset the insufficient capacities of public universities, have spread throughout the country. In 1993–94, such universities existed in 80 towns. The number of students enrolled in 2001 accounted for 40 per cent of the total of 1.45 million university enrolments.[13] After the private universities had been set up, Payame Noor University (a distance learning university) was established in 1987 by the Supreme Council of the Cultural Revolution and placed under the ministry in charge of higher education. These programmes are overseen mainly by primary-school teachers and civil servants.

The 12-year structure of pre-university education, based on the French system, has remained unchanged but school textbooks have been revised to meet the requirements of the Islamic regime. Emphasis has been placed on the teaching of Arabic, *lingua islamica*, as a second language. In the 1993/1994 academic year, 17,552,092 pupils were enrolled in 96,474 schools, which included 445 technical schools, 524 commercial and vocational schools and 73 agricultural schools. The Ministry of Education publishes 747 different school textbooks, totalling 100 million copies, each year.[14]

The brain drain remains a chronic problem. Until 1970, owing to the dearth of postgraduate university courses available locally, especially in engineering, students were forced to go to Europe or the United States. In 1976, there were 60,000 students abroad and 154,000 in the country,

70 per cent of whom were men. In addition, in 1978 there were 10,000 Iranian doctors abroad (almost the same number as in Iran). Iran needed at least 50,000 doctors to provide basic medical services, but there were only 750 medical graduates between 1980 and 1986.[15]

Beginning in 1983, the regime's scientific and industrial policy aimed to improve the situation by providing more postgraduate programmes through the expansion of public universities in the provinces and the opening of the private universities mentioned above.[16]

Few accurate statistical data are available on the state of scientific and technological development in Iran. During the reign of the Shah, royal patronage was extended to the science and industry sectors, especially strategic products (oil and gas). Foreign investment was allowed and the assembly industry became the model for technological development.[17] Above all, in the petrochemicals and nuclear fields, the huge oil boom of the 1970s led to massive projects that were not completed after 1979 and the Islamic Revolution. According to the British magazine the *Economist*,[18] 60 per cent of the Iranian economy is controlled by the Islamic government and 10 per cent to 20 per cent by semi-governmental foundations (*bonyad*).

Industry recovered only after the Iran-Iraq war in the 1990s. The energy (exploration and rehabilitation of production capacity) and military sectors remained at the top of the list of industrial projects. Development of the petrochemical industry was still the best option for diversifying export. The National Petrochemical Company worked with foreign firms and investors, and in 1998 it grew by 25 per cent, that is 10.5 million tonnes of petrochemical products.

According to analysts,[19] Iran 'now has all in all a highly diversified, quality industrial base (automobile, household appliances, chemicals, textiles, pharmaceuticals, and construction materials) which cannot, however, meet the country's needs or produce for export'.

The Ministry of Science, Research and Technology, successor to the Ministry of Culture and Higher Education, is officially in charge of the R&D sector through two affiliated institutions: the National Research Council (Shoraye Pajoohesh Keshvar) and the Organization of Scientific and Technological Research (Sazamen Pajoohesh-haye Elmi va Sanati). In fact, other ministries (such as Defence, and Health, Hygiene and Medical Education) and other semi-governmental foundations have their own scientific and technological research institutes. For instance, in addition to university research centres there are other bodies such as the Institut Pasteur and the National Bio-Informatics Network.[20] The fragmentary nature of the research centres, overlapping and the lack of coordination under a national scientific development strategy are impediments to the optimization of financial and human resources.

Although pure sciences and engineering account for 50 per cent of enrolments in public and private universities, the Ministry of Science, Research and Technology recently deplored the state of advanced research. It emphasized weaknesses, such as: the living conditions of teachers; lack of dynamism in universities; the need to optimize information and communication technologies, and increase investment in scientific development; and the lack of an organic link between industry, the financial sector and the management of universities, due, among other things, to

the highly theoretical nature of university curricula.[21] This appraisal is confirmed by a United Nations report which states that in 1996 there were 0.7 scientists per 1,000 inhabitants and that 0.48 per cent of GDP was devoted to R&D.[22]

It is evident that it is neither prudent nor easy to make a definitive assessment of the cultural and scientific development of The Islamic Republic of Iran. The ambivalence of the political situation and the paradoxes of transition mean that there is reason to be methodologically pessimistic. On the other hand, the positive trend, at least with regard to the quantitative growth in certain cultural indicators, calls for measured optimism on our part.

## TURKEY

# 34.2.1
## TRANSFORMATIONS IN THE FIRST HALF OF THE 20ᵀᴴ CENTURY

### *Sina Akşin*

The Ottoman Empire, insistently called 'Turkey' by Europeans, was a well-organized structure based on the principle of ethnic and religious coexistence. Its weakness was its basically feudal character. Capitalism could find little room for development and the Turkish bourgeois class was almost non-existent. The Turks were late in adopting the printing press, which only appeared in 1729. Mosque schools, followed by the medrese, were archaic and almost entirely religion-oriented. To a large extent situated on European soil, the Empire had to modernize if it was to continue to exist. The seeds of this indispensable revolution were sown by the establishment, during the reign of Mahmut II (1808-1839), of modern schools of higher learning. These were, to start with, the School of Medicine (1827) and the Military School (1834). As the number of their students and graduates grew, they secretly organized to form the Committee of Union and Progress (CUP, 1889), composed of civilians and military officers.

### THE CONSTITUTIONAL REVOLUTION AND ITS COUNTERREVOLUTION

Thanks to the military officers who were graduates of the Military School, and were also mostly members of the CUP, this organization was able to force the Sultan to apply the Constitution and order elections (1908). It is noteworthy that this development was parallel to similar events in Russia, Iran and China. Following the absolutism of Abdulhamit II (1876-1909), the revolution generated an explosion of relief and enthusiasm. The CUP had great ambitions. The Empire was to be modernized and in the process 'the sick man of Europe' was to be cured. At first Europe seemed to receive the revolution very favourably, but as time passed it developed a great aversion to the CUP.

The CUP retained a varying degree of power up until 1918. During these years revolutionary changes were instituted:
1. The legal infrastructure (laws and regulations) of a modern state was created.
2. With the abolition of censorship, a large amount of new publications – periodicals and books – appeared. Thanks to freedom of expression and the predominance of educated people, the content of educational programmes and books was much improved. Intellectual and political currents such as nationalism, Westernism, Islamism and socialism flourished.
3. As a result of new legislation and active encouragement from the CUP, capitalism began to develop.
4. There was a remarkable increase in funds allocated for education, which produced important advances.
5. This period also marked the beginning of the emancipation of Muslim women, with greater opportunities for education and work.

In 1914, the CUP government chose to join the First World War on the side of Germany and Austria-Hungary. The result was defeat, which discredited the CUP. The Unionists abolished their organization and the leaders fled the country. Vahdettin, who became Sultan in 1918, thought that with the disappearance of the CUP, he could stage a counterrevolution and revert to absolutism. Parliament was dismissed, and Vahdettin tried to curry favour with the victorious British. But Britain, supported by France and Italy, tried to impose the Sèvres Peace Treaty (1920) which not only dismembered the Empire, but disregarded the principle of self-determination, bringing the Ottoman Empire to the verge of extinction. This produced a reaction and the movement led by Mustafa Kemal began a struggle for national independence and constitutionalism. Constitutionalism materialized in the form of the convocation of the Grand National Assembly in Ankara. With due encouragement from the Allies, Vahdettin thereupon initiated a civil war against the Kemalists but was defeated. This was followed by the defeat of the Greek Army, which at one point had advanced up to Ankara. This military achievement enabled Turkey to make a very favourable peace treaty at Lausanne (1923) and gave Mustafa Kemal, as commander-in-chief, the necessary prestige and authority to conduct the Kemalist Revolution.

### THE KEMALIST REVOLUTION

The Kemalist Revolution was the result of the 'Sèvres trauma'. In order that Turkey never again face another Sèvres, the Turkish people were to become as developed as the Europeans – in the economic field as well as in the fields

of education, culture and science. The idea was that development should take place in every conceivable field (e.g. music, production of electricity, football and railroads). The philosophy behind this concept of wholesale, integral development was to be that of enlightenment, so that an end could be put to medieval practices and behaviour. The Kemalist Revolution was much more radical than the Constitutional Revolution, being republican and secular (the Republic was proclaimed in 1923 and the principle of secularism was written into the constitution in 1937).

A striking reform of the Kemalist Revolution was the alphabet reform (1928). The Arabic script had been adopted during the conversion of the Turks to Islam in Central Asia, and had been in use ever since. Now the Latin alphabet, with certain modifications and additions, was to be used. What made this reform possible was the fact that the literacy rate, which was 5 per cent in 1918, had by this time increased to only 10.7 per cent. Another reform was the language reform. In the Ottoman Empire the written language was so laden with Arabic and Persian words that the uneducated (notably women) could not understand it. Discouraging the use of such words and encouraging the use of Turkish equivalents, and creating new words when such equivalents were not available, became a campaign in the 1930s. The Turkification of the language (including the finding of equivalents for Western words) is an ongoing process. Thus, Turkish has been so transformed that the written language of the Empire is now called Ottoman to differentiate it from present-day Turkish.

The People's Houses and Rooms were a vital institution of the revolution. Mustafa Kemal decided in 1931 that the best cure for reactionary movements and obscurantism was culture. People's Houses were cultural centres active in nine areas, including the arts, sports, libraries, educational courses, lectures and social work. A total of 478 of these centres were created, together with People's Rooms which had a more limited scope, but numbered 4322. In 1933 Istanbul University was also reformed, unfortunately accompanied by the exclusion of about two thirds of its academics who were considered inadequate. At this time Hitler's regime was busy ridding itself of academics who were Jewish or otherwise in disagreement with the Nazi ideology. Of these, 142 were invited to Turkey, where almost all of them served until the end of the Second World War. They were first-rate academics and the level of development of present-day universities owes a great deal to their efforts.

The education of peasants was a great problem, owing particularly to financial destitution, lack of communications and the isolation of many villages. Before the death (in 1938) of Mustafa Kemal, who had become known as Atatürk, an almost miraculous solution was found. Boys and girls from villages were to be educated in Village Institutions (21 of them) as teachers, technicians and cultured persons and then sent back to their villages. This solution solved the problem of adaptation to difficult village conditions and communication with the peasants. It was also very cost-effective, since those children built their own Institutes and grew their own food. The revolution, unlike fascist or fundamentalist ideology, also attached great importance to the equality of the sexes. The emergence of the first professional women – lawyers, doctors, pilots, diplomats, MPs – was greeted with great celebrations.

In 1945 President İsmet İnönü (1884-1973), who succeeded Atatürk, decided to inaugurate the multi-party system. In 1950, his party lost the elections, and the new government reversed some of the reforms introduced by its predecessor. For instance, the People's Houses and Rooms were closed down in 1951, and the Village Institutes in 1954. However, these changes had limited effects, progress continued in many fields and economic development was broadly unaffected.

# 34.2.2

## DEVELOPMENTS IN THE SECOND HALF OF THE 20ᵀᴴ CENTURY

### *Timour Muhidine*

Turkey's geographical situation has determined its history, particularly its cultural history. The country's position in the geopolitical landscape changed in the period after the Second World War. Its Arab neighbours experienced rapid change because of the windfall from oil and the pan-Arab movement centred in Egypt, while the common border with the communist Balkans was a constant source of tension. But Turkey managed to assert itself as a hub of movement and trade in the 1980s: many conflicts within the country (guerrilla warfare in the East) and elsewhere (Chechnya, the Caucasus and the Gulf War) had a great impact on internal political developments and gave fresh impetus to its foreign policy ambitions. If the issues of oil and gas exploitation and the water reserves in southern Anatolia are also taken into account, then a shift may be seen to have occurred in the pattern of regional alliances: Central Asia (neglected until Prime Minister Turgut Özal came to power) became a central focus of attention, and agreements were implemented with Israel, a strategic ally. Thus Turkey once again took up a key position in the regional 'great game' confirming the break with the Arab world that dates back to the years of the First World War: most economic and cultural exchanges were conducted with non-bordering countries.

### A DISTINCTIVE IDENTITY

The distinctiveness of the Turkish model is perhaps best seen in certain historical and cultural aspects. Turkey retains a keen awareness of its imperial heritage, and this awareness has been heightened since 1990. Its position as a multicultural and multi-denominational state continues to fuel nostalgia and also feeds into – or offsets – the model of a modernizing secular state that it maintained until the mid-1960s.

Another aspect, which has mainly attracted the attention of sociologists, is Turkey's high mobility, both nationally and internationally (trade and emigration, particularly to Western Europe). This might be called a taste for nomadism rooted in the imagination of a nation that sees itself as continuing a 'long march' towards the West.

After a period in which the oral popular culture, often linked to mystic orders (the Bektashis, in particular), was rehabilitated (and, in more than one case, rediscovered), what

might be called the second stage of republican cultural life has begun, with the reappraisal of the Ottoman period, including both its zenith (the fifteenth and sixteenth centuries) and decline (the late nineteenth century), times of great creativity that gave rise to a host of political and linguistic projects. One of the major incentives was no doubt the opening of the Ottoman archives to researchers and the general preference for a more prestigious past than that of the Republic. A shift occurred from the cult of a martial system centred on the East (around the new capital, Ankara) to acceptance of the many cultures tolerated by the Empire. This no doubt accounts for the abundance of publications and research on social, linguistic, artistic and economic aspects of the period when the *millet* (nations) lived side by side. Interest in this period – over and above the antiquarian aspect – makes it possible to put things into perspective, assigning them their place in history as a means of achieving reconciliation.

The widening gap between urban and rural cultures became more pronounced in the 1970s: with the shift from a mainly rural country to one that was primarily urban, habits and language changed; the rural heritage in terms of customs, attitudes to health and food, the very idea of travel inside the country changed completely. The folkloric features of art also diminished considerably, and this may be regarded as mirroring a decline in the nationalism which had threatened to isolate the country.

### INTELLECTUAL AND ARTISTIC MOVEMENTS

The major world intellectual movements, especially Marxism and existentialism, gathered many followers in Turkey. Nevertheless, the question of what constituted a Turkish intellectual was debated mainly within the 'Anatolian' school, which stressed the cultural continuity between the land of Anatolia – considered in terms of its ancient heritage – and contemporary Turkey. The intellectual, Sabahattin Eyüboglu (1908–73), for example, defined himself in relation to Western classical culture – the humanities – and contemporary works rather than in relation to the Orient, whether Arab or Persian.

These trends were most strongly reflected in literature; the number of poetic works produced has increased in the

course of the century, and several writers continued to enrich contemporary Turkish poetry: Nazim Hikmet (1902–1963), Fazil Hüsnü Daglarca (b. 1914) and Melih Cevdet Anday (1915–2002). In the novel, best represented by Yashar Kemal (b. 1922), Turkish prose succeeded in portraying two major developments in the country's history: rural change followed by rural exodus and the emergence of a new urban Turk. In the arts, architecture and music held pride of place; painting often fell into line with major international trends, and attempts to reinterpret the traditional arts (naïf engravings, miniatures) were not very successful.

## SCIENCE, TECHNOLOGY AND EDUCATION

Rooted in a strong tradition of medical and Earth science education, scientific research expanded considerably only after the early 1980s. Governed by five-year development plans, research gained a higher profile owing to the large number of reports and congresses of TÜBITAK (Turkey's Scientific Research Foundation, founded in 1963), which were indicative of the progress and aspirations of a country dependent on Western science but nonetheless determined to control its own national development. The recent availability of works aimed at the public at large and of several scientific journals is an important sign of change in the general culture of a population that is by and large not scientifically inclined.

In telecommunications, Turkey has taken up the challenge of television programming: many of its broadcasts are transmitted to its neighbours and the countries of Central Asia. Similarly, in the field of education, Turkey exports an educational model (textbooks, radio and television programmes) to Turkic-language-speaking countries, asserting the influence of its secular republican model geared to a Muslim population.

Education made rapid strides when the Village Institutes were established in 1941, but that scheme was unfortunately halted in the mid-1950s. Since the 1980s, the strong support for education has found expression in the establishment of many state and private universities (Bilkent, the first private university opened its doors in 1984).

With the extension of the university network, the human sciences have also expanded considerably, as illustrated by the extensive translation and research projects in the fields of history, sociology and philosophy. What may also be regarded as a delayed effect of the structuralist wave has led to renewed creativity in the field of thought: the brilliant school of historians working on Ottoman archives, and the philosophers who have been won over to logic theories (Nusret Hizir) and Husserlian phenomenology (Nermi Uygur) are emblematic of a living culture.

In conclusion, we should note the emergence of a psychoanalytical trend of thought in Istanbul, drawing on the French tradition and on the practice of psychiatric hospitals established in Turkey since the beginning of the twentieth century. This is no doubt a clear sign that the individual is receiving greater consideration in a society in which the group has long had priority.

# AFGHANISTAN

*Roland Gilles*

Hemmed in between Iran, India and the steppes of Central Asia, with no outlet to the sea, Afghanistan was one of the poorest countries in the world at the end of the First World War. And yet it enjoyed some prestige in the international arena. It had been neither occupied by Britain nor annexed by Russia. Bounded together by their faith and their resistance to foreign influence, the Afghans shared a strong sense of historical identity, even though they were far from founding a nation. Their country, apparently unscathed by any form of colonial rule, was seen as a 'Citadel of Islam' at a time when the Ottoman Empire was collapsing, the sultanates of Central Asia were under the sway of Moscow and the Arab Middle East was under the protectorate of the Allies.

Its independence must, however, be put into perspective. Since the second Anglo-Afghan war, in which the British gained the upper hand (Treaty of Gandomak, 1879), Afghanistan had no longer been free to conduct its own foreign policy. The Great Powers had drawn its borders as a buffer state between Russia and British India (Mortimer Durand line, 1893). Change was brought about by Amir Abdurahman (1893–1901), who unified the country by clamping down on the Afghan tribes, including the Pashtun. Without breaking ties with Britain, he laid the foundations of centralized government in Kabul. He can thus be seen as the 'father' of modern Afghanistan.

His son Habibullah Khan, who succeeded him in 1901, maintained the agreements concluded with the British and embarked on a process of economic development. On the educational front, higher education establishments were founded to educate the future Afghan elite. Habibiyia College was opened in Kabul in 1903, followed by a teacher-training college and a military academy. Reformist and nationalist ideas championed by Mahmud Beg Tarzi and his newspaper *Seraj-ul-Akhbar* were well received by the amir. These ideas, very much inspired by those of Jamâl al-Dîn al-Afghani, claimed that Muslims should seek in their religion – since it advocated the quest for knowledge – the principles and forms of a new approach to modernization, distinct from the materialistic and atheist approach of the West.

## KING AMANULLAH AND THE BREAKDOWN OF THE NATION-STATE

In February 1919, Habibullah was assassinated under mysterious circumstances. One of his sons, Prince Amanullah, seized power. He broke off the agreements with Britain and launched raids on several Indian border posts. This marked the beginning of the third brief Anglo-Afghan war. The British, weary of these perpetual conflicts, signed the Treaty of Rawalpindi, which gave the Afghans ample latitude to conduct their own foreign policy. According to the terms of the treaty, the Afghans were to be granted full independence in 1921. Two years later, Afghanistan was endowed with its first constitution, which bore the imprint of Mahmud Beg Tarzi: all Afghans, whether Muslim or not, had equal rights and were citizens of the state. The idea was clearly to replace the old tribal bonds and the *umah*, the religious community, by allegiance to the constitution.

In 1926, Amanullah, now on the throne, undertook a grand tour abroad. On his return to his kingdom, he stepped up the pace of the reforms, especially in education. Primary education was made compulsory for boys and girls alike. Afghanistan was on its way to becoming a kind of modernist nation-state on the model of Mustafa Kemal's Turkey or Reza Shah's Iran. But although technical modernization was accepted without difficulty by Afghan society, modernity caused resentment. The peasantry resisted the social reforms imposed by the king, particularly the ban on the veil for women and schooling for girls. At the end of 1928, revolt broke out. Insurgents led by a fanatical Tajik, Bacha Saqao ('son of the water-carrier'), captured Kabul in 1929. Amanullah fled to Qandahar, then abdicated. He died in exile in Italy in 1961. This episode demonstrated the obstacles encountered by the concept of nation-state when applied to a conservative peasantry divided by geography, origin and language.

## DIVERSITY OF ETHNIC GROUPS AND LANGUAGES, AND MIGRATORY MOVEMENTS

Some 17 ethnic groups, speaking as many languages, have settled on the lands making up Afghanistan. The country is divided into five major groups: the Pashtuns, the Tajiks, the Asian Turkic groups (Turkmen, Uzbeks and Kyrgyz), the Hazara and the Baluch.

The Pashtuns, who are Sunni Muslims, make up 39 per cent of the population. Traditionally farmers and warriors, they inhabit the regions extending from Jalalabad to Farah.

They regard themselves as the quintessential Afghans, since the dynastic state was originally formed by a Pashtun ancestor of the Abdali tribe, Ahmad Shah Durrani, who was crowned king in Qandahar in 1747. Enjoying preferential treatment from the authorities, they settled in the west (Khurasan and Badghis), the centre and the north.

The Tajiks, who are Persians of Central Asia, speak Dari or 'court language', a form of Farsi with an Afghan pronunciation that has become the language of administration and trade. It is in Dari that Afghans read the Persian literary classics, the poems of Rudaki, Firdusi and Hafez (consulted in the way the Romans consulted Virgil) and the works of their great national writers, Ansari, Jami and Sanai. The members of the ruling class, even those of Pashtun origin, tend to speak Dari, which remains the language of culture. The Tajiks, most of them small farmers, settled mainly in the west and north-east (Badakhshan and the Panjshir Valley).

The Hazara, of Mongol origin, are believed to have arrived in Afghanistan in the thirteenth century in the wake of Genghis Khan's armies, since the word *hazar* ('thousand' in Farsi) evokes a military unit. They gradually replaced the Tajik-Aimaq in the upper valley of the Helmand River and in the Bamiyan region. In 1893, their territory was conquered by Amir Abdurahman on the pretext that they were 'Twelver' Shiites. They speak the Dari of their Tajik neighbours and form a hierarchical tribal society with a considerable capacity for organization.

The Turkmen, from the Sultanate of Merv (Turkmenistan), settled the north of the country en masse around 1922, to escape the Soviet regime. They were mainly Ersari Turkmen living on the income from their herds. Tekke, Yomud and Chodor families have also married into their clans. In the course of the twentieth century, these nomadic herders became partly sedentary, moving into the towns of Meymaneh, Andkhoy, Aqcheh and Mazar-e Sharif.

The Uzbeks, who invaded Khurasan in the early sixteenth century, settled in small fiefdoms in the north of the country until they were subdued by Amir Abdurahman. Both nomad and sedentary communities spoke a language descended from Chaghatay Turki. In the north, Uzbeks who continued to herd sheep and horses lived in yurts and were referred to by the generic term *kuchi* (nomads). Among them, the Lakai are renowned for their great weaving skills.

The Turkic-speaking Kyrgyz lived mainly in the Pamirs (Wakhan). They were nomads living at an altitude of roughly 4,000 metres in high valleys only accessible in the summer. They raised sheep and yaks.

The Baluch, whose language belongs to the West Iranian group, occupied the far south-west, the Dasht-e Margo Desert and the south of Helmand and Qandahar provinces. Mostly nomads, they moved about with their herds in these regions, which were devastated and transformed into desert under Mongol rule. Large groups of Baluch settled around Herat and in the north of Afghanistan, becoming peasants and small-scale herders. The women made very beautiful rugs.

In addition to these major Persian- and Turkic-speaking groups, there were the Nuristanis, descended from a very ancient Aryan migration, who remained unaffected by Islam until their territory was conquered by Amir Abdurahman; the Kohistanis, who live in southern Nuristan; some Arabs gathered in villages in the north; the Brahui, herders who are

neighbours of the Baluch and who spoke a pre-Aryan Dravidian language, and lastly the mostly urban Jewish communities, such as those living in the Chaharsuq district of Herat who left Afghanistan during the Russo-Afghan war.

## AFGHAN SOCIETY

The population, whose numbers at the time of King Amanullah can only be guessed at, stood at roughly 15 million at the end of the 1970s. Its diversity was in clear contrast to the definition of a nation-state. More importantly, the population was 85 per cent rural, attached to its lands and traditions, with factors of cohesion – Islam, kinship, community and tribal links – that lay outside the sphere of the state.

Islam was the foundation of all authority, the supreme criterion for judging individuals who would be no more than a handful of dust (*khâk*) in the immensity of Creation if they did not fear their God. Religion therefore permeated all aspects of life: family life, eating and drinking, manners, work, travel and battle. Everything happened according to the will of God the most great (Allahu-Akbar), and by invoking his name. Men wore turbans, cut their nails and trimmed their beards in a certain way in order to follow the example of the prophet Muhammad.

Islam is not only a belief system, however: it is also a source of education, law and, to a certain extent, a political project. The boys of a village learned prayers, passages of the Qur'an and the hadith from the mullah – who was often the only literate person in the community – since even though Arabic is not in the same language family as Dari, both languages use the same alphabet. Shari'a, the set of laws derived from the Qur'an, was for most peasants a respected source of authority in addition to – or in conjunction with – older institutions: councils of elders, water regulation, and so on. In non-tribal areas where the honour code (Pashtunwali) was not applied, shari'a was the backbone of criminal law and customary law. For Afghan Sunnis, who were in the majority, this legal framework took the path of Hanafism. On the political level, Islam certainly encouraged the practice of consensus and community assent. This form of Islam, under the reign of Amanullah, was traditionalist, although not without a transcendental element, as attested by the attachment of large numbers of Afghans (from the middle classes and skilled craftworkers, among other) to Sufi brotherhoods: Naqshbandiyya, Qadiriyya and Chistiyya. It was the form of Islam then pervasive in Afghanistan and mostly untouched by fundamentalist doctrines, like that of the Muslim Brothers which emerged in Egypt in the 1920s, or the older doctrine of the Deobandis of India, which was to serve as a model for the Taliban.

It would be wrong to contrast categorically the tribalism of the Pashtuns with the absence of tribalism among the Tajiks. It is true that the pyramidal structure of Pashtun society was more marked, from the family unit, the *qawmi jirga*, run by the patriarch, to the assembly of all the tribes, the *loya jirga*. It was, however, an ideal structure, contradicted by the perpetually shifting alliances between small groups and the widespread practice of blood feuds. On the other hand, social constraints and aspirations were the same. *Zan, zar, zamin*: women, gold and land – the three main concerns of Pashtun khans were also those of the Tajik landowner, only the names were different.

Centuries-old conditioning kept women or *Zan* in a state of virtual seclusion. In the countryside, Afghan women carried out their work with their faces unveiled. In the cities, they would not dare go out without being hidden under a *chadri* (burka). Marriage, arranged by the families, was the subject of lengthy transactions. *Zar, zanim*: gold and land – the peasantry, barely making a living from the hostile land, expected a certain redistribution of wealth by the local powers.

In this discreetly hierarchical society, the individual felt obligations towards their relatives, their professional environment (*qawm*), the regional chief and the mullah. A whole system of mutual obligations underpinned the society, which was not feudal in the medieval sense of the term as there was no oath of allegiance, or indivisible hereditary fiefdoms, but which operated on the basis of extensive clientelism accepted by all concerned.

In the face of this peasantry shaped by Islam and which considered itself already to be a society of law, the Pashtun rulers had little room for manoeuvre. Everything that came from the capital was considered to be superfluous or impious. The leaders were inconvenienced by the constant lack of subsidies, which hampered development projects and degraded public service. As Afghanistan was too poor and too resistant to taxation, and as income from customs taxes was inadequate, they turned to foreign assistance and external funding. This indebtedness threatened the country's independence and placed its economy in the hands of others.

## 1929–1978

Previously subject to the whims of Bacha Saqao (Habibullah Ghazi), Afghanistan was taken in hand by Nader Khan, a former commander of the army. He was a high-ranking Pashtun, of the royal clan of the Muhammadzai, a tribe of the Abdali. Acceding to the throne in 1929, he immediately had a new constitution drafted, which reaffirmed the predominance of Islam and respect for traditional institutions.

In 1933, King Nader fell victim to a feud. His son, Mohammed Zahir, was proclaimed king a few hours after Nader's assassination and he reigned until the *coup d'état* of 1973. Reserved, shy and cultivated, he was only 20 years old when he came to the throne, and for many years his uncles governed in his stead. Under the regency of Hashem Khan (1933–46), Afghanistan remained on the sidelines of the Second World War by observing strict neutrality. In 1946, Shah Mahmud, another uncle of the king, took over the regency.

## Prime Minister Daoud (1953–1963) – opening up to the USSR

In 1953, Prince Daoud, the king's cousin and brother-in-law, became prime minister. He also reinforced the role of the state and administration. To implement an initial five-year development plan, he appealed for help to the United States and the USSR. However, as the price of their assistance, the United States asked Afghanistan to join the Southeast Asia Treaty Organization (SEATO), which would have implied recognition of the Pashtun territory situated in Pakistan. Daoud, who had laid claim to the

territory, rejected the deal and turned to the Soviet Union. Cooperation with the USSR, which would be very close from the outset, in particular in the technical and military field, began in 1955. From 1961 to 1963, the crisis between Afghanistan and Pakistan worsened. The borders were closed, and King Zahir, worried by the situation, forced his cousin to resign.

## The constitutional monarchy of King Zahir (1963–1973)

Zahir's seizure of power was accompanied by a return to neutrality with regard to both the Russians and the Americans. Organized on a competitive basis, foreign technical assistance started to pull the country out of under-development. In Kabul, in the first mixed university faculties, women students were free to reject the veil. The quarrels with Pakistan died down.

One of Zahir Shah's first measures was to grant his country a new constitution (its third). It was significant. Broadly inspired by the French institutions of the Fifth Republic and the American Constitution, it was carefully drafted and was used as a model in 2003 by the government of Hamid Karzai. The text set out the principles of a constitutional monarchy, guaranteed an elected parliament, a free press and the removal from power of all members of the royal family except for the king. It had the merit of clearly establishing the separation of powers: executive, judicial and legislative.

The National Assembly elected in 1965 was composed of three political groupings: a small communist party, a majority party of the centre and, lastly, a large conservative grouping. The perpetual divisions in the centre party blocked voting on legislation and hindered the government's ability to act. Six prime ministers followed in quick succession without achieving much, and the parliamentary system was gradually discredited.

On 17 July 1973, a *coup d'état* overthrew the impotent constitutional monarchy. The army, led by republican officers and communists, took power and proclaimed a republic. Daoud, the king's cousin, was placed at the head of the government.

## The Daoud Republic (1973–1978) – the new political deal

When the prince president returned to power, the political and social situation had changed considerably. A significant middle class educated in state schools had emerged. Soured by the discrimination it experienced (the most important positions continued to be handed out to the Pashtun elite), this middle class turned increasingly to fundamentalist Islam, which seemed to offer a political blueprint, or to Marxism-Leninism, whose principles had been broadly disseminated ever since Moscow started providing assistance. In the 1970s, the country's two communist parties, Parcham (the banner) and the People's Democratic Party of Afghanistan (PDPA), which subsequently took the name of Khalq, attracted an increasing number of members, in particular among army officers and teachers. As for the Islamists, who were revolted by Daoud's modernist and secular tendencies, they organized an uprising in the Panjshir in 1975. The insurrection was harshly suppressed.

## Economic development under the Daoud presidency

Despite this political handicap, the prince president embarked upon an ambitious seven-year plan (1976–83). It was not the first time such a programme had been launched in Afghanistan – there had previously been three five-year plans since 1956, which had met with varying degrees of success. The first two (1956–61 and 1962–67) were intended to provide the country with the infrastructure it needed for its development. To carry them out successfully, Afghanistan received US$65 million in external aid, including 50 per cent from the USSR and 30 per cent from the United States. The third plan (1967–72) emphasized agriculture and industry and endeavoured to complete projects already under way. The more rigorous seven-year plan brought together data provided by the ministries and produced a more coherent policy. To counter the USSR's influence, Daoud asked Iran for aid of US$2.4 billion. The Shah agreed to give roughly half that sum. Based on Soviet models, the plan made heavy industry and the exploitation of iron and copper mines a priority. This was a debatable choice for a country which remained essentially agricultural.

Nevertheless, Daoud obtained some outstanding results. During the five years of his government (1973–78), the foreign trade balance, previously in deficit, went into the black. Major agricultural projects were launched and small-scale industry flourished, including the mechanical workshops where the ingenuity of the Afghans flourished. If an economic and cultural assessment is to be made of Afghanistan in peacetime, the period selected for such an assessment should be the Daoud presidency.

## Agriculture, livestock farming and rural development

Afghans have always been proud of their food self-sufficiency, as only 12 per cent of the land can be cultivated. It is divided into irrigated land (*âbi*) and dry-farming land (*lalmi* or *dayma*), the latter being in valleys or foothills. Cereal production was the most important, varying between three and four million tonnes under the Daoud administration. Wheat accounted for two thirds, barley and maize for the rest. Fruit came second among the food crops and played a major role in the economy of Afghans, who exported them or ate them fresh and dried. Industrial crops developed in the same years. Between 1972 and 1977, production of sugar (from sugar-beet and cane sugar) rose by 31 per cent, of vegetable oil by 153 per cent and ginned cotton by 215 per cent. In Kunduz, the dynamic business Spinzar harvested 164,000 tonnes of seed cotton in 1975. French technical assistance and hydraulic works on the Kunduz River enabled this cotton crop to be extended, under the control of the Uzbek Lakais.

To improve yields, large water-storage dams were built with mixed results, due to the absence of an adequate drainage system and a lack of consultation with local farmers. The Helmand and Arghandab river valleys were fertilized by dams built in 1952 and 1953. Alongside these major projects, a development policy more in tune with physical and human factors was introduced. The participation of the local authorities ensured the success of these projects, which were focused on varied food crops and creating experimental farms. A return to small businesses, managed by the peasants themselves and suited to the situation on the ground, started in the 1970s.

Inexpensive projects designed to improve agriculture and the rural infrastructure (roads, dams, canals and bridges) were then launched in Kunar, Badakhshan, Hazarajat and the Balkh region. For their part, the Afghans set up a Department of Rural Development (DRD) whose role was to promote the village economy – whether agricultural or craft-oriented – by coordinating the work of ministries. The cooperative movement was launched with encouragement by the state.

Livestock farming, like agriculture, was a major economic asset. One of the country's riches was its approximately 24 million sheep, especially the superb Karakul breed. Craftwork was another important source of wealth. Domestic crafts enabled women to make a significant contribution towards raising family income (sometimes as much as 70 per cent). In 1977, carpet exports were worth $24 million to Afghanistan, that is, 8 per cent of annual exports.

## Means of communication

In the Daoud era the network was improved. Asphalt roads, which by then totalled 3,000 kilometres, formed a ring around the country, passing around the central mountain plateau and the high mountains of the east. In 1964 the piercing of the Salang tunnel, 2.7 kilometres long, carved out at an altitude of 3,363 metres by Afghan-Soviet teams, linked Kabul to the Soviet Union.

## The industrial sector

Industrial activity developed in the 1930s with the creation of the Afghan bank Bank-i Melli, which funded projects up until the Second World War. One of the earliest success stories was the textile company Spinzar, which exploited the cotton crop of the Kunduz region. Founded in 1935 by a partnership of the banker Abdul Majid Zabuli and the businessman Abdul Aziz 'Londoni', it extended its operations to six other towns in the north in the 1970s. At the time the company produced oil, soap and ceramics and built housing and schools for its employees. When Daoud seized power, he nationalized the banks and to a large extent controlled industrial activity, including Spinzar. Thus, the public sector produced cement, sugar, ginned cotton, chemical fertilizers and most textiles.

However, Daoud's main aim was to provide the country with heavy industry by using its iron, copper and natural gas reserves. South of the Ko-i Baba chain, the iron mines of Hajikak had excellent quality ore. Unfortunately, they were at an altitude of more than 4,000 metres and extraction required costly infrastructure. The exploitation of copper at Ainak was much easier. The Sheberghân region in the north-west supplied natural gas, which was exported by pipeline to the USSR starting in the Daoud era. In 1975, the chemical fertilizer and thermal energy factory of Mazar-e Sharif started transforming this form of energy. There are coal reserves estimated at between 400 and 500 million tonnes – it is particularly abundant in Darra-i Suf – but they have yet to be fully exploited.

## The archaeological heritage

Development of the archaeological heritage began in 1922 under King Amanullah, after the signing of a convention with France, and continued until 1978. It was soon rewarded with success, notably concerning the Buddhist monasteries and stucco statues at the Hadda site, the discovery of the Bagram treasure hoard at Kapisa, the inventory of the Buddhist monastery of Fondukistan, and the excavation of a fire temple dedicated by King Kanishka on the hillside of Surkh Kotal. These discoveries have shed light on the sophisticated Kushan civilization (first to fifth century AD), the expansion of Buddhism in Afghanistan and the art of Gandhāra. A still more ancient past was revealed in 1964 with the remains of Ai Khanoum, a Graeco-Bactrian city founded on the banks of the Amu Darya after the conquests of Alexander. Islamic monuments of the Ghaznavid, Ghurid (Minaret of Jam) and Timurid eras were also studied and restored. A national museum established near the Dārulaman Palace under Nader Khan housed a significant portion of excavated artifacts. The clause giving France the exclusive right to research was annulled in 1952 by King Zahir, and Afghan archaeology was then opened up to foreign scientific missions under the auspices of the United Nations and its agencies. The Americans were interested in prehistory, and the Indians, Japanese and Italians restored rock chapels and the great Buddhas of Bamiyan. In 1974, the city of Herat with its many fifteenth-century Timurid monuments was inscribed on UNESCO's World Heritage List. By the 1970s, Afghan archaeologists had taken over. In 1978, an Afghan-Soviet mission excavated a necropolis at Tillya Tepe, west of Balkh, dating from the first century BC, with tombs containing thousands of pieces of jewellery in precious metals.

## Development of education

The first secondary education establishments were created in the 1920s in Kabul, during the reigns of Habibullah and Amanullah, and included the Franco-Afghan lycée Estqlâl, the Nedjat secondary school (German development aid) and the Ghâzi secondary school (British development aid). Subsequently, university departments were founded: the faculty of medicine in 1931, faculty of law in 1938, faculty of science in 1942, arts faculty in 1944, faculty of economics in 1957, engineering school in 1963 and the Polytechnic School in 1963 (with Soviet development aid). Most of these establishments benefited from foreign assistance: France for law, medicine and pharmacy; the United States for agriculture and education, and the Soviet Union for the polytechnic training. Afghan students went on study trips abroad. In 1972, 7,400 students were registered at Kabul University and the Nangarhar College of Medicine near Jalalabad.

In 40 years, from the monarchy of Nader Khan (1931) to the Daoud republic (1973), the number of primary schools rose from 22 to 3,800; the number of pupils from 135 to 760,400, and the number of primary-school teachers from 105 to 21,920. A 1974 UNESCO report underscored this constant development that would continue through the decade. Despite this remarkable rate of expansion, outcomes remained modest. USAID statistics showed that 87 per cent of the population remained illiterate. Only 24 per cent of children between the ages of 6 and 14 attended school, taking into account the fact that the proportion was higher in urban than in rural areas. Although urban families sent their children to school, villages resisted state schools strongly, in particular for girls. This hostility grew after the establishment of the communist regime.

## FROM THE COMMUNIST REGIME TO THE END OF TALIBAN RULE (1978–2001)

On 27 April 1978, a *coup d'état* fomented by the communists overthrew the presidential regime. Daoud and his family were assassinated. The Democratic Republic of Afghanistan, proclaimed by the insurgents, was recognized immediately by the USSR. Power was handed to the leaders of the communist parties: the leader of Khalq, Noor Muhammad Taraki, became president; the leader of Parcham, Babrak Karmal, became vice-president; and Hafizullah Amin (Khalq), second vice-president.

From the outset, the number of arrests, instances of torture and executions rapidly increased. There was considerable in-fighting between supporters of Khalq and those of Parcham within the leadership. Babrak Karmal was sidelined and Taraki assassinated. Amin took control of the state and stepped up the repression. Confusion reigned within the government as uprisings broke out in garrisons and in the countryside, where agrarian reforms were received with hostility. On 25 December 1979, the Soviet army entered Afghanistan, ostensibly to restore order. Amin was killed and Babrak Karmal returned to power. The Soviet occupation of the territory had begun, and with it emerged the Afghan resistance movement, which was to last nine years.

Faced with failure after a decade of bloodshed, the Soviet Union finally withdrew its troops in February 1989, leaving in place in Kabul a skilful administrator, Najibullah, who tried in vain to negotiate with the leaders of the resistance. The military victory of the Afghans was not followed by a political settlement. The mujahedin, more rivalrous than ever, fought each other for four years. Kabul, which had been more or less spared during the Soviet-Afghan conflict, was then reduced to rubble, including its palace and museum (1992–94).

The population was war-weary. Pashtun fundamentalist groups then appeared on the scene and took advantage of the situation. They were the Taliban, 'seminarists' trained in extremely strict Deobandi Qur'anic schools in Pakistan. The Taliban made the roads safe and enabled the resumption of trade. In September 1996, they took Kabul and killed Najibullah. Darkness fell on Afghanistan. Women were no longer allowed to work, girls' schools were closed down, shari'a was applied with an absurd rigour, the country's Shiites were massacred and the great Buddhas of Bamiyan destroyed. Under the Taliban and their leader Mullah Omar, the country became a training ground for international Islamist organizations, most of which were already in place during the Soviet-Afghan war. Among them, Osama bin Laden's movement stood out by virtue of its financial resources, armament, auxiliaries from all over the world and its apocalyptic messianism.

On 9 September 2001, the resistance hero Commander Massoud, who opposed the regime with his Tajik fighters,

was assassinated in his Panjshir headquarters. As a result of the 11 September attacks in New York and Washington, two days later, which were attributed to Osama bin Laden's network, the Americans decided to intervene. They drove out the Taliban with the assistance of troops of the late Commander Massoud's Northern Alliance. In December 2001, a provisional government was formed under Hamid Karzai, a liberal Pashtun. King Zahir returned to his country to support the new regime.

The transitional government, composed of 29 ministers, endeavoured to implement a programme of reconstruction taking regional and ethnic considerations into account. A constitution was drawn up resembling that of 1964. Nevertheless, the world is eager to see whether the new Afghan state will be able to achieve recognition of its legitimacy and implement its decisions after 22 years of conflict. Afghanistan is not only a country in economic and cultural ruins that needs to be put back on its feet, but one that has been reshaped by civil war, where differences between regions, ethnic groups and religions have been aggravated, and autonomous economies based on the opium trade, smuggling and the sale of arms have continued to flourish.

## SYRIA, IRAQ AND LEBANON

*Mahmoud O. Haddad*

At the beginning of the twentieth century, the three geographical areas covered in this sub-chapter were provinces under Ottoman rule, and the main problem then was the polarization between two opposing policies (each with far-reaching cultural political implications): the first emanated from the centre of the empire in Istanbul, calling for centralization; the second originated in the different local Arab regional centres, especially Beirut, Damascus, and Basra, calling for decentralization and for accepting Arab cultural nationalism as a component of Ottoman political patriotism. However, during the war, the Ottoman-Turkish authorities accused several dozen Arab intellectuals and activists in Syria and Lebanon of conspiracy to gain independence by siding with the Allied Powers, and they were sent to the gallows. This incident was greatly lamented by Arab poets through poetry that sang the praises of the martyrs. In fact, rhythmic poetry remained the main form of expression of political, social and cultural currents. Rhythmic poetry and the journalistic essay dominated the cultural field between the wars. The main topics of discussion were national, romantic and social. The short story, the novel and autobiographies were gaining popularity at the same time.[1]

### POST-FIRST WORLD WAR

Although the end of the First World War witnessed the dismantling of the Ottoman Empire, the result was not the formation of one centralized or even decentralized Arab state as Arab nationalists had hoped, but the creation of a British mandatory system in Iraq and two different French mandatory systems in Lebanon and Syria. As a result, the Ottoman administrative boundaries were modified, especially by the French in Syria and Lebanon. Evidently, the problem of political and cultural identity came to the forefront once again. Various intellectuals recognized the pre-eminence of distinct identities. Those who accepted the new British and French divisions defined the new nation-state identities in a way compatible with European colonial cultural and political values. The predominant position, however, gave primacy to Arabic culture and emphasized a form of Arab nationalism that could lead to the political unification of at least Syria and Iraq. While Arab nationalism

saw the need to borrow certain elements from European culture, it nevertheless did not accept it uncritically and perceived a long-standing, though sometimes partial, friction between Arab identity and European colonialism, which was expressed in most available genres of literature. This friction came to the fore most noticeably after 1924, when Turkey abolished the Islamic caliphate and declared itself a fully secular state following in the footsteps of the West. The rationale for this and similar steps was that the Western culture was considered the only viable culture in the modern world, and it should be accepted and emulated without reservations, i.e. with its roses and thorns. This kind of thinking was not acceptable in the Arab region we are focusing on since the element of tradition (*turath*) and traditional identity still held sway. There were different Arab responses to this pro-Western stance. Such secularization was tantamount, according to the Islamic reformists or modernists, to total rejection of the Islamic religion and identity. They perceived the Turkish approach as a complete departure from Islam and Islamic identity, not only in the sphere of the state, but also in society at large. This position, which supported Arab and Islamic values while remaining open to modernization, was best voiced by Muhibb al-Din al-Khatib, a Syrian émigré living in Egypt who wrote:

> Renewal and reform are not mere desires; they are necessities of the first order to preserve the last breath of national life and to protect the last vestige of national greatness. Otherwise, we would be as good as finished ... Renewal is necessary and inevitable if we were to carry out what we have been enjoined to do when facing enemies, namely 'to prepare all the power we are able to muster'. And reform is inescapable if we intend to shed the cloak of obsequiousness ... I do not hesitate to state firmly and clearly that ignorance is better than a renewal with which foreigners intend to 'colonize' our hearts to spare them the toil of colonizing our lands. That is because when we become theirs, the slave and his belongings belong to his master. Would the youth of the glorious Arab East accept this sort of renewal?[2]

In engaging in such controversies sparked by the Turkish national initiative, we must bear in mind that the cultural

sub-regions we are discussing were interconnected and not independent of each other, especially concerning matters related to Islam and Islamic culture. But while the mainstream intellectuals in Syria and Iraq and part of Lebanon insisted on anti-Western Arab nationalism expressed either in secular terms and referring to language and common history or in both religious and secular terms blending Arab nationalism with Islam, there was a third trend in Mount Lebanon (which was expanded by the French to create the State of Lebanon within its present boundaries in 1920) involving a distinct Lebanese nationalism, friendly to the West and especially to France, refusing Arab political nationalism yet finding merit in certain aspects of Arabic culture, especially the Arabic language.

Since Britain was less intrusive in the cultural affairs of Iraq, its capital, Baghdad, became the centre for disseminating official Arab nationalist culture, especially under King Faysal I (1885–1933). This was most evident in the teaching system supervised by the prominent Arab nationalist Sati' al-Husri (1876–1968) and backed by the ruling elite that was partly composed of both Iraqi and Syrian army officers who participated in the Arab Revolt against the Ottoman Turks during the First World War. But Beirut and Damascus remained ahead of Baghdad in most cultural fields.

The inter-war period witnessed an 'intellectual and cultural awakening'[3] in the Lebanese capital, Beirut, which maintained its prominent role in the exchange of ideas and as the main publishing centre for different political and non-political topics. Music, art and theatre attracted an audience and 'allowed individuals and groups to transcend their parochial identities and melt into a common cosmopolitan sub-culture'.[4] Damascus and Baghdad followed suit.

The Arab defeat in the first Arab-Israeli war in 1948, just a few years after these countries gained independence, was a blow to the traditional ruling elite, who were perceived as the stooges of the hated West. Oswald Spengler's book *The Decline of the West* was translated into Arabic and gained currency among the reading public.

## CULTURAL DEVELOPMENT

The twentieth century may be divided into several phases in terms of the cultural development of Lebanon, Syria, and Iraq. The first third of the century can be regarded, to a large extent, as a continuation of the process of what is generally termed as the Arab literary revival (*al-nahda*), which started in the previous century and assumed the double role of reviving medieval or classical Arabic works of science and culture while translating Western works into Arabic and adapting new forms of Arabic culture, through translation, to Western norms.

Until the beginning of the twentieth century, traditional Arab cultural content included literary genres such as poetry, the revived classical *maqama* (rhythmic prose), *al-tarajim* and *al-siyar* (biographies). From the mid-nineteenth century and under the influence of Europe, a new Arab cultural life began to flourish. Although some older genres survived, others started to weaken or fade away. Some were revived for a short period of time like the *maqama*. Concurrently, other Western genres started to gain ground

such as the novel (*al-riwaya*), the journalistic essay (*maqala*), the short story (*al-qissa*), and theatrical plays (*al-masrah*).[5] But it was after the third decade of the twentieth century that these other genres dominated cultural life in Syria, Lebanon, and Iraq.

Inevitably, this interaction between the Western and local cultures did not express itself uniformly in all three Arab countries under study here. Thus, it is important to point out that the virtually land-locked Iraq, turned toward Iran and the Persian Gulf, lagged behind Syria and Lebanon, which were more exposed to Mediterranean influences and were, in a sense, more culturally 'advanced' than their Eastern neighbour.[6] Moreover, because of the immigration of many Syrian and Lebanese intellectuals to Egypt in the nineteenth and early twentieth centuries, there existed what we may term a common cultural axis that ran from Egypt to Lebanon, Syria, and, to a lesser extent, Iraq. It is, in fact, possible to suggest that these countries belong to one cultural sub-region until the present day. This is significant because it suggests that different Arab local cultures did not only interact with the West, but with each other as well, forming a number of regional Arab sub-cultures with shared features.[7]

## Science and technology

The scientific development in the specific areas under investigation (Syria, Lebanon, and Iraq) and in the whole Arab world in general during the twentieth century was unfortunately meager. Scientific and technological research and application were not properly funded and although some of the nationals of these countries did make some important contributions in some scientific fields, they were usually accomplished by émigrés working in Europe or in the United States. One opinion voiced in the middle of the century stressed that even if the term 'science' was enlarged to include the social sciences, the region was surely in a sorry state.[8]

## Education

One important indicator worth mentioning here is the level of education and research. According to last available statistics of 1995,[9] the gross percentage of enrolment rate of students of primary education age who attended primary schools was 109 per cent in Lebanon and 101 per cent in Syria. Unfortunately, statistics for Iraq are unavailable. These percentages become more meaningful if we compare them with the statistics for the Arab region as a whole (83.8 per cent) and for Europe (106.7 per cent) and the world (99.6 per cent). Secondary education enrolment reached 24 per cent in Lebanon and 17.9 per cent in Syria, in comparison with 12.5 per cent for the whole Arab region, 47.8 per cent in Europe and 16.2 per cent for the entire world. Tertiary education levels were 27 per cent in Lebanon and 17.9 per cent in Syria, in comparison with 12.5 per cent for the whole Arab region, 47.8 per cent in Europe, and 16.2 per cent worldwide. The breakdown of tertiary education by subject matter is as follows: in Lebanon, 26 per cent humanities, 52 per cent law and social sciences, 17 per cent natural sciences (including engineering and agriculture), and 3 per cent in medical sciences; and in Syria, 21 per cent,

35 per cent, 29 per cent, 11 per cent, respectively. The science and technology output is measured by the number of papers published in international journals from 1990 to 1995: 471 for Syrians, 500 for Lebanese, and 931 for Iraqis.

Despite the great variety among the countries, uniform developmental trends can be identified: i.e. increases in population, urbanization, and rationalization. Moreover, the salaried middle-class element plays an important role in all three countries. But while this development led to a radical social change in Syria and subsequently in Iraq, around the middle of the century when the middle classes of those countries took control of the state and declared its intention of ending superficial decolonization, the change was more gradual in Lebanon, which did not wish to tamper with the free economic market system.

Naturally, these developments were reflected in the cultural sphere. In Syria and Iraq, theatre flourished under the auspices of the state, while in Lebanon theatrical activities were promoted through private initiative. But in all three countries the theatre was influenced by a variety of Western theatrical schools. Similarly, Western trends influenced the field of painting in these countries.

During the same period, new types of literary forms emerged, such as the existentialist and the feminist novel, both of which brought to the forefront the two topics of the destiny of the emancipation of the individual and of women. In Lebanon, writer Suhayl Idriss promoted the existentialist movement, and his female compatriot Leila Baalbaki is considered the country's foremost feminist novelist.

The revolutionary period was the focus of narrative texts as well a new type of Arabic poetry whose value remains a subject of debate in literary circles. Iraq found its vanguard role in presenting a new form of modern poetry that was started by the school of Badr Shakir al-Sayyab (1926–1964). What was most impressive about al-Sayyab's poetry is that it blended modernity with rhythm. In the early 1960s, the periodical magazine *Shi'r* (Poetry) attempted to promote another school of unrythmic poetry that enjoyed ephemeral success in Lebanon.

## POST-1967

The overall cultural picture in these countries changed to a great extent after a second Arab defeat in the 1967 war with Israel. The new ruling class as well as the West were blamed for this turn of events. Directly after the war, the perennial issues resurfaced: independence and the preservation of local identity in face of Western culture and power. Expressed more eloquently, 'now in order for the Arabs ... to remain themselves while joining the industrial world that surrounds and beleaguers them from within, they would have to impress the rhythm of their material advancement upon all their other modes'.[10] From this concern, a more leftist and radical trend emerged, but it was not long before it produced its more powerful antithesis: a right-wing trend that found no outlet in the different modern cultural venues like the theatre, the novel, and poetry, but rather revived the conservative part of classical religious literature popularized in numerous newspapers and magazines of the early 1970s. Unlike the modernist Islamic trend at the beginning of the century, it revealed a more self-centred anti-modernist orientation whose main concern was preserving Islamic identity in a variety of fundamentalist forms. This trend is still very active, but it lost its earlier vigour. Today, it is impossible to identify any single cultural tendency that carries a well-defined message. The countries under discussion, like many other Arab countries, are passing through a cultural dilemma the results of which are difficult to predict.

In conclusion, it is evident that the last quarter of the twentieth century was not especially favourable for this region. Lebanon endured a civil war (that had regional dimensions) from 1975 to 1990. Iraq was entangled in a bloody war with Iran (the so-called First Gulf War) that lasted throughout the 1980s. Iraq's economic and political differences with the US and neighbouring Kuwait led to its invasion of the latter in 1990. This led in turn, in 1991, to the Second Gulf War, led by an international coalition headed by the United States and the United Kingdom which drove Iraqi troops from Kuwait and imposed a strict regime of sanctions that was still in effect in 2003 when the US and a few allies launched a full-scale attack on Iraq with a view to eliminating Saddam Hussein, based on the pretext that he was stockpiling weapons of mass destruction. At the present time, the situation in a wartorn and occupied Iraq is far from resolved. Clearly, the political and military situation in both Lebanon and Iraq had a negative impact on their cultural and scientific scenes.

It is noteworthy, however, that some signs of revival started to emerge at the end of the century in the fields of art. In Lebanon and Syria the novel was established as the most important genre of cultural expression. The new Lebanese novel, represented by many intellectuals, dealt with the experience of the civil war, while the Syrian novel, whose most prominent spokesperson is Hanna Mina, continued to focus on social affairs.

## PALESTINE AND JORDAN

---

### *Ali Mahafzah*

Before the nineteenth century, Palestine and Jordan did not pursue modern scientific disciplines, such as natural and applied sciences. In both areas, education was confined to the *kuttabs* (primary schools), which were housed in mosques, churches, Muslim, Christian or Jewish schools. Beginning in the second half of the nineteenth century, modern education was introduced through foreign missionaries and subsequently by the Ottoman Empire.

Since the creation of the British Mandate in Palestine, two systems of national education based on language and race developed independently of missionary schools. Since educational opportunities were mainly concentrated in the cities, rural areas were largely deprived of modern schools. Compulsory education was non-existent, which led to growing illiteracy among the Arab population. Arab education, it should be noted, did not aim to serve economic and social development, and there was a very limited interest in developing vocational education. The authorities in power used general education as a means of producing compliant government employees for the mandate authorities. The most significant Arab higher educational institutions during the mandate were the Government Arab College (Teachers Training College), the Women Teachers Training College, and Rashidiyyah Secondary School (later College) in Jerusalem, the Women Teachers Rural Training College in Ramallah, the Trade School in Haifa, and Kadouri Agricultural School in Tulkarem. The Jewish educational system was supervised by the Jewish Agency, which established its own curricula and programmes that endeavoured to fulfil the aspirations of the Zionist movement and were free from any supervision or control by the mandate government. Thus it must be concluded that the education available to Arabs failed to prepare them for practical life.

In Jordan, which came under the rule of the Arab government in Damascus from 1918 to 1921, the number of government schools was increased to 20 primary and elementary schools. This number continued to rise under the Arab regime in power before the British Mandate (1921–46). In the 1922/23 academic year, there were 44 government schools; by the end of the British mandate (1946/47) a total of 77 schools were operating. The number of students during the same period rose only slightly: from 3,316 to 10,729. Private schools increased from 33 in 1925/26 to 100 in 1938/39. The Arts and Crafts and School was Jordan's only vocational school.

After the first Arab-Israeli War (1948–49), the West Bank was integrated into Jordan while the Gaza Strip remained under Egyptian military administration. Under the Jordanian-Palestinian period (1950–67), there was a rapid growth in the number of schools. In 1950/51, there were 402 schools, 319 for boys and 83 for girls, with a total student enrolment of 65,793 students. In 1966–1967, the number of schools rose to 1,532, some 900 of which for boys and 632 for girls, with a total student enrolment of 302,668.

As a result of the Arab-Israeli War, about 500,000 Palestinians were forced out of the cities and villages by the Israeli occupation forces and became refugees in the West Bank, Gaza Strip, Jordan, Lebanon and Syria. The United Nations Relief and Works Agency for Palestine Refugees in the Near East (UNRWA) was created on 8 November 1949 to take care of these displaced populations. The students receiving their education at UNRWA-sponsored schools totalled 42,122 in 1950/51. This number steadily grew to 181,347 in the 1965/66 academic year. In the same year in Jordan, the number of students enrolled in UNRWA schools totalled 106,268 or two thirds of all refugee students. UNRWA also established a male teacher training institute at Shu'fat, a suburb of Jerusalem, in 1956 and another for female teachers in Nablus. Three vocational training institutes were also established in the West Bank and two in the Gaza Strip. In 1967, UNRWA schools in Jordan rose to 734, while schools in the in the Gaza Strip numbered 577.

Vocational education with its various industrial schools witnessed considerable development on both banks of the River Jordan. The total student enrolment in these schools rose from 148 in 1960/61 to 775 in 1966/67. The number of students enrolled in vocational training centres increased from 37 in 1960/61 to 262 in 1966/67. Agricultural education in Jordan started later than in Palestine. Commercial education on both banks of the River Jordan was first implemented in 1952 in Amman and Nablus. Commercial courses were created in the other cities of the kingdom during the 1950s. The student population rose from 26 in 1952/53 to 1019 in 1966/67. The first university in the kingdom of Jordan was established in 1962.

In 1967, the whole of Palestine fell under Israeli occupation, and Israel opened its borders to unskilled highly paid labour. Palestinian youths rushed in the thousands to this prosperous labour market, owing to their poor economic

conditions under Israeli occupation. As a result, learning and education lost status in the eyes of the young Palestinian university graduates, who faced serious unemployment problems. Thus students began to drop out of school and university and join the Israeli labour market. At the same time, the Israeli occupation forces imposed laws and regulations including charging high school fees and banning many Arabic school textbooks. Israel frequently closed schools and universities and arrested many teachers and students.

Despite Israeli restrictions, government schools in the West Bank and the Gaza Strip totalled 1,084 in 1994–95, including 15 vocational secondary schools. UNRWA supervises six vocational training centres. There are also 18 community colleges (or intermediate university colleges) in both territories, which trained 4,110 students in technological courses in these colleges. There are eight universities and four university colleges with a total student population of 15,632 at the Bachelor degree level, and 945 students pursued graduate studies in the 1998/99 academic year.

In Jordan, after the occupation of the West Bank, the number of students in 1967/68 totalled 192,931 and rose to 982,429 in the year 1999/2000 including 32,764 students in vocational training. In 1999/2000, Jordan could boast eight state universities and eleven private ones. The total student enrolment was 105,813 undergraduate students and 6,670 graduate students. Community colleges totalled 51, including 28 government and 21 private colleges in addition to two UNRWA colleges and three nursing colleges.

With regard to culture, printing presses and newspapers appeared in Palestine during the nineteenth century (e.g. the Franciscan Press, the Roman Orthodox Monastery Press, the Armenian Press and the English Missionary Society Press). These printing presses multiplied during the British Mandate. The Jewish community had its own Hebrew presses, while the Arabs and the British administration operated presses in their respective languages. During the Jordanian-Palestinian period, the number of Arabic presses rose, while a number of Arabic presses continued to operate under Israeli occupation. Arabic presses numbered 98 between 1914 and 1984.

*Al Quds al-Sharif*, the first newspaper published in Palestine, dates back to 1876. It was the organ of the Ottoman ruler of Jerusalem, or *mutasarifiyah*. In the same year the newspaper *Al-Ghazal* was founded. Between 1908 and 1918, some thirty newspapers came into existence. In Jordan, the newspaper entitled *Al-Sharq al-Arabi* appeared in 1923 as a governmental organ whose name was later changed to the *Official Gazette of the Emirate of Transjordan*. But the first daily newspaper in Jordan was published in 1927 under the name of *Al-Urdun*. Subsequently, other newspapers came in succession, bringing the number to ten in the year 2000, when the West Bank and Gaza Strip claimed the same number of Arabic newspapers.

Professional associations and cultural unions spread throughout Palestine and Jordan. The Palestine Students' Union was founded in Egypt in 1959. It was followed by the Palestine Workers General Union, established in Gaza in 1963. The Palestinian Women General Union, was inaugurated in 1971, the Palestinian Teachers General Association in Damascus in 1972 and the Palestinian Engineers General Federation in Baghdad in 1973. Some twenty-eight Palestinian literary and cultural leagues were

created between 1914 and 1984. During the same period, 163 cultural and sports clubs opened in Palestine.

Palestine has nine research centres: the Research and Documentation Centre at al-Najah National University (1972); the Documents and Research Centre at Bir Zeit University (1976); The Arab Intellectual Colloquium Society in Jerusalem (1977); the Rural Studies Centre in al-Najah National University (1981); the University Graduates League Research Centre in al-Khalil (Hebron) (1982); the Islamic Research Centre in Jerusalem (1985); the Palestine Liberation Organization (PLO) Research Centre; the Palestinian Studies Foundation (1963) and the Arab Studies Society in Jerusalem (1980).

Numerous poets and writers were active in Palestine during the twentieth century. Among the most prominent are Ibrahim Touqan, Abdul-Karim al-Karmi, Youssuf al-Khatib, Ishaq Musa al-Husseini and Akram Zu'aytir. Among the leading Palestinian historians are Bandali Jozy, Abdul-Latif Tibawi, Nabih Amin Faris, Nicola Ziyadeh, Irfan Shahid, Hisham Sharabi, Anis Sayegh, Mahmoud Zayid and Kamil al-Asali. Public and private libraries existed in Palestine on a large scale throughout the twentieth century. Palestine possessed forty-eight libraries during the British Mandate. During the Jordanian-Palestinian period, five public libraries were opened by the municipalities of major cities in the West Bank. Under Israeli occupation, however, importation and circulation of 5,410 books was banned between 1967 and 1985. This led to a decrease in the number of publishing houses in the West Bank from twenty-three to four.

Applied arts also appeared in urban as well as rural areas in Palestine during the twentieth century. Urban artists practised engraving, decoration and calligraphy, while in rural areas tattooing, embroidery and weaving were widely practised. In addition, many Palestinian craftsmen reproduced icons for sale to local monasteries and foreign visitors. A number of outstanding Palestinian painters gained prominence in the course of the century: Ismail Shammut, Sophie Halabi, Naheel Bisharah, Paul Gerogsian, Abdullah Ni'wash, Fathi Ghaban, Jumanah al-Husseini and Naji al-Ali. Sculpture in Palestine was influenced by principal Arab and foreign artistic movements. Eminent sculptors include Abdul-Hayy Musallam, Mustafa al-Hallaj, Muhammed Bushnaq and Nazik Ali Ammar.

As for popular folkloric arts and traditions, the Palestinians have developed beliefs, customs and traditions related to betrothal, marriage, birth and child raising. The Palestinian cultural heritage also comprises numerous folkloric dances, rhythmic clapping, Sufi (dervish) dances, solo and collective popular songs performed by women. Since the 1930s, Palestinian musical bands have appeared featuring string musical instruments (rebec, lute), wind instruments (clarinet, double-barrelled flute and other types of flutes) and percussion instruments (castanets, drums, tambourines, kettle drums, and tabors).

Jewish colonizers produced the first propaganda films in Palestine in 1912, and such films continued throughout the 1930s and 1940s. During the British Mandate, new motion picture houses opened for the screening of Egyptian commercial films. During the Jordanian-Palestinian period, film production ceased. Documentary films about Palestine and the Palestinian question outside Palestine appeared in 1968: fifty-three such films were produced between 1970 and 1984.

Since the creation of Transjordan in 1921, Jordanian writers explored various literary genres, including the short story, the novel, poetry, journalistic articles, literary criticism, children's literature, while studies and research developed. The court of the monarch Abdullah ibn al-Hussein I provided a congenial meeting place for Jordanian and other Arab poets and literati. Among the prominent literary figures were King Abdullah himself, Mustafa Wahbeh al-Tal, Abdul-Munim al-Rifai, Abdul-Halim Abbas, Husni Fariz and Rashid Zayd al-Kelani.

Popular mores and traditions in Jordan's rural and urban areas were nearly identical to those in Palestine. Jordanian painting developed in the 1960s through the efforts of artists such as Rafiq al-Lahham, Mouhanna al-Durrah and Princess Wijdan Ali. To promote artistic movement in the kingdom, the Department of Culture and Fine Arts was established in 1966, followed by the Jordanian Royal Foundation of Fine Arts and the Fine Arts Institute. Members of an artists' union established in 1978 exhibited their works in Jordan and abroad. Noteworthy sculptors include Muna al-Saudi and Karram al-Nimri. Khalid Khrays works in the medium of lithography, while Farouq Lambaz and Mazen Asfour are renowned for their collages and Rabah al-Sghayyir, Jalal al-Refai, Mahmoud Sadiq and Emad Hajjaj are considered the country's most famous caricaturists.

Distinguished by its rural Bedouin character, Jordanian music constitutes an ancient cultural heritage. With the creation of the Jordanian Broadcasting station in Amman in 1959, popular songs were performed with string instruments rather than on the traditional instruments such as the *shibbabeh* (flute), *mijwiz* (double-barrelled flutes), tabor and rebec. Progressively, Western musical instruments were also introduced. Jordanian music gained wider exposure thanks to the programmes of the Jordanian Television (JTV), which was founded in 1968. The Jordanian Musicians League was established in 1980, and the Jarash Annual Festival inaugurated in 1981 further contributed to the promotion of Jordanian music particularly in the Arab world. Since 1992, several Jordanian music festivals have been organized. According to official estimates, approximately 200 Jordanian singers and over 30 musicians work in a professional capacity. A faculty of fine arts was established in Yarmouk University in the early 1980s and the National Musical Conservatory was established in collaboration with the Noor al-Hussein Foundation. In addition, the Jordanian Academy of Music opened its doors in 1990. One of the largest of the ten orchestras active in Jordan in 2000, the Jordanian Armed Forces orchestra, founded in 1977, boasts 120 performers.

In the field of cinema, motion picture houses first appeared in Amman in the 1930s and spread to other Jordanian cities over the next two decades. The first Jordanian-produced film was premiered in 1948, and in 1957 the film entitled *Sira' fi Jarash* (Struggle in Jarash) was produced by the Jordanian film production company.

The creation of the country's first theatre association in Irbid in 1945 marked the earliest attempt to promote Jordanian theatre. However it was not until the foundation of the Jordanian Theatre Family in 1962 that theatrical arts began to flourish.

In the last three decades of the century, cultural activity has increased thanks to the efforts of such organizations as the Jordanian Writers Union, the Jordanian Writers League, the Royal Academy for Islamic Civilization Research (Al-Bait Foundation) (1981), the Arabic Language Academy (1977) and the Arab Thought Forum (1981), as well as dozens of cultural forums and research centres operating under the auspices of universities, and numerous privately operated independent cultural institutions and associations.

# 34.6

## THE GULF COOPERATION COUNCIL
## SAUDI ARABIA, KUWAIT, BAHRAIN, QATAR, UNITED ARAB EMIRATES, OMAN

---

*Mariam Lootah*

The six countries examined in the present sub-chapter are the members of the Gulf Cooperation Council (GCC), a body established in 1981 in the face of various external threats (e.g. the overthrow of the Shah of Iran, the Soviet invasion of Afghanistan and the outbreak of the Iran-Iraq conflict) to ensure regional security and stability for its highly strategic oil-producing member states. According to the organization's stated purpose:

> while, on one hand, the GCC is a continuation, evolution and institutionalization of old prevailing realities, it is, on the other, a practical answer to the challenges of security and economic development in the area. It is also a fulfilment of the aspirations of its citizens towards some sort of Arab regional unity.

### SAUDI ARABIA

The alliance of the strict Islamic sect known as the Wahhabi and the Saud tribes determined the contemporary history of the Arabian Peninsula and played a crucial role in the establishment and the continuity of the Saudi Kingdom. The Saudi state was founded in 1726 even though the peninsula officially remained under the control of the Ottoman Empire.

At the end of the First World War (1914–18), which marked the demise of the Ottoman Empire, the geopolitical map of the Arab World (or Middle East) was redesigned by the colonial powers: Syria and Lebanon fell under French influence; Palestine, Iraq, and the Arab Peninsula were placed under British control. However, by the end of the Second World War, American influence in Saudi Arabia had grown rapidly. American oil companies controlled Saudi oil production, and the Saudi Kingdom became America's closest ally in the region after Iran.

With the discovery of oil in the 1930s, the country witnessed some economic development and modernized its major cities, but the Wahhabi-Saudi coalition, regarded as the bedrock of power, impeded social and political progress, particularly as regards the status of women and the basic civil liberties. To this day, almost all significant cultural activities are restricted. The participation of women in economical, cultural and social life is limited. During the twentieth century, Saudi Arabia remained a closed society.

The war of liberation of Kuwait from the Iraqi occupation (1990–91) followed by the Anglo-American invasion of Iraq (March 2003) has shaken the status quo in the Gulf States, particularly Saudi Arabia. Political and cultural stagnation in the Saudi society have created a state of general discontent in the country, a favourable ground for the emergence of clandestine political organizations. Yet, the increased American military presence contributed to the emergence of extremist Islamic movements, such as al-Qaida. In the present context, even the near future of the Saudi Kingdom is difficult to predict. But it is almost certain that the absence of serious democratic reforms will create social and political unrest and pave the way for general instability.

### KUWAIT

Kuwait gained its independence from Britain in 1961. Among the factors that have contributed to Kuwait's instability over the last four decades of the twentieth century are geopolitical and territorial issues, the country's relatively small population (750,000 persons, 2 million including expatriates), the lack of a strong national identity, and Kuwait's vast oil reserves. Despite these difficulties, the traditional gap between the people and their rulers has been bridged by introducing a certain degree of national dialogue in the political processes. The first *majlis*, or consultative council, was created in 1921.

With the arrival of King Ghazi in Iraq in 1938, Baghdad claimed that Kuwait was part of Iraq's Basra region to the south. In the same period (1938–39), oil was discovered for commercial exploitation, and Britain intended to ensure that Kuwait would remain under its sphere of influence and independent from Iraq. In 1938, the newly elected *majlis* recognized the power of the members of the Parliament. As Kuwait increases the political participation of its people, it will reinforce the country's national and cultural identity; however it is believed that Kuwait's traditional non-constitutional political system cannot continue indefinitely.

## BAHRAIN

The Emirate of Bahrain occupies an archipelago in the Persian Gulf that has been inhabited for over 6,000 years. The capital of the Kingdom of Bahrain today is Manama. Bahrain's contemporary history is marked by the early emergence of reform movements in the country. The first movement, created in 1923, stressed two essential points: the establishment of a Majlis Shūra (Consultation Council), and the end of the British influence in the country. By supporting this position, Bahrain's ruler, Sheikh Issa Ben Ali al Khalifa, was removed from power.

This first reform movement was followed by a second (in 1938), and a third more effective wave of reform in 1945. Known as the National Union Committee, this latter movement led to more elaborate reform programmes that highlighted the importance of national unity. Abdel Rahman al Baker in collaboration with Abdel Aziz al Shamlan headed the National Union Committee. The movement's success is attributed to the fact that, unlike the two earlier attempts at reform, it won the support of the Shiites and Sunnites communities within Bahraini society.

Bahrain gained independence from Britain in 1971, yet the British continue to exert considerable influence on the country. The rise of Sheikh Hamad al-Khalifa to power after his father's death in 1999 marked a new era in Bahraini history. In 2002, Bahrainis elected members of the lower house of Bahrain's reconstituted bicameral legislature, the National Assembly.

## QATAR

Qatar, a small country with a very recent history, has a population of about 60,000 native Qataris and over 300,000 expatriate workers. The contemporary history of Qatar was marked by the rise to power of Sheikh Hamad bin Khalifa Āl Thani by the 1995 *coup d'état* against his father. An ambitious man, his agenda calls for political reforms, the establishment of a national parliament and the writing of a constitution.

Some social reforms concerning the participation of women in the public life had been undertaken, as evidenced by the fact that women have been appointed to high-level public positions. However, in exchange for the support of the United States, the Sheikh was forced to allow the Americans to install a military base in Doha and to play a role in Qatar's domestic and foreign policies.

## UNITED ARAB EMIRATES

The United Arab Emirates (UAE) is a federation of seven emirates: Abu Dhabi, Dubai, Sharjah, Ajman, Umm al-Qaiwain, Ras al-Khaimah and Fujairah. The rulers of the Emirate of Ras al-Khaimah, the Al-Qawasim tribe, owned the region's considerable naval force and stood up to British acts of aggression for more than half a century. In 1819, the British invaded Ras al-Khaimah, the historic capital of the Al-Qawasim, destroying much of their naval fleet, and imposed the treaty of 1820, which marked the official beginning of British colonization of the emirates (formerly known as the Trucial States). Agreements with the British required the al-Qawasim fleet to halt all maritime activity including fishing, and subsequently the fleet was completely destroyed.

Between 1820 and the opening decades of the twentieth century, time seemed to stand still in the region. In 1936, a reform movement emerged in the Emirate of Dubai and resulted in the election of a *majlis* among the notables. Some administrative and educational reforms were initiated as a result, but this promising undertaking failed after six months owing to British intervention.

Oil was discovered in Abu Dhabi in the 1960s, and the bulk of the oil revenues were spent on building state infrastructures. In 1971, the seven emirates united to form the present federation. However, the country's poorly planned development resulted in negative setbacks in respect to social and cultural issues. The Emirates currently face a problem that threatens the identity and security of society: the country's great demographic imbalance. The overwhelming majority (approximately 85 per cent) of the population are expatriate workers, most of which are not of Arab origin. The three challenges facing the Emirates today are security, the safeguarding of national identity and democratic reforms.

## OMAN

One of the world's foremost maritime nations, Oman served as an important link on the trade routes between Mesopotamia (present-day Iraq) and India and China. From the eighth century, a minor school of Islamic thought, known as the Ibadit School, ruled Oman for more than one thousand years and instituted a highly original political system, the Imama. Unlike the major Islamic branches, Sunni and Shiite, the Ibadits categorically rejected the hereditary system of power, adhered to the principle of Shura, consultation, and the free election of the political and religious leader or imam. This principle introduced a theoretical base for democracy in Islamic political thought and has also served to consolidate the national political culture of Oman

Beginning in the second half of the eighteenth century, the British presence and influence grew rapidly. The powerful Omani fleet was destroyed along with that of the Trucial State (present-day United Arab Emirates). Between 1900 and the beginning of the rule of Sultan Qaboos bin Said in 1970, Oman had practically disappeared from the international scene. The sultan has undertaken remarkable political, economical and cultural reforms, which has enabled Oman to strengthen its rich cultural and historical traditions. Since the 1970s, Oman has played an active role in Arab affairs and on the international scene thanks to its pragmatic foreign policy.

## CONCLUSION

The major external and internal factors that have marked the region through its long history are the tribal structures, religion, British colonization and the discovery of oil.

Even though not all of these Gulf States developed along the same lines politically, owing to specific domestic, regional and international circumstances, it is clear that there are many similarities concerning the manner in which they were established. Nonetheless, it must be noted that

socio-economic development has not been accompanied by political and, above all, democratic reform.

# 34.7
## EGYPT

*Anouar Abdel-Malek*

Contemporary Egyptian society and culture can best be understood in the context of the re-emergence of Egypt after four centuries of marginalization and decline. This renaissance occurred as the result of the vision and decisive leadership of Muhammad Ali in the first half of the nineteenth century, precisely when Egypt faced relentless penetration by foreign investment, which paved the way for British occupation (1882).

## MUHAMMAD ALI

From the onset, Muhammad Ali clearly defined his historic goal: the creation of a modernized Egyptian society and state in order to achieve the revitalization of the Islamic heartland. For Muhammad Ali, modernization meant endowing the state with its own army, a state-owned industrial base and a system of modern education inspired by the European achievements from the Renaissance to the age of revolutions (scientific, industrial, political) and with an overall vision of national culture. This was achieved thanks to the creative energies of Ibrahim Pasha and Rifaa al-Tahtawi, with the support of devoted European (mainly French) experts. By 1830, Egypt had created an advanced industrial state-owned sector and the most powerful modern army outside Europe. Owing to the vision of Tahtawi, the state and society had access to an extensive network of highly trained cadres in all major fields of activity, while progress in education continued, mainly under Ali Mubarak. Starting with the adoption of selected achievements of French society during the Napoleonic era and its aftermath, Tahtawi resolutely oriented national cultural policy towards national unity and social progress as expressed in his motto: 'May the place of happiness for all of us be Fatherland, which we shall build with liberty, thought and industry!'

It took the coalition of all major European states to compel Muhammad Ali to dismantle his protective economic shield. Thus, the London Convention (1840) stifled Egypt's well-advanced modernization programme – the very process that the Japanese Emperor Meiji chose to study in 1868 upon his rise to power.

Between 1840 and 1881, European financial intervention, facilitated by the building of the Suez Canal, led to gradual hegemony of foreign powers over the Egyptian economy. The first Arab-elected parliament coincided with the formation of a vigorous private capitalist sector under Ismail (1867–79). In the upsurge of the national and democratic movement, a second stage of the Egyptian renaissance developed under the influence of Nadim, Baroudi and military figures Arabi and Ebeid. The 1881 Revolution provided the pretext for the British invasion, leading to the occupation of Egypt in 1882. The British occupation put the clock back in the political, economic and cultural fields but did not affect the vital transport infrastructure that ensured the export of cotton. While social development could not proceed towards the creation of a national bourgeoisie, education had to bear the brunt of Dunlop's vicious restrictive policy.

Facing the oppressive measures of the occupying power, several significant developments arose. The wealth of the Egyptian upper classes depended on the growth of dependent agrarian capitalism. On the cultural front, the press – under the converging efforts of Arab intellectual émigrés who sought refuge in Egypt from the 1870s and joined forces with the heirs of Nadim (mainly from the National Party of Mustafa Kamel and Mohamed Farid) – nurtured the upsurge of the national movement towards independence, constitutional government and economic progress.

From the reign of Muhammad Ali until the revolution of 1919, Egyptians had to consider the crucial questions: What is the cause of the decadence, and how can a revival or renaissance be achieved? Two major orientations emerged. The liberal modernist approach, inspired by Tahtawi, from 1820 onwards held that the selective assimilation of the European experience within the context of national sovereignty was the preferred path. A second orientation was to emerge decades later during the period of foreign intervention: the Islamic fundamentalist approach inspired by Mohamed Abdoh (1849–1905) held that to avoid the increasing decadence it became imperative to revive the fundamental principles of Islam: monism accompanied by justice.

# EMERGENCE OF CONTEMPORARY EGYPT

Thus, the stage was set for the emergence of contemporary Egyptian society and culture. The revolution of 1919 contained the seeds of both moderate national liberalism and radical populism. The overall balance of forces during the British occupation led to the emergence of the first option: the 1923 Constitution eventually granted to the Wafd (the Egyptian Nationalist Party) defined Egypt as an independent kingdom in the lineage of the dynasty of Muhammad Ali, while the military occupation proved that the protectorate had not ended. The radical option, as represented by the Wafd's secret organization (Abdel-Rahman Fahmy), was dismantled to the benefit of the official Wafd led by Saad Zaghloul and his supporters.

The year 1923 marked the beginning of the liberal modernist age, now rehabilitated, during which the foundations and formative institutions enabled the major schools of thought and action to promote the revitalization of Egyptian society and culture, which represented the first major stage of Egypt's national project in the twentieth century.

The basic economic structure remained, i.e. an essentially capitalistic agrarian economy. However, the rise of the urban middle classes opened new paths. From the onset, Talaat Harb's call for 'an Egyptian bank for all Egyptians' indicated that the new emerging classes intended to assume a role independent of the foreign investors. The foundation of the Misr Bank (1923) paved the way for the Federation of Egyptian Industries and the broad network of industrial and commercial institutions of the Misr group during the 1930s, whose activities ranged from textile to air transport and cinema. By the mid-1930s, the balance within the capitalist class began to shift, from the agrarian landowners (the 'feudal' sector) to the modern banking-industrial groups. New political forces emerged around the Wafd: the liberal-constitutionals and Saadist parties represented the big landowners and the industrial groups respectively. On the left wing were the communist and socialist parties, and these new radical forces competed with the traditional political establishment: Ahmed Hussein's Young Egypt, the New National Party, and the Muslim Brotherhood. The stage was thus set for a new national and social revolution.

In the midst of this bustling socio-economic evolution, culture and intellectual activity could hardly remain stagnant. The period between 1923 and 1952 can be defined as the 'golden age of liberal modernism', which precipitated in-depth transformation. The economic, social and political crises, and the resulting tensions and contradictions, led to serious repercussions in the realm of thought and culture. Each of the two major tendencies that took shape during the nineteenth century splintered into conservative and radical wings. The liberal modernist tendency was divided between a conservative wing, bringing together the minority parties concerned with social stability and the imitation of Europe, and a radical wing, which combined the goal of national liberation and independence with the demand for radical economic and social transformation as sought by the left-wing progressive parties, the youth movement and elements of the new national parties.

During this period of modern liberalism the main institutional basis for socio-economic progress and cultural renaissance was created. Thus, Fuad al-Awwal (now Cairo) University was founded as the centre of a network of scientific and specialist bodies including the Egyptian Geographical Society, the Royal Egyptian Agricultural Society, the Institut d'Egypte, the Egyptian Society for Statistical and Juridical Sciences, the Société des Amis de l'Art. Myriad organizations emerged during this period: the Egyptian national press (*Al-Ahŕam, Al-Mokattam, Al-Hilal, Sawt el-Umma, Al-Misrî, Al-Masawwar*), the Misr Bank group, the Federation of Egyptian Industries, the universities of Alexandria and Aïn Shams, publishing houses (e.g. Dar al-Maaref, Dâr al-Hilal), the Committee for Writing, the translation and publishing company Dar Nahdat Misr, and cultural periodicals such as *Al-Kâteb al-Misri, la Revue du Caire, Apollo*, and *Al-Rissalah al-Gadiidah*.

## THE ARTS

The period's exuberant economic, social and political activity fostered a burst of creativity in the fields of literature, the arts, philosophy, and natural and social sciences. This was the age of the emergence of the novel, which reflected the rise of urban centres in traditionally rural Egypt. Its major centres – Cairo, Alexandria, the Nile Delta cities (e.g. Tantah), Port Said – emerged as centres and settings for the Egyptian novel, although a certain rural flavour persisted. The initial strides made by Manfaluti, Ibrahim al-Mazni and Taha Hussein were taken to greater heights by Yehia Haqqi and Nagib Mahfuz. The younger novelists, led by Abdel-Rahman al-Sharqawi, belonged mainly to the progressive faction of the national liberation movement, while Ihsan Abdel-Qoddous' novels reconciled the romantic approach with the demands of the radical nationalists. The transition from the modernized traditional forms of the novel to a truly modern, incisive approach was the life achievement of Yussef Idris, widely considered the Egyptian Chekhov. To this day, the influence of Idris and Mahfuz contribute to the emergence of new perspectives for the Egyptian novel and short story. Both authors stand at the juncture of the liberal period and the age of radical transformation ushered in by the revolution of July 1952.

Among the principal exponents of modern trends are the poets Salah Abdel-Sabbour and Salah Jahine, and the playwrights Tawfiq al-Hakim and No'man Ashour. Similar advances in the field of music were achieved by Sayed Darwish, Om Kolthoum and Mohamed Abdel-Wahab. During this era, the thriving film industry generated more income that any other sector except the textile industry. Once again, the Misr group took the lead, promoting a generation of directors within the circle of Henry Barakat, who successfully adopted a romantic approach to social realism. The period's leading actors attained the level of Nagib Rihani, Yousef Wahbi and their disciples. Other noteworthy artists who shared this innovative movement include the sculptors Mahmoud Mokhtar, renowned during the 1919 Revolution, Gamâl al Segini and Adam Henein and the painter Hamed Abdallah. The Islamic fundamentalist tendency developed in two directions: the Muslim Brotherhood, founded by Hassan al-Banna in 1927, promoted traditional ideology among the peasantry and the urban and rural middle classes, via its organ

*Al-Da'wa*, while Sayed Qotb, representing the more moderate position, emerged as the leading theoretician. Abdel-Razzaq al Sanhouri made advances in the field of legislation on the basis of Islamic Shariah.

## NATIONAL REVOLUTION

The radical populist approach developed mainly in the political field, from the nationalist movement Misr al-Fatat, founded by Ahmed Hussein, and which gave rise to the Free Officers, the secret army organization founded by Nassar in 1952 for the purpose of overthrowing King Farouk I and liberating Egypt from Great Britain. It aimed at revitalizing the national movement in the pursuit of political and social goals. This became the message of the Free Officers six months after the Cairo fire of 26 January 1952, and the ensuing chaos under martial law, when the Free Officers took power, thus circumventing the united national front.

Under the leadership of Gamal Abd el-Nasser, Egypt underwent a national revolution (1952–64) followed by a social revolution (1964–70), which brought about the nationalization of the economy and the Suez Canal, followed by the war of attrition after 1967 that prepared the ground for the 1973 war. Under Anwar Sadat, the new economic policy launched in 1978 led to a general economic decline to the benefit of the new class of businessmen, mainly importers. The road to strategic development thus reached a bottleneck. Under Mubarak, attempts to limit the effects of globalization have proceeded with considerable difficulty.

The cultural field inevitably reflected these profound changes. During the early years (1952–67) until the October 1973 war, the liberal modernists witnessed the regression of their conservative sector and the rise of radicalism. Consequently, nationalism, anti-imperialism, Arab unity, and for a time socialism, came centre stage, while the Islamic fundamentalist faction gathered strength. From 1967 onwards, the rift between these two groups reached new heights. The 1967 military defeat weakened the national-progressive branch of the liberal modernists. Simultaneously, buttressed by the growing influence of the major oil producing countries, a wave of Islamic fundamentalism swept the population.

## AFTER 1967

Thus, the post-1967 period can be defined as the era of sociocultural conservatism and the growth of a populist Islamic movement, sometimes veering towards integrism, coupled with a parallel growth of Western-oriented modernization. The moderate position receded in favour of a rising wave of confrontations, fuelled by the Palestinian tragedy and related military interventions. As a result, a closer relationship developed between the two radical sectors of liberal modernism (nationalism) and Islamic fundamentalism (as distinct from integrism). While the liberal modernist current prevailed in the field of culture, the new novel, under the powerful influence of Nagib Mahfuz, was enriched by Gamal Ghitani, Son'allah Ibrahim and their peers. A new style of poetry combining romanticism with social realism emerged through the works of Ahmad Fuad Negm, Salah Jahin, Fuad Haddad, Ahmad Hegazi, Abdel-Rahman al-Abnoudi. Yet, theatre and cinema lagged behind owing to the overwhelming popularity of television. Nevertheless some important films were produced, such as Shadi Abdel-Salam's film masterpiece *Al-Momiaa (The Mummy)*, which exerted a great influence on his younger disciples. Alfred Farag pursued the social realist tradition in theatre, and Egyptian painting and sculpture reached maturity through the works of Hâmed Abdallah and Gamal al-Segini. The new Cairo opera house provided a suitable forum for music, opera and ballet.

In spite of a 50 per cent literacy rate, Egypt's school network and fifteen universities continued to grow. The fields of philosophy, geography and geopolitics, history, psychology and literacy criticism developed considerably thanks to such scholars as Abdel-Rahmân Badawi, Lonis Awad, Mahmoud Mandour, Gamal Hamdan, Galal Amin' Tareq al-Bishri, Mohamed Anis, Yousef Maurad, Mustafa Soueif, Mohamed Mandour, Ghali, Hakri and Ezzedhin Ismail. The groundwork in the field of Egyptian cultural history and philosophy had been laid by Sobhi Wahidah's philosophy, and Hussein Fawzi provided the chronological and general history of the national movement as documented by Abdel-Rahman al-Rafe'i.

From 1952 onwards, the role of the state grew in the field of culture education and the media. The state developed its dominance in education, while private and foreign institutions played a larger role especially at the university level. The newly created Ministry of Culture aimed at providing both a general orientation to cultural life and a network of institutions and activities capable of involving a large majority of aspiring intellectuals. The tremendous development of the mass media, and particularly television, occupied centre stage in public life. There was a rapid growth of information and creative thinking in the press. Soap operas proliferated on television after the era of social realism (1973–85), as the once-important Egyptian cinema declined.

From 1978 onwards, the impact of globalization was acutely felt in the spheres of economy, society, culture, and policy orientation in general. The values system of modern Egyptian society, deeply rooted in its long and illustrious civilization, suffered as a result of this process. The traditional collective spirit gradually gave way to individualism. The market economy revealed the predominance of imports and oil revenues. The effects, particularly the introduction of foreign global models, were felt primarily in the modern urban areas and eventually in the rural areas as well.

In reaction to this unprecedented transformation, Egyptian society and culture underwent a revival of national culture, deeply intertwined with its national and revival movements. Hence there emerged a confrontation between foreign penetration and the deep attachment to the Egyptian nation and its distinct identity. Thus globalization has prompted the resurgence of a desire to affirm a national identity as well as creativity in the sociocultural field.

The resurgence of the national dimension in the field of culture and in the society at large brought to the fore a hitherto unknown level of contradictions between the two major schools of thought in contemporary Egypt, i.e. liberal modernism and Islamic fundamentalism. The former,

bringing together the national radical and progressive schools of thought and action, felt that it was better to face globalization, while the Islamic fundamentalists considered that the deeply rooted popular culture would resist globalization. The growing polarization between the two schools was fostered by a complex network of regional and international influences that were foreign or inimical to the traditional centrist identity.

More recently there has been growing dialogue between large sectors of these two orientations, a process prompted by the rising tide of aggression from Suez to Palestine and Iraq. Proceeding from the pioneering socialist thought of Salamah Musa and Shohdi Attiyah, a new generation of national-radical political thinkers and experts emerged around Ahmad Bahâ Eddine and Mahmad Heykal. This new trend is also reflected in the modernist Islamic political writings of Tareq al-Bishri, Ahmad Kamal Abul-Magd and Selim al-'Awwa. In addition, a new generation of publishers and periodicals gave expression to this renewal. The General Egyptian Book Organization and the publisher Dar al-Shorouk collaborated with the previous generation of publishers and with influential periodicals such as *Al-Taliah*, *Woghat Nazar* and *Al-Fousoul*. The national democratic orientation as defined in the 1940s, particularly by the National Committee of Workers and Students, continues to provide inspiration for advocates of this trend.

More then ever, the question of identity has emerged in recent years. The crisis of the project for Arab unity gave rise to a search for a distinctly Egyptian identity with both Pharaonic and Islamic components. One-sided hegemony raises new questions about Egypt's cultural future: is Egypt proceeding along its pro-Western orientation? Or is it looking towards the East, consistent with its history and geopolitical context, as expressed in the Non-Aligned Movement of the 1950s.

## THE SUDAN

### *Saidou Kane*

**COLONIAL SUDAN:
THE CONDOMINIUM**

On the eve of the First World War, the Sudan region offered the occupying power several geostrategic advantages owing to its location among its neighbouring countries: Chad and the Central African Republic to the west; Libya and Egypt to the north; Kenya, Uganda and the Democratic Republic of the Congo to the south; and Eritrea and Ethiopia to the east. This pivotal position led to a strategy of occupation that took the form of the Anglo-Egyptian Condominium.

In 1914, the Sudan constituted a mosaic of peoples, subdivided (as they are at present) into distinctive geographic entities. The north was entirely Muslim – and for all practical purposes, a part of the Egypto-Ottoman world – whereas the centre was more mixed and dominated by Islamicized but not necessarily Arabicized populations. In the south (where traditional African religions remained strongly implanted) and in the central mountain regions lived pagan and Christian populations, including the Dinka (population: 2 million) and the Nuer (500,000), who led a nomadic existence in the basin of the Upper Nile and the Nuba (500,000), a farming people who occupied the central hills. While the Bagarra, a black pastoral people inhabiting the central regions and practising transhumance, are Arabicized today (although their numbers include some assimilated Fulani), this is not true of the nomadic Beja camel herders (population: 500,000) who inhabit the mountains flanking the Red Sea.

In the country's various agro-ecological zones, the subsistence economy, which is inseparable from the social structures, was underpinned by basic social structures characterized by endogamy. The human environment was organized according to permanent base villages.

In the north, traditional know-how in relation to food production, handicrafts and monumental art has survived. Upon their arrival in the region, the European colonists encountered irrigation techniques that predated those they would employ in the inter-war period for the development of the Gezira (the 1925 concession agreement). The Archimedean screw (*shaduf*), the *sāqiya* (a water wheel turned by animal traction) and irrigation by flooding the basins of the main branch of the Nile are age-old techniques, perennial irrigation being introduced by the British. Land tenure was largely personal (*mulk* in the region of the White Nile). Joint ownership was the rule as in other African agricultural civilizations in which only usufruct was allowed, the land itself being inalienable.

In order to avoid stirring up Muslim fanaticism, the British administration banned Christian missionaries from working in the north. It authorized such activity in the south, where the Christian churches set up primary schools using African languages and English for instruction.

Until 1939 the policy of indirect administration (Indirect Rule or Native Administration) enabled the administration to thwart popular uprisings, immobilizing the rich multicultural reality in fragmented localities. The new approach involved the recruiting of docile and apolitical intermediaries and the celebration of local cultures with the aim of restricting the influence of the urban elite, inhibiting its anti-colonialism and preventing its association with Egyptian pro-independence circles (1924). All northern influence was excluded from the south and vanished tribes were resurrected. Anthropologists (e.g. Evans-Pritchard) were set to carry out this work in the south. English was used in the south instead of Arabic, and the region remained cut off from the north until 1946.

At the outbreak of the First World War, the British exploited and aggravated the antagonisms between the different brotherhoods, setting Sayyid ᶜAbd al-Rahmān al-Mahdī (descendant of the Mahdi), the leader of the Mahdiyya, against Sayyid al-Mīrghanī, the leader of the Khatmīyya.

This situation helped to radicalize the struggle against the British presence, which was organized with the support of the Egyptian national movement, led by the Wafd party of Saᶜd Zaghlūl (1857–1927). This movement had close contacts with some members of the new Sudanese intellectual elite. An opposition movement in the army was crushed, and the Egyptian soldiers expelled.

The division of the country into a north where more respect was shown for the culture and a south wrenched away from its religious and cultural traditions would come to a dramatic climax in August 1955 with the beginning of a civil war that lasted 17 years.

## THE AGE OF THE NATION STATE

The emergence of a modern, independent Sudanese state was far from certain in view of the existence of conflicting trends of opinion that favoured, on the one hand, the union of Sudan with independent Egypt or, on the other, a separate identity for the country. The unilateral declaration by which the King of Egypt proclaimed himself 'King of the Sudan' in 1951 and granted the 'province of the Sudan' a certain degree of autonomy created serious problems for the entente between the British, Egyptians and Sudanese. This decision created unanimity against the union of the Sudan with Egypt. The British, in some difficulty, then endowed the Sudan with autonomous institutions, which swiftly proceeded to vote in favour of independence, which was proclaimed in January 1956.

The Sudan's major problem thereafter concerned its unity (the issue of southern Sudan), the nature of its state power (Islamist, since 1989) and the modernization of its political, socio-economic and cultural structures. The Sudan gradually developed education, the arts, science and culture and is increasingly giving women their place and paying greater attention to literacy education and the promotion of the press and media, even if, at present, these forms of social communication are almost entirely under the control of the state monopoly. The increasing use of the Arabic language also contributes significantly to communication and integration. However the status of the other national cultures has still not been properly re-examined.

## THE DEVELOPMENT OF EDUCATION AND WOMEN'S EMANCIPATION

The British administration trained many auxiliaries. In Khartoum, it established the Gordon Memorial College. The watchword was to avoid turning out 'intellectuals', who were 'a source of trouble'. This school would eventually become the University of Khartoum. At Omdurman, a school of Muslim law – the future university – was founded. It focused on a form of Islam without Mahdism. The modern instruction introduced by the British was theoretical. Nevertheless, it gradually developed into the main vehicle for social advancement and access to administrative positions. Since independence much effort has been devoted to increasing the number of schools and often teachers have become community leaders in the villages.

Education for females began more recently. A private college for women was set up just after independence, and girls were first admitted to the University of Khartoum in the 1959/1960 academic year. Since then, a university for women has been created. The role and place of Sudanese women may be measured by their degree of integration in the education system and the labour market. Their presence is most evident in the area of education, handicrafts and administration. They predominate in the health sector and are also represented in a majority in the liberal professions. Islamic law studies dominate the curriculum at Omdurman University, which admits students from the *khalwas*, the traditional Qur'anic schools. Two other universities have opened more recently, in Juba and Gezira, the latter being specialized in agricultural studies. The Khartoum Technical Institute offers university-level technology training. In 2001, the literacy rate in Sudan was 78.1 per cent, and education is free of charge. However, the civil war brought about the collapse of the school system in the south regions.

An Institute of African and Asian Studies, established after independence, has published a great deal of material on the history, sociology and daily life of people in the Sudan. The Arab Centre for Education, Culture and Science, which opened in 1977, is devoted to Arabic language and philology studies. The Sudan National Museum in Khartoum possesses collections relating to the region's prehistory and the period of the Napata, Meroe, Kush kingdoms that were contemporary with ancient Egypt. The Khalifa's House in Omdurman contains a collection of relics from the Mahdist period of the nineteenth century. Khartoum also has museums devoted to natural history and ethnography. The University of Khartoum Library is renowned for its collection of Sudanese and African traditional objects; the Flinders Petrie Library (named after the renowned Egyptologist) and the National Records Office hold a large collection of historic documents.

## LITERARY AND ARTISTIC LIFE

Sudanese literature has been shaped by oral culture and the written word. Ancient chronicles still exist such as those produced during the sixteenth-century Funj Kingdom. The Tabaqa of Sennar, which relate the lives of the Muslim saints of Sennar, dates from the early nineteenth century. Modern Sudanese poetry has been strongly influenced both by English romanticism and classical Arabic literature. On the eve of the First World War, Sudanese poetry played an important role in the search for a Sudanese national identity as illustrated by the literature of Tambal: 'the poetry written by a Sudanese poet, the manifesto of an entire generation, should reflect Sudanese sensibility and the Sudanese landscape'.

From 1932 to 1973, the literary review *Al-Fajr* brought together young poets devoted to promoting the country's literature, including the engineer, diplomat and writer Yusuf al-Tinni, and Al-Tijani Yusuf Bashir, who in the course of his tormented 27-year existence became one of the greatest Sudanese romantic writers. The following generation were supporters of the Third World and pan-Africanism. They launched the review *Les tempêtes révoltées*, which featured Muhyi al-Din Faris and Mubarak Hassan among others. They were closely followed by Abdallah al-Tayeb and Muhammad al-Mahdi al-Magzub, who broke the rhythms of traditional Sudanese folk poetry. Sudanese villages provide the setting for novels such as *A Season of Migration to the North*, which mixes Arabic with the languages of Darfur. Tayeb Salih, Rauf Mussad and Jamal Mahjub, now in exile, head the list of great contemporary writers.

In the realm of the arts, Sudanese music, based on the extremely rich traditional genre known as Maqam, is currently undergoing modernization. It is experiencing a renaissance under the influence of modern Egyptian and Western instruments. Sudanese vocal art, directly influenced by Arab music, is renowned for its extreme melodic sophistication. Today, Sudan's traditional and classical music genres are under threat by the mass media and globalization. At the same time, the oral tradition remains one of the essential sources of Sudanese music, particularly in the southern regions, where it is firmly embedded.

## THE DEVELOPMENT OF MEDIA CULTURE

Media culture, which remains under state ownership, has affected all aspects of Sudanese culture. Radio broadcasting, which began in Sudan in 1938, is largely credited with opening up the entire country to modernity by targeting the traditional communities as in all the Arab-speaking countries of Africa. Its programmes, broadcast throughout the country, greatly contributed to the spread of the Arabic of Omdurman.

Television was introduced in the 1960s, enabling images to reach the smallest villages along with a plethora of melodramatic Egyptian films. Among Arab countries, Sudan has remained greatly dependent on Egypt with regard to the cinema and in other areas of media culture. The press and publishing are developing as the cultural sphere expands, the most widely read newspapers being *Al-Ayam*, *Al-Sahafa* and the English-language monthly, *Sudanow*.

## THE MAGHREB
## LIBYA, TUNISIA, ALGERIA, MOROCCO, MAURITANIA

*Saidou Kane*

## MAGHREB SOCIETIES (1914–1954)

Well aware of Europe's expansionist ambitions, Morocco and the countries of the former Ottoman Empire in North Africa (Algeria, Tunisia, Libya and Egypt) experimented with all forms of European-inspired modernization (e.g. the Tanzimat reforms in Egypt) to prevent the direct colonization of their countries, which were deemed 'backward and therefore suitable for colonization'. Consequently, customs and institutions attempted to integrate the distinctly Western concepts of constitutionalism, exercise of civil liberties, secularization of justice, liberty of thought, secular education, etc. The reformers acknowledged Europe's superiority not only in technical matters but also in numerous other fields, except religion.[1]

The far-reaching liberalization demanded by Europe resulted in the destruction of the Islamic legal system. The community dimension of Islamic law (protection of collective property, guarantee of a just wage, condemnation of usury) was seen as a barrier to the new property and commercial speculation.[2] However, neither reform programmes that reduced the authority of the independent state and enriched the foreigners, nor the settling of the debts contracted by local governments could prevent the progressive occupation of the countries of the Maghreb by the colonial powers claiming to ensure more effective protection for European investments in those countries. The economic and legal means that made vassals of the countries of the Maghreb at the end of the nineteenth and the beginning of the twentieth centuries was the prelude to military violence that persisted until the mid-1930s. For over a century, the project to colonize the Maghreb had been the centrepiece of the strategy for the replacement of the local Ottomans in north and north-east Africa.[3]

## DISMANTLING OF TRADITIONAL SOCIETY

Colonization brought about the reorganization of the Maghreb region and greatly affected the condition of its inhabitants and their relation to the social and cultural environment. The policy of settlement in Algeria, the protectorate in Tunisia and Morocco, and the more or less direct colonization of Mauritania and Libya were accompanied by development and industrialization that paved the way for dispossession and the confiscation of land, as well as the loss of key aspects of society and culture in the Maghreb.

The region's population quadrupled in less than a century. From 1936 to 1947, the urban population of Morocco grew by one million. In Tunisia, urbanization increased from 23 to 32 per cent between 1921 and 1956; in Algeria, the urban population doubled from 1936 to 1954.[4]

### Changing lifestyles and culture

The new urban structures and the sociocultural, educational and transportation infrastructure of colonial society rapidly altered the lives of town-dwellers. Cities modelled on principles of European town planning were built alongside existing traditional towns, which became the 'medinas', or historic centres, of these hybrid urban structures. The modern city of Fez, built alongside the old city by the French Resident-General Lyautey, best exemplified this modernizing trend.

The different layers of society that were drawn to the new urban lifestyle contributed to the severing of traditional community relations. For example, women enjoyed greater freedom in the towns, which facilitated looser marital ties than did the lineal, clan or tribal system of the less urbanized areas. In the towns, the elite, trained at the modern education institutions, looked forward to the Westernization of their society and to a new interpretation of Islam better suited to modern conditions. The traditional elite, or *ulama*, crystallized aspirations for a form of modernization free from foreign domination, along the lines of the modernist Arab-Islamic reform culture proposed by Jamal al-Din al-Afghani (1839–1897) and Muhammad Abduh (1849–1905).

## Challenging the colonial order

The frustration resulting from the cultural and economic loss inherent in the colonial process served to foment the ideas of pan-Islamic nationalism between the 1920s and the 1950s. Some national movements and parties, distant echoes of the 'Young Tunisian' and 'Young Algerian' movements of the beginning of the century, dealt colonization some heavy blows. Among the early anti-colonial movements: the Entente for National Liberation, the Association of Ulama of Ben Badis, the Étoile Nord-Africaine led by Messali al-Hajj, and the Évolués of Ben Jelloun and Ferhat Abbas, in Algeria; the Neo Destour (New Constitution) Party and the Union Générale des Travailleurs Tunisiens, in Tunisia; and the Istiqlal party, in Morocco.

## The new Maghreb: scientific and technological development and cultural renaissance

The northern Maghreb is one of the rare regions of the globe where French colonialism had the resolve to put in place the structures essential for the development of a modern economy. Nevertheless, French policy failed to satisfy the requirements for the internal development of modern states, and it could be argued that it even produced certain handicaps in the form of obsolete equipment left behind by the colonizers.

The cultural renaissance was enriched by the osmosis between the traditional Maghrebian cultures and the European heritage. This dual tradition was noteworthy in the fields of the arts, literature and architecture through which the Maghreb sought to restore the historical links that had been severed for more than half a century. The Maghreb refocused its attention on the traditional Earthen habitats known as *ksour* (Matmata, Tatouine, Takrouna, Toggourt, Ouadane, Chinguetti, Ksar Hadada, etc.) and the architecture of the northern cities (Tlemcen, Fez, Algiers, Tunis, Constantine).

The Maghreb also revamped and redeveloped other components of its cultural heritage, including the weaving of carpets, and other traditional woven crafts such as *mergoums* and *bakhnougs*. So successful was Tunisia in rejuvenating such crafts traditions that it assisted Mauritania in reviving its tapestry production by providing training grants. Algeria rediscovered Berber music, particularly from Kabylia, through the rai movement.

Theatre, which appeared in the Maghreb during the period between the two world wars, developed rapidly. The author of the acclaimed novel *Barrage* (1940), Tunisian writer and former education minister Mahmud Messadi, paved the way for a literature of the Maghreb free from the strictures of foreign influence.

Born in Egypt in 1917, the Arab cinema continued to be dominated by melodramas, musicals and comedies. The arrival of the talkies stimulated film production, and anti-colonial themes first appearance around 1952. The Maghreb made its mark in the motion picture industry in 1958 with the film *Goha*, shot in Tunisia by Jacques Baratier from a screenplay by Georges Schéhadé. It was not until independence, however, that the Maghreb turned to anti-colonial themes. Clearly the Algerian War became a predominant theme. The Algerian Lakhdar Hamina Mohamed gave a boost to the Algerian motion picture

industry with his film *Le vent des Aurès* (1965–66). In *Les mille et une mains* (1972), Moroccan filmmaker Souhayl Ben Barka revealed the sufferings of the workers toiling in the dyers' souk of Marrakech and offered a new perspective on the increasing social problems. In 1975, Lakhdar Hamina returned to the screen with *La chronique des années de braise*, which depicts the tribulations of the Algerian people. In 1972, anti-immigration xenophobia in France was explored by Mauritanians Med Hondo (*Les bicots, nègres, vos voisins*), and Sidney Sokhna (*Nationalité: émigré*).

Twentieth-century Maghrebian literature acted as a catalyst for analysing the evolution of societies resulting from the fusion of components from the West, the Arabic-speaking world and sub-Saharan Africa. Commenting on the *nahda* or Arab renaissance, the Egyptian intellectual Anouar Abdel Malek draws attention to the very rapid development of a distinctly Arab culture reflected in conceptual vocabulary, the style of expression and the rhythm of the language. In this regard, after the First World War, the great writers of the older generation (e.g. the Tunisian poet Shabbi) continued to exert an influence on the literature of the Maghreb. Moreover, the 1960s generation of writers – Abdellatif Laabi, Kheireddine and Tahar Ben Jelloun (Moroccan), Mahmoud Messadi (Tunisian) and Jean Amrouche and Kateb Yacine (Algerian) – became the spokesmen for those without a voice. The autobiographical novel of Mohamed Choukri, *Le pain nu*, which was banned for 17 years by the Islamic establishment because of its radical denunciation of certain relationships between parents and their children, delighted anti-conformists. Mohammed Dib, Malek Haddad, Kateb Yacine, Assia Djebar, Rachid Mimouni and Rachid Boudjedra in the north, and Tène Youssouf Guèye, Jémal Ould Hassan and Ahmedou Ould Abdel Kader in the south of the Maghreb, echoed the hopes and contradictions of a society in search of its roots and its place in the Arab-Muslim, African and modern world.

Towards the end of the twentieth century, the media culture began to monopolize the spoken word in the Maghreb. From ascetics to troubadours, from politicians to men and women of culture, the leading players in society expressed themselves essentially through the press, radio and television, but means of communication continued to be tightly controlled by the state. The transistor radio, which appeared in the Maghreb in the 1960s, increasingly gave way to the new medium of television, which was implanted in nearly all towns, villages and encampments. These media are expected to enable the Maghreb to emerge from centuries of backwardness.[5]

## CONCLUSIONS AND ORIENTATIONS

*Anouar Abdel-Malek*

To be sure, all areas of the non-hegemonic Western world, from the sixteenth century until the late twentieth century, have been made dependent on, and even occupied by, Western powers thereby leading to uneven development and marginalization. Yet the Middle East continues to experience protracted waves of aggression coupled with concerted isolation, from the early Crusades until the present day via centuries of colonialism and imperialism. The wider region of the Middle East witnessed the gradual weakening of ancient civilizations, cultures and empires – a process which has left a deep imprint on the entire region, albeit with different levels of intensity. It follows that a serious study of the wider Middle East today has to take into account the overall cultural and societal crises caused by protracted aggression and dependence. Hence, the specific nature of the problem, which each and every society of the Middle East must face. At the heart of the matter, lies a two-part question: What is the cause of the decadence, and how can a revival or renaissance be achieved?

A first wave of questioning began, quite naturally, from the comparison between the West, mainly Europe, and the Middle East. European modernity was closely linked to a perception of the human environment by means of rationality, the satisfaction of human and societal needs, and the convergence of scientific, industrial and bourgeois democratic revolutions. Hence the first part of the answer: the decadence of the Middle East can be seen as the direct consequence of the incapacity of their societies to understand, and benefit from, the processes and achievements of European modernization. Decadence could only be overcome through the imitation of the advanced world. This modernist orientation was predominant during the first half of the nineteenth century.

After the 1840s, however, Europe began its onslaught on the Middle East region, particularly on the southern and eastern shores of the Mediterranean. Finance capital buttressed by direct military interventions revealed the limits of the liberal-modernist orientation. If a partnership could not be achieved by imitating the West, it was necessary to seek a more convincing answer to the two-part question raised above. Gradually, influential thinkers and activists committed to preserving the major societies of the Middle East felt that the immersion in their cultural roots would provide the required answers. Since the seventh century AD, these roots were mainly Islamic, yet, Islamic societies were now perceived as decadent.

Centuries of decadence resulted from allowing centuries of dogmatism, deformations and dead weight. Hence the path to a renaissance: the return to original truths and to the very foundations of Islam would clear the way for a genuine interaction with modern times, based on a careful and unrelenting use of common sense. Such was the path defined by the Islamic fundamentalists. However, their position was firmly rooted in the belief that orthodoxy was the only ideology appropriate for the Ummah, or the Muslim community as a whole.

By the early twentieth century, national independence movements struggling against foreign domination were consolidated as Western imperialism sought to divide West Asia and the Arab nations by proceeding beyond penetration and occupation. The First World War led to the Balfour policy in Palestine, the Sykes-Picot agreement to divide the Middle East between Great Britain and France, the amputation of Turkey, as well as the US control of the oil reserves in the Arabian Peninsula and the Gulf region, as well as in Iran. Thus the Middle East was forced to bear the brunt of direct imperialist occupation and rule. Hence the differentiation of each of the two orientations into a conservative and radical wing, thus opening the path towards a united national front dedicated to liberation, democracy and social justice. Eastern societies in the Middle East, having thus become the centre of the rising tide of tensions, were bound to enact measures enabling them to take action. Quite naturally, these measures were implemented at the national level.

In the Arab world, the notion of the two-tiered nation gradually emerged, particularly at the time of the rise of the Arab national unity movement in the mid-1950s. The first level was defined as the actual status of concrete national societies, the recognized nations of the international community. While the second level brought together all national units in the wider circle of their common cultural context. On the other hand, the wider cultural historical circles of Iran and Turkey were perceived more as a socio-cultural area than as a regrouping of different national units.

Such were, and still are, the complex processes at work at the very heart of Middle Eastern societies. Yet, there seem to be additional factors that can explain the exceptionally

acute nature of processes now unfolding at the socio-cultural level. This can be understood in terms of the dialectics between the surge towards modernity and resurgence in the most complex geopolitical areas of our times, with great tension between specificities and universality.

How could historical positivism be secured and sustained in light of the relentless pressure of external negative factors? Quite naturally the level of the superstructure – ideas, beliefs, values – appeared more capable of providing a positive outlet. Education – from the eradication of illiteracy to the creation of centres of academic learning and scientific research – was, and remains, the most visible weapon against centuries of isolation and regression. The questions of national defence and security had to be faced simultaneously with the vital requirements of socio-economic development and cultural modernization.

Thus, the march towards a national society and cultural modernization proceeded despite great constraints. From the onset, the development of infrastructures at the national level required clarifying certain contradictions throughout the Middle East: the dialectics of specificity and universality, centring on the quest for a clear vision of national identity in all societies of the region, albeit with different degrees of urgency.

The quest for a clear vision of national identity emerged as the direct consequence of the region's historical processes. The decline of the Ottoman caliphate, with its centre in Turkey, led to the emergence of a series of new states in the Arab Near East and North Africa. These national states had been ruled as provinces of the Ottoman Empire until the new borders were drawn up by the victorious Allied powers after 1918. Thus Turkey emerged from its war of independence as a sovereign national state ruling a much-reduced territory. New states were created, either as the restoration of previous historical formations, or more often as the creation, literally, of new political entities mainly from the Arab Near Eastern hinterland to the Persian Gulf. Hence the quest for the greater circle of national cultural identities: the Arab nation, in the Near Eastern sector of the Arab world; as well as the orientation towards the wider historical geo-cultural areas of Turkey and Iran in West and Central Asia; the greater Maghreb North Africa; and the Nile Valley union.

Having taken stock of the present situation in the Middle East helps us to examine the questions about the future with a degree of realism and clear-sightedness.

The future raises the question of feasibility in the new global environment. To be sure, the incorporation of the Middle East in the globalization processes, albeit with severe difficulties, can strengthen this vision. Yet, questions abound as we explore the concrete processes. How would the optimal model of economic modernization and development be defined? Obviously, the liberal, or neo-liberal, model can fail to address the very different processes and factors at work in the societies under study. However, since the traditional centralized economy does not provide the required flexibility, original models of development, bringing together the private and public economic sectors in various configurations, are required. Those working in the economic field would like to give priority to the major ongoing modes of accelerated development and societal transformation, now being implemented with unprecedented success mainly in East Asia, and in certain parts of Latin America. Similar developments will occur in the cultural

sector. To address these questions, these countries must ensure the training of new types of cadres, thinkers and actors, who must be future orientated while at the same time maintaining a genuine respect for living traditions in a modern context.

The dialectics of universality and specificities lies at the very centre of any meaningful analysis of concrete societies. Differences between the centre and peripheries often brings to the fore the notion of *exceptionalism* – as if the East, including the Middle East, could not be understood owing to its 'exoticism'. Such are the difficulties in studying Western societies. A first attempt to bridge the gap between the Western and Eastern cultures leads us to study their differences. From the onset, this approach of studying differences, while leading to a better definition of quantitative differences, fails to examine the complex factors that explain the wide panoply of differences within the all-encompassing global unity of humankind. Briefly stated, the study of difference attempts to bring together societies formed by vastly different, geo-historical conditions. However, the major difference between advanced societies and marginalized developing societies resides in the fact that the advanced developed societies have access to 'historical surplus value', while developing societies had, and still have, no access to such privileged conditions.

Hence the need to seek a more meaningful mode of understanding differences with a view to identifying points of convergence. This explains the urgent search to define a new model on the part of the innovative thinkers and activists of developing nations, particularly in the Middle East and Latin America. This search led to the elaboration of the concept of specificity in the 1960s and 1970s.

Characteristics shared by all societal formations are: the production of means of subsistence (economy), the continuity of human life (reproduction), social power (the state), the relation to time (transcendence: philosophies, religions). Societies structured around these four common dimensions vary according to their geographical and geo-political context through history. Obviously a nomadic society existing in a peripheral geo-political location over a relatively short period of time is profoundly different from a stable agricultural society whose major urban and social power centres are located in a sensitive geo-political area. Thus, the distinctness of any given society could be defined on the basis of its geo-historical formation rather than its postulated spiritual disposition. Thus it is necessary to recognize the specificity of the peripheral developing societies, as well as the specificity of each and every advanced developed society. The bridge was thus built to make sense of the dialectical differences and tensions within our common world, enabling all concerned to seek areas of convergence while avoiding destructive confrontations.

The recognition of specificity prompted a deeper examination of the values and goals of advanced patterns of development. If peripheral societies cannot aspire to joining the ranks of advanced societies in the near future – as is the case in most parts of the Middle East – perhaps the values and aims of advanced societies, mainly in the West, differ from those of Middle Eastern countries. In other words, could there be different modes of development leading to different goals in spite of the reputedly universal nature of fundamental values? This questioning arose in societies with a long history of progress and crisis. They were related

to but not directly influenced by societies that came to prominence after the age of maritime discovery, the Renaissance and the scientific and industrial revolutions. Most of the Middle Eastern societies are keenly aware of their past. Hence their tendency to reflect on the role of civilization and of their being part of major cultures that laid the foundations of the modern Western world. Thus, the search for alternative aims, values and projects emerged as the very foundation of possible futures for the West-Asian and Arab societies and as an alternative to a mere imitation of the dominant socio-cultural patterns. And this search quite naturally gave prominence to ideas and values beyond more restricted material and economic considerations. Thus the search for alternatives centred on the level of civilization.

This major orientation has taken place at a time when a sense of crisis seems to pervade the contemporary Western world. Major fratricidal and world wars, serious incidents of racialism and intolerance, coupled with the unpredictability of economic development, increasing self-questioning in the West, division rather than agreement appeared to constitute the very texture of the twentieth century, at a time marked by the rise of a renewed self-assertiveness on the part of Eastern societies and national liberation leading towards renaissance.

The 'civilizational' orientation of Middle Eastern societies is gaining momentum at this historical period when social thinking in major centres of the world stresses the role of civilization in contemporary ideas and projects, in light of nuclear and ecological threats, with the objective of peace and harmony in the world. In this context, the ongoing development processes of West Asian and Arab societies demonstrates a determination to aspire to a type of modernity that combines the notion of cultural heritage with the economic, scientific and technological requirements for contemporary developments. In this quest, communitarianism and solidarity occupy a central role in opposition to confrontation, individualism and hegemony. Human values, a normative approach, religion and philosophy take precedence over material achievements.

This 'civilizational' orientation can enrich the processes of bringing different civilizations and cultures together. Yet, the forging of the new world is now proceeding along dangerous confrontational paths. Challenge can give way to promise, should optimal time be allowed for West Asian and Arab societies to advance peacefully towards achieving a more advanced degree of modernity with respect to the specific nature of their cultures.

As ever, time is of the essence – 'time, the refreshing river' (Joseph Needham).

### INTRODUCTION

This chapter covers the main trends in the scientific and cultural development of sub-Saharan Africa in the twentieth century. At the beginning of the century, Africa was dominated by the colonial powers – Great Britain, France, Portugal, Germany, Belgium, Italy and Spain. The area under British rule included: Nigeria, the Gold Coast (Ghana), Sierra Leone and the Gambia in West Africa; Uganda and Kenya in East Africa; Nyasaland (Malawi), Northern and Southern Rhodesia in Central Africa; the four colonies of the Cape, Natal, Transvaal and Orange Free State, as well as Basutoland, Bechuanaland (Botswana) and Swaziland in Southern Africa. France controlled a large area known as French West Africa, including Senegal, Mauritania, Mali, Guinea, Cote d'Ivoire, Dahomey, Upper Volta, and Niger; and the smaller French Equatorial Africa (Chad, Gabon, Middle Congo and Central Africa). The Germans held German East Africa, Kamerun, Togo and South-West Africa. Leopold, King of Belgium, and his associates managed the Congo Independent State as a private venture until scandals about the ruthless methods of exploitation forced the Belgian state to take control in 1908 when it became the Belgian Congo. The Portuguese retained Angola, Mozambique, Cape Verde, São Tomé and Principe and part of the Guinea Coast in West Africa. The Italians occupied Eritrea and shared the Horn with the British and the French. Spain controlled the island of Fernando Po and the stretch of the coast around the mouth of Rio Muni. Even Ethiopia and Liberia, which managed to remain independent, were under the shadow of the colonial powers that dominated their neighbours.

At the end of First World War, the victorious Allied powers decided that the Germans had proved morally unworthy to rule Africans as a result of the brutalities in the suppression of the Maji Maji revolt in East Africa and of the Herero in South-West Africa. The main accusations were flogging, forced labour, bloody suppression of rebellion, 'barbaric destruction of tribes' and the arming of

Africans. These claims related mostly to events before 1907, when a supervisory Colonial Office was established to carry out reforms.[1] Although the Allies committed acts as atrocious as those carried out by the Germans, the victors occupied the German colonies, and proceeded to distribute them: Togo and Kamerun went to the British and the French; German East Africa to the British, who took Tanganyika, and the Belgians, who henceforth controlled Ruanda-Urundi; South-West Africa was governed by the Union of South Africa. The year 1918 thus marked the end of the process of conquest and partition and ushered in the concepts of 'trusteeship' and 'mandates' to be supervised by the League of Nations, a responsibility that was passed on to the United Nations after the Second World War. Despite this, the post-Depression rise of fascism in Europe tightened the grip of racism in colonial Africa, producing a new wave of immigration of poor whites into Angola, Mozambique and Eritrea, the Italian invasion and conquest of Ethiopia, and the doctrine of apartheid in South Africa. But it also led to the rise of militant nationalism in Africa and hastened the demand for independence.[2] Colonial domination persisted until the 1960s, that is, for two-thirds of the century, before political independence began to be conceded to the states created by the colonial powers. Even afterwards, the colonial legacy remained a powerful factor in the development of Africa. It will be necessary, therefore, to discuss the scientific and cultural development of Africa in three parts: (i) the policies and strategies of the colonial powers; (ii) the aspirations of the African peoples as enunciated in the struggle for decolonization and independence; and (iii) the policies and programmes of the post-independence African states.

Development, defined as changes in the social, economic and political life that result in improvement in the overall well-being of society, is widely considered to be the goal of all governance and social life. Scientific and cultural developments are interrelated strategies in the pursuit of overall development. Cultural policy involves defining the

strategies necessary to promote the human resources and way of life to enhance the development of the necessary skills and technologies. It is thus essential that science and technology be seen as integral parts of the culture so that, in promoting culture, science and technology can be enhanced, and vice versa. Every society and every culture has some level of science and technology that sustains it, particularly in the fields of agriculture and food production – including animal husbandry, hunting, fishing – and health care. There are science and technology also in various crafts and economic activities such as glass-working, weaving, pottery, gold and silver smithing, metalworking, etc. Science and technology are promoted through education, apprenticeship, religion, trade and other forms of social interaction and exchange. It is true that significant advances in science and technology are sometimes made in periods of crisis and national emergency, but they flourish best in an atmosphere of freedom where human dignity and cultural identity are encouraged, and enterprise, initiative and innovation are promoted. Since colonial domination, by definition, denies such an atmosphere of freedom and enterprise, it implies the very negation of development. Yet, it was under colonial domination that Africans had to seek development during most of the twentieth century.

In the pre-colonial period, most African societies welcomed trade with Europeans, Arabs, and Indians (particularly in Eastern Africa). Through its commercial relations with Egypt, Axum adopted the Coptic Orthodox Christian religion in the fourth century, using it as a means to establish some cultural unity over the Ethiopian plateau. The Church, under the leadership of the emperor, promoted education especially among the clergy and the ruling classes. This included not only literacy and advances in agriculture, but also some remarkable achievements in art and architecture, including the stone churches that are now inscribed on UNESCO's World Heritage List. The Arabs conquered North Africa, including Egypt and the Nile Valley, and gradually penetrated into the Western Sudan through trading (primarily slaves but also gold and ivory). Islamic culture promoted art, architecture and scholarship. It rediscovered the science of the ancient world, that of the Greeks and Romans that was much influenced by Egypt, and which the Islamic universities developed and propagated. The flowering of Islamic culture in the Sudan belt in the nineteenth century through a succession of jihad movements, beginning with Sokoto, spreading to Massina and the Tukulor, to the Mahdist state in Khartoum, set the stage for cultural development in the twentieth century. Islamic movements continually threatened the Christian state of Ethiopia. This persistent threat made cultural, scientific and technological development a necessary condition for the survival of the empire.

Various peoples in Western and Central Africa welcomed the Europeans who came to trade at the end of the fifteenth century. Soon, the Europeans limited their commercial activities to the slave trade in order to feed the insatiable demand for labour in the Americas. Trade became exploitation through unequal exchange. In the course of the nineteenth century, the Europeans proclaimed their determination to abolish the slave trade and to replace it by trade in agricultural produce, notably palm produce and groundnuts, as well as cotton, ivory, timber and sisal hemp. Their objective was to facilitate the activities of Christian missionaries, who sought to evangelize, study the languages,

make the Bible available in those languages, and promote schools and training colleges. Not without some resistance, the people welcomed the new trading policies. They encouraged the work of the missionaries in the belief that through literacy and Western education, their children would acquire some of the technology that enabled Europeans to manufacture such large ships and powerful guns, watches, and other interesting objects. The influence of missionaries was spreading, but the most notable centres of missionary work were to be found in different parts of the coast of West Africa, Southern Africa, and Madagascar. It has been said that the proportion of children in Western-type schools in Freetown and Antananarivo in the third quarter of the nineteenth century was higher than in most parts of rural Europe. Thus, the foundation was already laid for Africa's thirst for Western education and technology in the search for development, even before the European conquest, partition and imposition of colonial rule. In many places, while the chiefs mobilized armies to resist conquest, many missionary-trained Western-educated Africans welcomed European rule in the hope that it would facilitate access to Western education and technology. This hope was often frustrated.

## THE COLONIAL FACTOR

Under colonialism, the key to cultural and scientific development was obviously the spread of Western education, which was seen as the most essential aspect of the 'native policy'. In most parts of Africa, the missionaries propagated Western education as a means to evangelization. Western education was thus closely linked with the spread of Christianity, with obvious implications for cultural identity. For Muslim communities in particular, it presented the problem of how to acquire Western education without losing their own cultural identity, including traditional religious education. The ambivalent attitudes of the colonial rulers to the spread of education illustrated the gap between the theory and the practice of colonial rule.

### The Ethiopians and the Italians

The rejuvenation and expansion of Ethiopia under Menelik II at the end of the nineteenth century provides a necessary background to the history of scientific and cultural development in Ethiopia and the Horn country in the twentieth century. It is typical of attempts at modernization from within by several states in Africa, such as the Sokoto, Massina and the Tukulor states of the jihad movements in West Africa, the Mahdist state in the Sudan, the Nguni states of Southern and Central Africa, and the Merina state in Madagascar. Some of these relied on a revival of the Islamic faith and culture, others on the transformation of traditional cultural leaders into military and executive rulers. All made overtures to European traders or missionaries for the acquisition of improved guns and new technologies, while resisting cultural alienation and territorial encroachment. Europeans took advantage of any openings to transform trading relationships into conquest and colonial rule. The struggle for development in Africa thus involved a constant struggle to borrow modern techniques from Europeans without losing cultural identity,

and while defending or trying to regain independent political and economic existence. The situation was often complicated by the ethnic and cultural diversity of the peoples grouped arbitrarily by the Europeans into the colonial states, with their internal struggles and diverse responses to colonial rule.

Scientific and cultural development was essential for the survival of the Ethiopian empire from internal divisions and the pressures of external powers, which came not only from Europe, but also from Egypt and the Sudan. In his conquests of southern Ethiopia, Menelik saw himself as reclaiming lands that were once part of the empire before the jihad of Ahmed Gran in the sixteenth century expanded the frontiers of Islam and precipitated the immigration of both Muslim and non-Muslim Oromo. The conquests were consolidated with fortified outposts manned by carefully selected governors who supervised the work of priests building churches and schools, spreading Amharic language and culture, putting pressure on the traditional rulers to embrace the Coptic Orthodox Church, and promoting urbanization. Having failed to win Massawa from the Egyptians, Menelik had to rely on diplomacy to maintain access to the outside world. He saw the British and the French as the major threats to his imperial authority. He therefore leaned more towards the Italians for external recognition and supply of arms and ammunition. For this reason, he yielded to Italian claims on the coast and in Eritrea. When the Italians tried to exploit this to change Ethiopia from an ally into a protectorate, he resisted and defeated the Italians at the Battle of Adwa. In spite of several international treaties, Menelik was not allowed to participate in the Berlin Conference of 1884–85. His territories, like the rest of Africa, were treated as 'no man's land' or *terra nullius* in international law. But Ethiopia survived as the only traditional African polity that escaped the imposition of colonial rule. For the rest of Africa, Ethiopia became the symbol, and Ethiopianism the slogan, of Christianity with an African identity, a non-Western religion, and a vehicle of African nationality in the modern world.[3]

The process of Italian pacification in Eritrea and Somaliland was by no means over by 1918. The Somali shared a common language and culture, but were divided into several clans and polities. Sporadic revolts continued until the end of the 1920s. In their resistance against the various colonial powers and Ethiopia, especially with the pan-Somali appeal of al-Sayyid Muhammed's jihad of 1897–1920, the Somali began to develop new consciousness of a common Somali nationality. This was further aided by the Osmanya alphabet, invented in 1920 by Uthman Yusuf Kenadid, which began to spread in spite of the hostility of the Italians and conservative clerics who preferred the Arabic script. Nevertheless, the Italians were determined to exploit the resources of the territories, at minimal costs to themselves. They established a framework of administration and made grants of sizable agricultural lands to concessionaries, which selected chiefs to collect taxes and recruit labour to work on the plantations, either by coercion or the manipulation of taxation. By 1930, as Italian control became consolidated, and with the rise of Fascism, colonial exploitation became a national programme. Concessionaries were phased out, elaborate plans were made for large-scale immigration of Italian settlers, and substantial investments were made on

infrastructure in roads, irrigation, and research in field stations and metropolitan institutes. Colonial rule became more authoritarian, and systematic racism was decreed, including the prohibition of interracial marriages, and the dissolution of those that predated the decree – a foretaste of the elaborate South African system of apartheid.

Under Fascism, the desire to invade and conquer Ethiopia to avenge the defeat at the Battle of Adwa in 1896 became a prime objective of the Italian state. After making elaborate plans, Italian forces suddenly invaded Ethiopia from the north early in October 1935. They moved very quickly and occupied Adwa by 6 October. The League of Nations condemned the action and imposed limited sanctions on Italy. They did not want to provoke Italy and did not care enough about Ethiopian independence to impose such sanctions – for example, a blockade of oil supply – that could deter it. Thus betrayed, Ethiopia fought alone. Their resistance gathered strength and remained unshaken until Italy resorted to the use of poison gas, which enabled them to occupy Addis Ababa by 6 May 1936. The policy already established in Eritrea, of expropriation of land for the benefit of large-scale immigration of Italian settlers, was extended to Ethiopia along with apartheid.

Italy was determined to systematically weaken, if not eliminate, the rising Ethiopian educated elite, particularly those trained abroad in science and technology. The Italians were determined to develop Ethiopia with the skills of Italians and the labour of impoverished Ethiopians, for the benefit of Italians. They invested capital, built a network of roads and field research stations. The Fascist assault on the most ancient and venerated polity in Africa south of Egypt galvanized nationalist opinion, not only in Ethiopia and the Horn country, but also throughout Africa. It stimulated the pan-African movement in the Diaspora, and brought the morality of the whole colonial enterprise into question. The British army occupied Ethiopia in 1941 and restored Emperor Haile Selassie to his throne. Colonialism was shaken, but it was far from being defeated in Africa, even in Ethiopia.

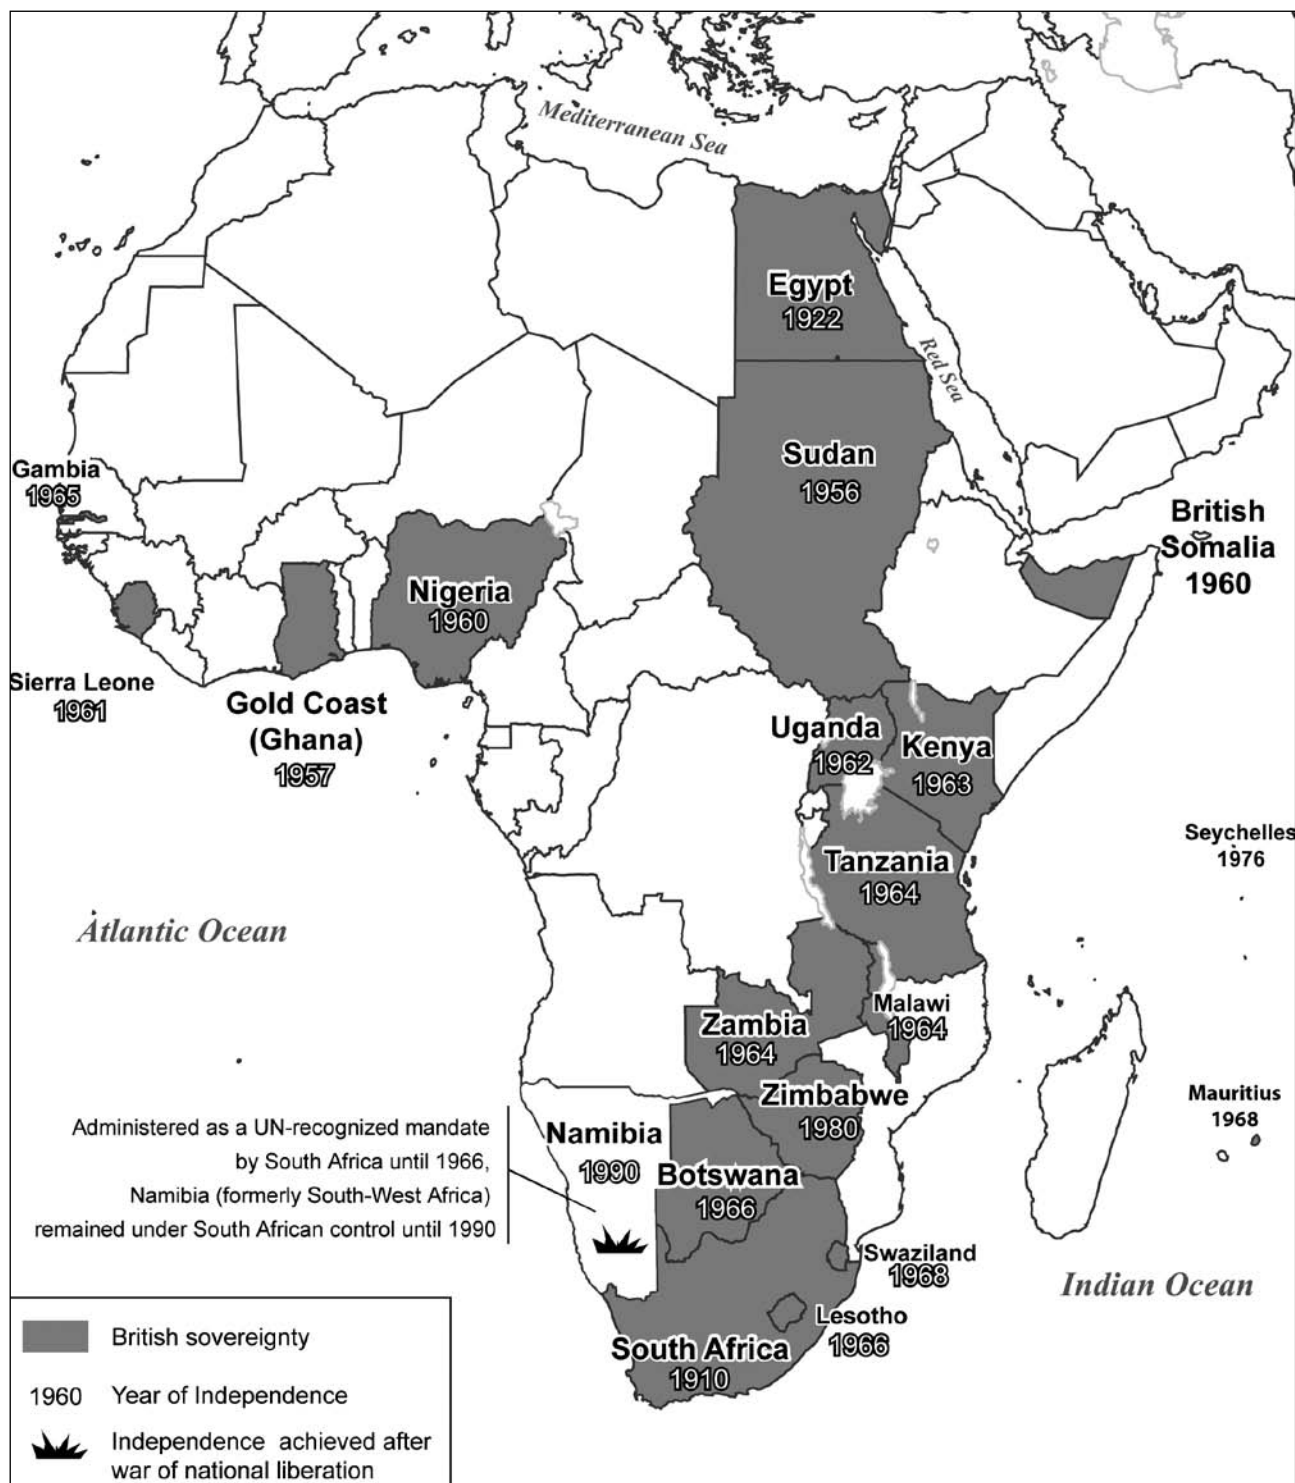
**Great Britain**

British Africa started from crown colonies like Freetown, Barthust and Lagos, with institutions based on metropolitan models. A high literacy rate resulted from the close collaboration with missionaries, especially for the care of freed slaves. Beyond these, the vast areas acquired during the 'scramble' for Africa were protectorates. Large parts of these were placed under the control of concessionaries or chartered companies. When these were phased out, they were replaced with the system called Indirect Rule, in which colonial officers, wherever possible, delegated some local responsibilities to reconstituted 'native authorities'. The aim was to keep down expense and govern with the minimum of staff.

Generally, the British saw the need for a limited number of people with some Western education who could be subalterns of the colonial work force as messengers, interpreters, clerks, medical and veterinary assistants, etc. The British were willing to leave the basic training of such people to various Christian missionary bodies, whose efforts were supplemented, for example in Muslim areas suspicious of Christian education, by a few government schools devoted to children and the protégés of traditional rulers. From the 1880s onwards, the government gradually built up a system

of monitoring the performance of such schools through inspection. The granting or withholding of approval and grants-in-aid were used to enforce compliance with government guidelines and regulations.

Eventually, in 1923, an Advisory Committee was set up in the Colonial Office to coordinate the formulation of policy and supervise its implementation throughout Anglophone Africa. The need for such a committee was confirmed in the 1922 report of the US-based Phelps-Stokes Commission, which visited West, Central and South Africa to propagate the Tuskegee Institute's philosophy of 'appropriate policies for the education of blacks'. The Committee endorsed the policies recommended by the Commission and sponsored a second visit and Report of the Commission on South, Central and East Africa. The members of the Advisory Committee, who were influential and powerful and possessed extensive expertise, exerted decisive influence on policy, which

*Map 16* **British colonies in Africa**


reflected the ambivalent attitudes of the colonial office. Some members wished to stimulate the demand for Western education as an agent of social change that would in turn promote development. Others preferred to use educational policies to preserve traditional life and values so as to slow down the pace (and control the direction) of change. The first major statement of the Committee reflected this ambiguity:

> Education should be adapted to the mentality, aptitudes, occupations and traditions of the various peoples, conserving as far as possible all sound and healthy elements in the fabric of their social life; adapting them where necessary to changed circumstances and progressive ideas as an agent of natural growth and evolution[4].

The more progressive members wanted education to adapt traditional values to 'changed circumstances and progressive ideas', but they had to compromise and accept 'natural growth and evolution' rather than change as such as the objective of education. The conservatives had the upper hand and colonial policies emanating from the Advisory Committee remained very restrictive until after the Second World War. Such policies were less effective in West and South Africa than in Central and East Africa. In West and South Africa, missionary bodies had encouraged the establishment of secondary schools from 1840 to 1880. A momentum was created among the former students of such schools and later restrictive colonial policies could not entirely stifle this forward movement. On the other hand, European settlers in Central, East, and eventually in South Africa, and the mandated territory of South-West Africa, exercised such influence on the local colonial administrations as to turn the restrictive policies of the Advisory Committee virtually into obstructive walls. The usual pattern in West Africa was for the missionaries to establish a trade school and for community pressure to convert the trade school into a grammar school emphasizing the classics and religious education. Usually, there was no science taught beyond hygiene and practical agriculture. In Nigeria, with 30 state-assisted grammar schools, it was only in 1929 that the government established the first two government colleges to include science in the curriculum. Training of carpenters, masons, mechanics, tailors, drivers, etc., was usually by apprenticeships in small private establishments. The grammar schools thus concentrated on purely literary pursuits, despite the repeated advocacy of the importance of technical and technological education. In Central and East Africa, secondary education was either non-existent or remained at the level of trade schools. Makerere, established in 1921, remained a trade school offering a wide variety of courses – carpentry, mechanics, para-medical, veterinary, surveying, agriculture, clerical, even teacher training – until 1933 when it became a full secondary school. In Zambia (Northern Rhodesia), the first junior secondary school was established in 1939. Kenneth Kaunda was forced to observe in 1966 that, as far as educational policy in Zambia was concerned, Britain preferred 'financial exploitation to human development'[5].

The impact of colonial educational policies on cultural and scientific education in Anglophone Africa was a complex issue. The missionaries had made significant progress in promoting literacy in several African languages. Several of these languages were used in evangelization and in the schools. This helped to stimulate cultural awareness at the elementary school stage. But the overall impact of colonialism was to focus attention on the culture of the colonial power. The literary grammar school, promoting European culture and alienating the fledgling educated elite from their traditional culture, dominated the perception of parents and even the ambitions of elementary school children. In such circumstances, there was more of cultural imitation than cultural development. In spite of occasional bouts of cultural revival denouncing wholesale imitation of European culture, European names, dress, food, literature, art and sports continued to be preferred to African ones as being more appropriate for educated and civilized persons. This imitation of European culture was featured at Empire Day celebrations, school concerts and other festive occasions. Only classical European music failed to win many African converts, perhaps because the missionaries, most of whom were not high-browed, promoted hymnology rather than classical music as such.

## France

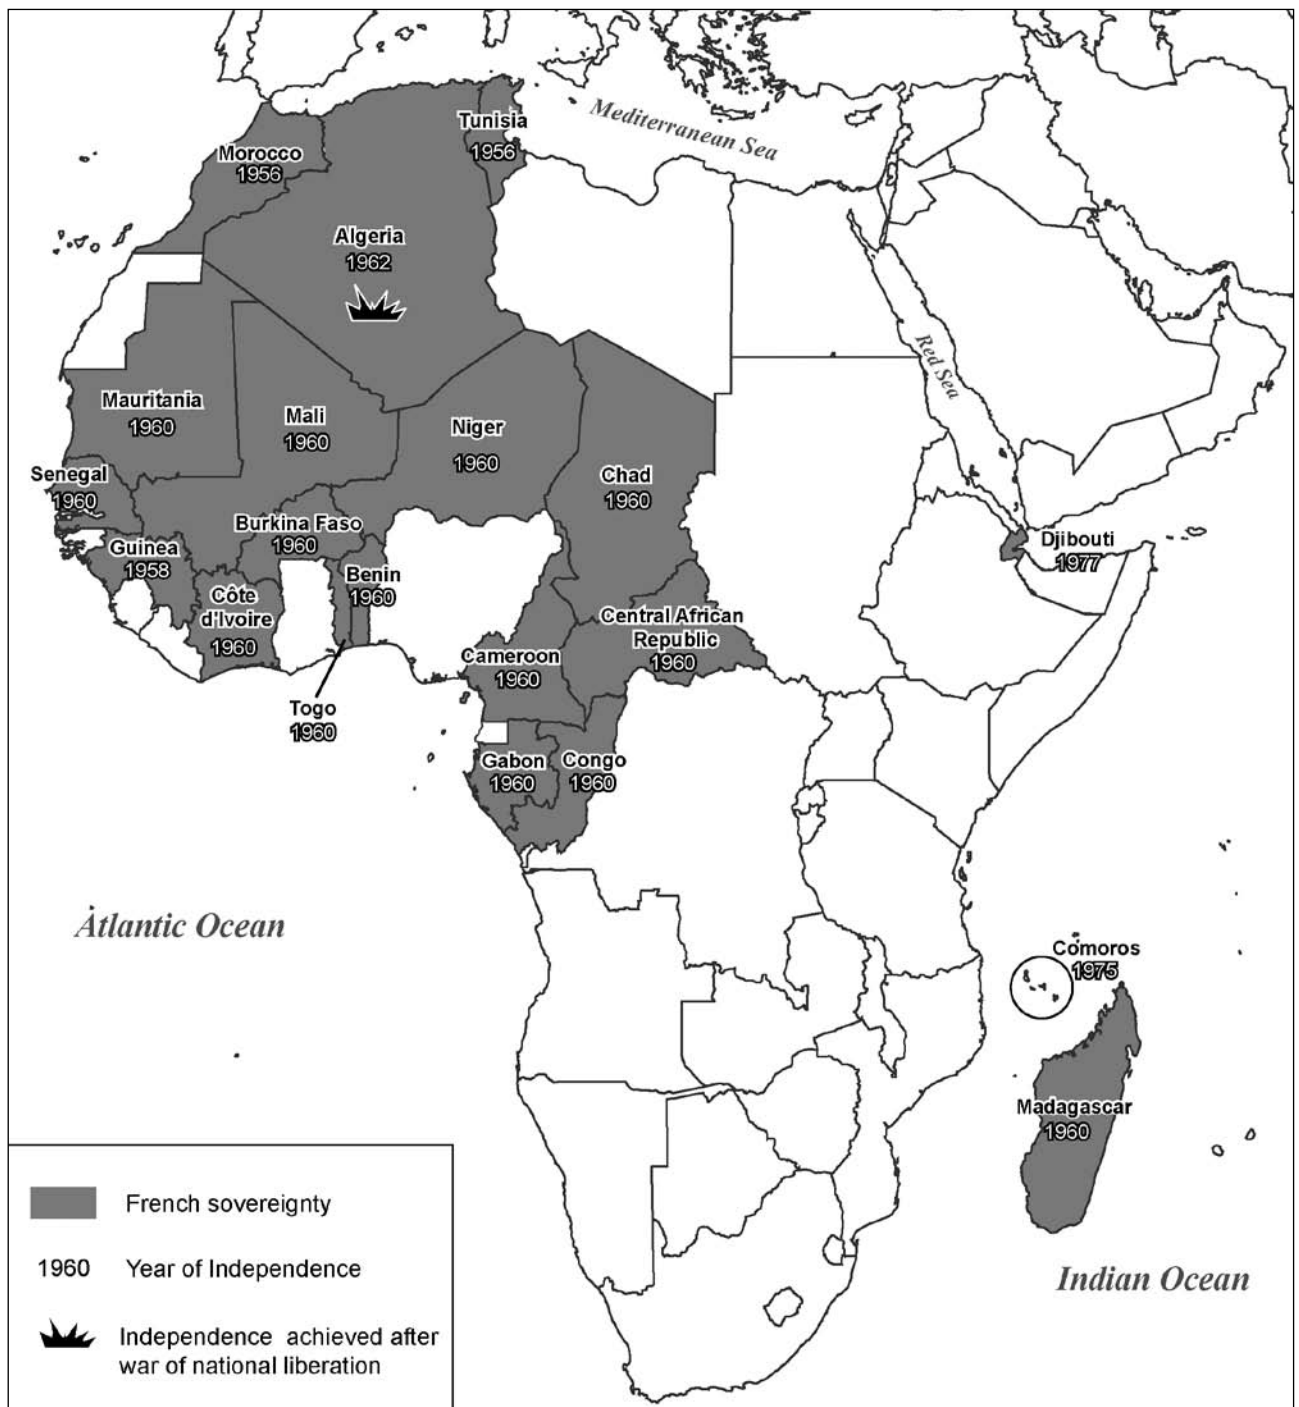
Before the end of the First World War, no clear-cut policy on colonial education emerged in France because there was no consensus on 'native policy'. The government clearly distanced itself from the mid-nineteenth century liberalism that conferred citizenship rights on the Four Communes in Senegal. Those rights were not abrogated, but there was no question of extending them to other communities. Instead of adopting the policy of assimilation, official policy began to favour 'association' of the masses through the prevalence of French language and culture. Much effort was devoted to studying Islam so as to encourage Muslims to retain their faith while embracing the French language and aspects of French culture, provided they steered clear of international Islam and radical Middle East politics. Individual ministers and colonial administrators took the initiative, generally within the context of the prevalent anti-clericalism that bred a distrust of missionary activities and the tendency to centralization that encouraged officials to seek directives from Paris.

By 1918, there was wider appreciation of the tremendous contribution of African manpower and material resources towards the French effort during the war, and of the potential role of the colonies in revitalizing the French economy. This was the message of the book entitled *La mise en valeur des colonies françaises* by Albert Sarraut, the Minister for the Colonies. Sarraut's aim was to seek 'the economic growth and human development' of the colonies, in the spirit of the new 'trusteeship' of the strong protecting the weak. Education remained the most vital instrument not only of human development, but also of economic growth. Various directives were published in successive issues of the Education Bulletins to spell out the objectives of French colonial education:

    – to expand the influence of the French language in order to establish [French] nationality or culture in Africa;
    – imperial duty and political necessity impose … [the need for] training an indigenous staff destined to become our assistants throughout the domains and to ensure the emergence of a carefully chosen elite … and of educating the masses to bring them nearer to us and to change their way of life.

In practice, French administrations did little to educate the masses. The role of French language and culture in breeding respect, support and loyalty to the French, as a way of enhancing the productivity of the masses, continued to be stressed. But, promoting French language and culture was left to the indirect effects of the French presence and the activities of missionaries in the rural areas. Far more emphasis was placed on the members of the carefully chosen elite, who were to become not only assistants, but also great admirers of French culture and loyal defenders of French colonial rule. They were to be detached from the masses, to function principally in the urban areas, preferably in Dakar,

where the vestiges of the old policy of assimilation remained, or, best of all, in Paris. Policy guidelines were to ensure that although missionaries were welcome, the educational system was to be as formulated and dominated by the state. Missionary work was encouraged largely in rural elementary schools of two to three years, teaching mostly spoken French and some arts or crafts. It was the responsibility of the state to ensure urban and regional upper elementary schools, and at least one higher primary/technical school in each colony. Such schools sent their best students to the state central secondary schools (Lycée Faidherbe in St. Louis, or Lycée van Vollenhoven in Dakar), or the

*Map 17* **French colonies in Africa**


comprehensive Teacher Training College (William Ponty). In the early decades of the century, there was some attempt at the William Ponty to encourage appreciation of the local culture.[6] There were also the Dakar School of Medicine and Pharmacy, the School of Naval Engineering in Gorée or the Veterinary School in Bamako for training assistants.

The initiative to stimulate research in colonial territories came from a few outstanding scholars who wished to extend the research interests of different French institutions to the colonies. Following in the footsteps of Louis Archinard and Captain Louis Desplagnes, scholars, such as Maurice Delafosse, Marcel Griaule, Theodore Monod, Jean Cremer and others, tried to extend the work of various Paris-based institutions to the colonial territories. These included the Museum of Natural History, the Trocadéro Museum of Ethnography, the Pasteur Institute, the School of Oriental Languages and the Geographic Society. This encouraged the establishment of local research infrastructures in Africa. As early as 1902, Gallieni was working to set up the Academy of Madagascar. In 1915, Governor Clozel founded the Comité des Études Historiques et Scientifiques (Historical and Scientific Studies Committee) for the AOF; while the AEF established the Société des Recherches Congolaises (Congolese Research Society). Each institution developed its own journal or research bulletin: the Madagascar *Notes, reconnaissances et explorations*; the AOF *Bulletin du Comité des Etudes historiques et scientifiques*; and the AEF's *Le Bulletin de la Société des recherches congolaises*.

The specific areas of focus in the growing colonial scientific infrastructure included ethnology, archaeology, health, agriculture, meteorology, and geology. The aim of the institutions at the time was to gather information and not to build up or train local scientists. The professional staff of the institutes, laboratories, observatories and networks of meteorological and geological services were almost exclusively French. Any promising African assistant was more likely to be assisted to get to France than to be encouraged to remain in his homeland. By the early 1920s, various experimental botanical gardens were established, for example, in Dabou and Bingerville in Cote d'Ivoire; Saria and Niangoloko in what is now Burkina Faso; Kati in Mali; and Brazzaville in Congo. Some of them began to specialize, like the one in Bambey (Senegal), which became famous for its work on groundnuts. It has been pointed out that often the researchers were not highly specialized. For example, the agricultural experimental stations were often manned not by virologists, but by plant taxonomists and general pathologists. Nevertheless, important breakthroughs were sometimes achieved. The precipitous fall in world market prices of groundnuts and other colonial commodities during the Great Depression halted such developments. Groundnut prices improved after 1934, and the Front Populaire initiated the era of planned development from 1936 to 1940. They expanded education, founded IFAN (Institut Français d'Afrique Noire/ French Institute of Black Africa) at Dakar, and gave research a fresh impetus. But all that was undermined by the racist policies of the Vichy Government, which abolished the citizenship rights of the Four Communes, the freedom of the press, freedom of public assembly, the right to demonstrate, and many of the social reforms of the Front Populaire.

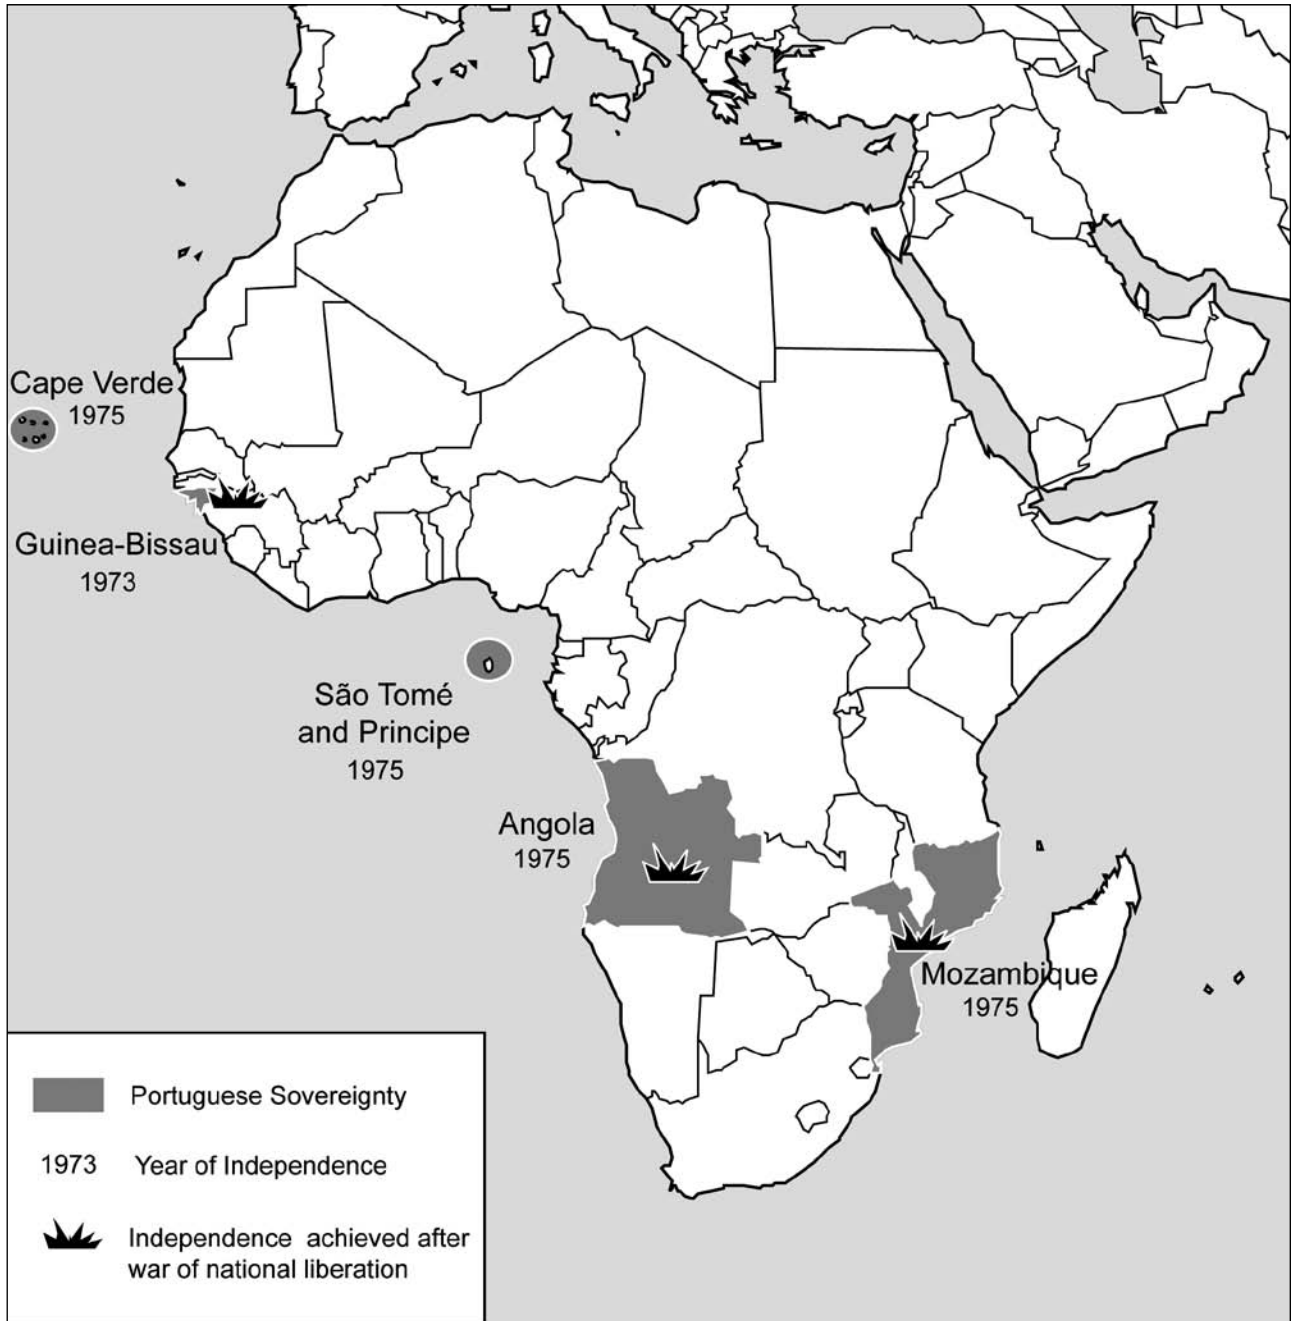
## Portugal

The long history of the Portuguese presence on the coast of Guinea, and in Angola and Mozambique produced significant communities of mestiços or Portuguese settlers, traders and officials and Africans of black or mixed ancestry. They were based primarily in the coastal cities, the largest community having settled the Cape Verde islands. The 1950 census listed 103,000 mestiços in Cape Verde, 4,500 in Guinea, 4,300 in São Tomé, 30,000 in Angola and 25,000 in Mozambique. Preserving links from the era of the slave trade and caravans, mestiços remained influential along the trade routes and had contacts with the centralized kingdoms in the interior. Portugal retained possession of vast territories without the means to establish effective occupation, not to mention the pursuit of economic, cultural and technological development. The government therefore resorted to granting concessions to various individuals and private chartered companies. Since the pre-colonial period, land grants or prazos were available for those wishing to establish plantations or exploit mineral resources. Concessions for building railways or other specific economic activities were also granted. These companies acquired extensive rights and a large degree of autonomy: they were allowed to collect taxes, mint and issue money and define development policies for the territories. All of the concessions depended on the exploitation of African labour. The system was based on the belief that Africans owed 'a moral and legal obligation to work', which meant working under the orders and in the interest of the controlling power. Access to cheap labour was the main attraction of concession seekers, who often possessed little or no capital to invest. Because Mozambique blocked access to the sea for several British territories – Malawi, North and South Rhodesia, Transvaal, Bechuanaland, Basutoland and Swaziland – a large proportion of the concession seekers were anxious to control that colony.

With several companies, agencies and individuals of different nationalities exercising power and control, Portugal was in no position to formulate and implement a well-defined native policy. In theory, Portugal maintained a non-racist policy, and the mestiços and *civilizados* were entitled to all the rights of citizens. Although they were not subject to African taxation or forced labour, they were expected to pay European taxes, which were more burdensome and more difficult to evade. They had to renounce 'African customs', give up entitlement to African communal land rights, and the possibility of becoming chiefs. Few acquired the necessary educational qualification, and many of those who did were discouraged by the procedural delays and administrative obstacles. For the vast majority of 'natives', there were guidelines for the operation of labour laws, which were eventually codified in 1929 as the Estatuto Politico Civil e Criminal dos Indigenas.

Education was in the hands of missionaries, few of whom were Portuguese: they included English Baptists, American Congregationalists and French Holy Ghost Fathers. After the overthrow of the monarchy in 1910, the Republican regime was overtly anti-clerical, and the Portuguese Jesuits in Mozambique were expelled in 1911. Other missionary societies, especially in Angola, had deeper roots going back to the nineteenth-century evangelical and abolitionist movements. They provided a few years of elementary

*Map 18* **Portuguese colonies in Africa**



education in the rural areas, some secondary education, mostly technical or arts and crafts, and the training of village teachers and catechism instructors. Missionaries, particularly the Protestants, were often harassed for being critical of government or for siding with African victims of scandalous abuse, poor administration and repression. A law passed in 1921 made it compulsory for all missionaries to be ordained ministers, all churches to teach in Portuguese, and the Catholic clergy and religious orders to be subject to Portuguese episcopal authority. Some of the concessionaries operated schools to teach reading and crafts. For purposes of acculturation, the churches were as influential as the schools, which enforced monogamy, civil laws, use of pit latrines and other facets of Portuguese social life. Cultural

and technological education was almost negligible until after the Second World War. In 1929, Mozambique registered only 30,600 pupils, mostly in rural schools, and in Angola the total did not exceed 46,000.

The Republican regime in Portugal (1910–26) increasingly encouraged the lower classes to seek employment in the colonies. This led to further discrimination against the mestiços, whose influence declined accordingly. Following an agreement with the Salazar regime in 1940, the Catholic Church received the mandate and the funding to educate the indigenous populations, inculcating European values and indirectly supporting Portuguese colonization. This led to a rapid increase in the number of pupils in schools in Mozambique.

But such measures were enacted largely for the benefit of the rising number of Portuguese settlers, who were encouraged to immigrate to the colonies in accordance with the policies of the regime. This policy in turn further increased the discrimination against Africans and the mestiços. During the Depression, thousands of Cape Verdian migrant workers were repatriated from the United States to work towards the 'development' of the colonies. In 1940, Angola recorded 44,000 Portuguese settlers, Mozambique 27,000. By 1950, the figures rose to 79,000 and 48,000 respectively. By 1960: 172,500 and 97,000; 1970: 290,000 and 150,000; by 1973: 335,000 and 200,000. For the most part, these new settlers were poor whites with no capital and few skills. They were meant to become self-reliant producers, but they quickly joined in exploiting and oppressing the Africans on the basis of an undeclared policy of apartheid. The *liceus* and rudiments of higher education that began to be established were essentially for their benefit.

## Belgium

The determination of King Leopold to reap the maximum profit from the Congo Independent State, which was assigned to him as a private estate, led to systematic abuse and international outrage. He leased the area to concessionaries. He declared a state monopoly on ivory and wild rubber. Among other abuses, Africans sometimes had their hands cut off by certain employees of commercial companies, who also burned the villages if inhabitants failed to pay taxes and produce rubber latex. At first, the outcry of Swedish, American and British missionaries was ignored. Then, E. D. Morel, a young British journalist, published a book about the 'new slave trade'. He formed the Congo Reform Association and took up the crusade in the British parliament. No longer able to ignore the international pressure, the Belgian government seized control and changed the name of the Independent State to Belgian Congo. The Belgian state was determined to carry out reforms and keep a tight control over the administration. The native policy that resulted has been aptly described as paternalism. It was a form of trusteeship that justified treating Africans as infants that needed to be guided and controlled, even to the point of enforced conversion. After 1918, the same system was extended to Ruanda-Urundi, though the substructure of German rule and the links with Tanganyika and Uganda remained close.

The Congo basin had been an attractive mission field for the evangelical and abolitionist movements of the nineteenth century, not least because of the history of evangelization and the slave trade in the area since the sixteenth century. The area attracted British and American Baptists and British Congregationalists as well as French, Italian and German Catholic orders. The Belgian state made a pact with Rome to support and subsidize the work of Catholics provided the personnel were restricted to Belgians. Only those Protestant missionaries who were licensed and operated strictly within state regulations were tolerated. The missionaries operated two-year primary schools, taught in African languages; three-year middle schools with French instruction; and a sprinkling of technical schools for training assistants in administration, health, teaching and mechanical labour. It was only in strictly controlled Catholic seminaries that future priests were allowed a higher level of education.

The tight control exerted by the authoritarian state did little for cultural and technological development. Schools operating within the triangle of such authoritarian administration, big mining and agricultural farms, and the privileged Catholic mission did little more than teach discipline and obedience. The Catholic priest used the privileged position of the Church to compel children to go to school, to encourage converts to attend catechumen classes, and to make everyone conform to moral law as laid down by the mission. The foundation was being laid for a sound system of elementary education, which was reformed after the Second World War. Meanwhile, it is not surprising that the close alliance of church and state was threatened by the Kimbanguist movement. In 1921, a barely literate evangelist of Baptist background, who responded to a persistent vision of a divine call, became a spirit-possessed prophet. He preached orthodox Baptist doctrine, but also operated as a healer, drawing huge crowds from far and near. Some of his followers were reported to have incited Africans to refuse to pay taxes and to use anti-colonial rhetoric, such as 'Congo for the Congolese'. Above all, they advocated widespread disobedience of Belgian orders, such as working for white men, sending children to school, etc. Some of them attacked a Catholic chapel that they viewed as part of the system that oppressed them. Catholic missionaries supported the plantation owners, who were losing control over their labour force, in their appeal for the suppression of the movement. Kimbangu and some of his followers were arrested. He was tried and condemned to death with no legitimate charge brought against him. This was later commuted to life imprisonment. He died in prison in 1951. In spite of this, and perhaps also because of it, the Kimbanguist Church spread rapidly and became the largest African Church in the Congo basin. Like Ethiopian religious institutions in other places, it did more than any other church in the region to mediate between Christianity and the beliefs of African peoples. It was thus a major factor of change, with profound cultural consequences.

## TECHNOLOGICAL INNOVATIONS

Colonial rule brought scientific and technological innovations in many areas of life, notably agriculture, health services, transport and communications, energy, mining and metallurgy. As a rule, these innovations were imported and not developed locally. Like European culture, such innovations were desired but had little chance of being integrated into the life of the people. As long as science was coming through Western education and culture, which remained divorced from the life of the people, there could be no growth. There was thus no effective transfer of technology except to the enclaves of British, French, Portuguese and Italian settlers in Eritrea, South, Central and East Africa. Nor was there any attempt to develop industries based on these innovations. Rather, colonial policies were meant to ensure that imported technology undermined or displaced existing crafts and industries. To some extent, assistants were trained in the trade schools or special workshops to maintain the various services, but not to improve production and quality.

## Urbanization

The effects of colonialism were felt more in the urban than in the rural areas, and the towns became the showcases of the colonial impact on cultural and scientific development in Africa. Urbanization was an important feature of many pre-colonial African societies. A few, like the Ethiopian and the Yoruba, possessed an urban culture. Most Africans preferred to live in towns and nucleated villages comprising the ruler's palace, religious centres and markets, and to travel to the rural areas to carry out farming activities. In most societies, the capitals were urbanized, especially the capitals of kingdoms and empires, such as Benin, San Salvador, and Kumasi. Such administrative centres also attracted long distance traders and resident foreigners. Other towns, such as Timbuktu, Jenne and Kano, or Massawa, Lourenço Marques and Mombasa, because of their location at the end of trade routes, river crossings, or on the coast, became market centres, which attracted crafts, manufacturing and large numbers of resident foreigners. Islam had a particular impact on many urban areas, making the populations more open to foreigners because of the long distance traders, scholars and religious leaders that they attracted. In the nineteenth century, many of the capitals in Muslim Africa had numerous administrators, judges, military and religious leaders, and itinerant scholars and students at public expense. They thus also attracted large numbers of slaves from far and near to act as soldiers and to produce surplus food and trade in the surrounding rural areas.

Colonial rule had an even more spectacular impact on urban life. It began with trading outposts, military garrisons and forts, and administrative centres established on the outskirts of existing towns or at new locations. The infrastructure of colonial rule, such as courts, treasuries, police and military barracks, were the essential features of such towns. However, the more important role of colonial cities was to serve as centres for the import and export trade, that is ports, often doubling as capital cities, railway termini, or other collecting points for cash crops. As such, banks, shops, warehouses for imported goods, and for processing cash crops for export, developed. Such centres also were often the headquarters for missionary societies, with churches, schools and training colleges of local and regional importance. People flocked to these centres as urban workers migrating from the rural areas. Because of racial discrimination, the small group of European settlers, traders, missionaries, administrators and other professional staff and their families occupied the centre of the colonial town, with specially designated suburbs for Africans, each with its separate markets, shops, churches, hospitals, and even cemeteries. Often, Africans – even the domestic staff of European households – were not allowed to stay in the 'European' towns beyond sunset. It is noteworthy that the colonial cities, unlike traditional towns, were not allowed to promote and sell African crafts and manufactured products.

Such colonial towns were important centres for the diffusion of the European urban culture and greatly expanded the cultural influence of missionaries that began to spread in the nineteenth century. The European settlements were planned according to the town-planning traditions of the different European countries – the British, with their roundabouts; the French, with cultural centres and museums, etc. Architecture also varied according to the different national styles. Although Spain and Portugal had experimented with some tropical architecture in Latin America, and the British in South India, the influence of metropolitan temperate climate architecture was initially predominant. For example, fireplaces were often incorporated in up-scale homes even though they were never used. Africans with the necessary means built in the European style, abandoning their own styles of age-old traditional architecture, which was better adapted to the climate. European building materials, particularly cement and corrugated iron roofs, were widely adopted. Bread became a staple, bakeries proliferated, and European cuisine – Irish potato and oven-cooked instead of stewed meat – was sometimes imitated. European drinks began to supplement traditional African beverages. European-style bars and nightclubs emerged, but the popular music that was influential was not European but Latin American, which was itself an urbanized version of music originally exported from Africa.

Municipal services emerged: water and electrical energy supplies, refuse disposal, etc. Initially constructed for the benefit of European officials and settlers, especially in the mining and industrial areas, electricity supply was expanded to privileged Africans in the urban areas, such as Luabo, on the Sena Sugar estates concessionary in Mozambique. In 1924, an observer reported that the company 'did not limit itself to constructing a factory; it is constructing a city' with electric generators, railway, hospital, refrigeration plant, bakery, telephone service and workshops, all built by the company.[7] Initially, the electrical engineers in charge of the planning, distribution and maintenance of electricity supplies were expatriates. Workshops were established for the training of African assistants to help maintain the high-tension wires and the generators. It was not until after the Second World War that African electrical engineers trained in universities abroad were employed.

## Agriculture

The colonial powers introduced two systems of agriculture. Without any experience in tropical agriculture, they occupied the best land in the temperate zones to develop European-type farms. They expropriated land from the Africans thus making land and the labour of landless Africans available to Europeans at very low cost. They also facilitated access to capital through the banks, using land as collateral. The farms were protected by various laws to prohibit African peasants from producing not only such export crops as tea and coffee, but also dairy products that had been the specialty of different pastoral communities.

In the tropical areas, African peasants were encouraged (and sometimes compelled by taxation) to produce crops for export. The colonial authorities took no interest in the cultivation of food crops. The methods of production of cash crops that they dictated were based upon the farming techniques of temperate climates – intensive cultivation, crop rotation, mono-culture – which disregarded, or even discouraged, the considerable accumulated knowledge and techniques more suitable to the soils and climatic conditions of tropical agriculture. These included:
- production techniques of crop rotation and inter-cropping systems for pest control;

– great capabilities in the areas of post-harvest technologies of food processing, preservation and storage, including the fermentation of sugar to produce alcohol, and the coagulation of milk protein into butter and varieties of cheese;

– considerable experience in animal husbandry and the control and treatment of animal diseases;

– expertise in hunting and fishing involving extensive knowledge of the varieties, habits, and preferred habitats of both animals and fishes.

One serious effect of colonial agriculture was the severe depletion of soil fertility and imbalances in the eco-system, which led to the disastrous spread of trypanosomiasis. More disastrous, however was the undermining of traditional scientific knowledge and skills that could have been used to contain the adverse effects. Probably the most striking example of the devastating effect of Western agricultural science, no doubt combined with other factors, is to be found in Ethiopia, where the practice of agriculture has been documented for two thousand years. There are also the accounts of several foreign travellers who, for four centuries, described the Ethiopian plateau as 'verdant' and 'salubrious'. 'It seems that in all the world there is not so populous a country, and so abundant in corn and herds of innumerable cattle', said the Portuguese Jesuit Father Francisco Alvares in 1520. The northern Ethiopian highlands, said Henry Salt in 1816, were 'so rich in water and pasturage that Europeans could scarcely imagine its beauty'.

Menelik embraced Western agricultural science in 1907 when he appointed a Minister of Agriculture 'to improve the land, produce much grain and change agricultural work … in the European method'. This was partly his response to the Agricultural Research Institute established by the Italians in Asmara (Eritrea) in 1893. In 1938, the Agricultural Institute for Italian Africa established in Florence, with its fine Library and Documentation Centre, was assigned the task of overseeing Ethiopian agriculture. Yet, the productivity of Ethiopian agriculture declined steadily. The US Technical Assistance Program, which brought in the Agricultural and Mechanical Arts College of Oklahoma (later Oklahoma State University) to apply the American land grant system, seemed to have accelerated the pace of decline. Successive famines, which caught the attention of the media in the 1970s, showed the gravity of the situation. An observer remarked in 1985:

A culture is dying in Ethiopia. A complete way of life, virtually unassailed for 3,000 years, is coming to an end. The Abyssinian high plateau, known to the Greeks as a 'cool celestial island' is rapidly turning to dust, merging wearily into the barren and stony deserts that surround it. As it does so, the human population that it has supported for so long are blowing away too. Having slaughtered their draught oxen and eaten their grain, the people are leaving for ever their eroded fields and terraces.[8]

The agriculture training provided in the schools was ineffective because it was unrelated to local farming practices and was being taught to people who regarded the very system of formal education as an escape route from the rural life of farmers to the urban environment. A number of specialized schools and experimental stations were established to train agricultural assistants and extension workers to implement government agricultural policies.

Their attention was entirely focused on export crops rather than food crops. Eventually, an Institute of Tropical Agriculture was established in Trinidad, in the West Indies. It was not until the era of decolonization that some of those trained in this institute began to raise the standard and expertise of the agricultural schools and to cooperate with the newly established universities to develop agricultural science locally. Meanwhile, indigenous methods of food processing and food preservation were ignored. Canned tomatoes, fruits, sardines and corned beef were imported without any attempt to produce them locally. In East and Central Africa, the corn meal that became the staple of the African diet was processed by European-controlled industries, and the Africans had to pay high prices for it. Similarly, the traditional machete and hoe remained the basic agricultural implements in many parts of the tropical areas, but imported tools soon replaced the ones produced by local blacksmiths. This is not to deny that colonial agricultural research has yielded some results of permanent value. Research in Africa has contributed to a more complete understanding of the complexity and diversity of natural phenomena at the global level, for example in plant science and plant physiology. Work on mycology developed across the continent yielded major collections of local mycolological materials. Many phythopathological problems of major crops, such as rubber and tobacco, have been resolved. Research on different flora of various regions of Africa has contributed much to the literature on world biodiversity. Such data on ecological diversity will be a major factor in improving African farming systems and productivity through technological innovations.

**Health care**

As in the field of agriculture, the missionaries and colonial powers created a parallel and superimposed system of health services instead of expanding the existing indigenous system. Largely because traditional healing systems were associated with various religious rites, it was assumed that, for the most part, African doctors were bogus and fraudulent. As in other areas, the loss of confidence in the power of traditional gods has resulted in a diminished interest in traditional culture, which was held together by the pervasive traditional religion and world view. Colonial authorities showed more interest in studying and controlling tropical diseases than in solving the problems of tropical agriculture. In French Africa, the network of the Pasteur Institutes, based on the principle of research as conducted in France, was of paramount importance. The first microbiology laboratory was set up in Saint-Louis (Senegal) in 1896. It was transferred to Dakar in 1913 and became part of the network of Pasteur Institutes in 1924. In 1910, a Pasteur Institute specializing in the study of sleeping sickness was established in Brazzaville. In 1934, a leprosy research Institute was founded in Bamako. In 1940, the yellow fever vaccine was developed at the Dakar Pasteur Institute, and the plague vaccine was developed at the Pasteur Institute in Madagascar in 1945. The Schools of Hygiene and Tropical Medicine in London and in Liverpool laid the groundwork of tropical health sciences in British Africa. The missionaries founded a few notable hospitals and clinics, while colonial governments established some European infirmaries and hospitals and a few African hospitals. These hospitals trained nurses and midwives and

other para-medical staff such as 'dispensers' (assistant pharmacists), laboratory technicians, etc. In West and South Africa, even by the 1880s, a few Africans had trained abroad as medical doctors, but no matter how well they performed at school, at best they were appointed as assistants to European doctors. One or two of these, like Dr. Oguntolu Sapara in Lagos, took some interest in traditional healing systems, but their work remained atypical.

European medicine made an impact especially in the control of contagious diseases such as smallpox, tuberculosis and, to some extent, leprosy. Inoculation and immunization programmes and other campaigns of preventive health care, especially in the urban areas, were widely appreciated. So were the practice of surgery and sterilization, the use of antibiotics, and the control of bacteria. Nevertheless, for reasons of accessibility and cost, European medicine catered only for a minority of the people. The two health systems remained separated because the Africans trained in European medicine have often been the most distrustful of traditional healing, and the most opposed to finding an accommodation between the two. Today, attempts are being made to identify the areas of strength of traditional healing and take advantage of them within an integrated healing programme. Such areas include:

– the concept of health and healing as involving not just the physical, but also the mental, the spiritual, and the patients' social relationships;
– psychiatry, which has been particularly enhanced by the holistic approach to healing;
– herbal cure of minor fevers, stomach disorders, etc.;
– bone-setting and orthopaedic surgery.[9]

### Transport and communication

Without doubt, the colonial period was very innovative in the development of technology in the field of transport and communication. First, there was the steamer, followed by the railways; and then the bicycle, lorries and automobiles. The technology and industry for the production of steam vessels remained abroad, but a few schools were established to train navigators and other shipping auxiliaries. Assistants were also trained to serve in the development and maintenance of the port facilities. Railways played a prominent role in the development of the import-export orientated colonial economies. Various companies won contracts or concessions to raise the necessary funds and construct the railways as cheaply as possible. Africans had to be involved in laying and maintaining the tracks, driving and maintaining the engines and coaches and operating the services. For these, workshops and training schools were established. The railways were meant to serve the economic and strategic interests of the colonial powers more than those of the Africans, and they helped the colonial power to resolve the problems of relatively low population density and dispersal of resources. As has been pointed out, they operated mostly for the export of cash crops and minerals. They ignored the internal road network. The telegraphs that were linked with the railways served the military forces and the needs of internal security and, although it was extended to commercial organizations, it was strictly for expatriate companies only. Radio broadcasting through rediffusion boxes was introduced in the 1930s, along with the laying of foundations for long distance telecommunication.

Lorries made a greater impact, especially in West Africa, where African entrepreneurship played a significant role particularly in the groundnut, cocoa and palm producing areas. They encouraged the construction and maintenance of roads, which paved the way for civil engineering projects. Assembly plants for motor lorries became a minor industry, and skilled mechanics were produced to maintain the vehicles. Because the railways were so rigid and capital intensive, they remained under strict control of the colonial authorities while lorries were more flexible and more amenable to African participation. With such African involvement in improved transportation, other developments such as passenger travel and improved postal services did not have to depend solely on conservative government policies. Air transportation to North Africa began soon after the First World War, and first crossed the Sahara in 1924. Regular civilian passenger movements did not begin until 1937 with the Imperial Airways London-Cairo-Khartoum-Johannesburg flights, with a branch line from Khartoum to Nigeria. That was the era of small associated airlines, small aircrafts, and several small airfields intended to supplement inadequate road and rail networks.

### Mining and metallurgy

Mining and metallurgy were of special concern to the colonial powers interested in investing capital and technology to exploit African resources. It was also an area where African miners had shown great skills and techniques. There is now clear evidence of widespread mining of iron, tin, copper and gold, all over Eastern Africa from the Cape to the Horn and in West Africa. Blacksmiths and goldsmiths operated throughout the continent and were held in such high regard that they constituted a sort of occupational caste. But the colonial powers, armed with their foreign capital and technology, undermined indigenous techniques and enterprise. Land surveys for settling boundaries did not only yield maps. They also sometimes identified valuable mineral resources, with subsequent mining activities across the continent: gold in the Gold Coast (now Ghana) and Angola, tin and coal in Nigeria, copper in the Congo and Rhodesia, and gold and diamond in South Africa and Angola. Licenses for prospecting and mining operations were granted to European firms and concessionaries to exclude indigenous African miners. Such European firms were able to import equipment for digging much deeper than any African miners could. Legislation was often enacted to protect imported European manufactured goods, such as guns, from local competition. Indigenous technology remained undeveloped, and local manufactures had to compete usually on unequal terms with imported tools and utensils.[10] The story was the same in other areas of indigenous technology such as glass fabrication and textile manufacturing.

## DECOLONIZATION AND APARTHEID

The Second World War broke out at the end of a decade of worldwide economic depression during which there was little room for investment in economic, cultural or scientific

development. It is not surprising, therefore, that there was a vigorous attempt to proclaim reform and renewal immediately after the end of the war in 1945. The British were determined that the 1940 Colonial and Welfare Act should be more effective than the mere gesture of the 1929 Colonial Development Act. Similarly, the French established FIDES (Fonds d'investissement pour le développement economique et social/Investment Fund for Economic and Social Development) with specific structures and programmes to make the Fund productive. After the Second World War, the Portuguese attempted to develop the colonial economy by transferring capital and introducing new development plans. At the end of the 1950s, the colonial towns of Luanda and Lobito in Angola and Beira in Mozambique expanded along with their food and textile industries. There was some international pressure that reform should be in the direction of decolonization. However, as the euphoria of the United Nations Charter and Declaration of Human Rights gave way to the politics of the Cold War, African peoples realized that they had to struggle and, in some cases, wage war to secure independence. Not only were the colonial powers ambivalent in their support for decolonization as they had been for educational development. Their linkage of decolonization with policies ranging from the advocacy of cultural adaptation with racist overtones, to rigid apartheid, gave a new twist to the perception of decolonization.

During the years of economic depression that bred fascism in Europe, right-wing fascist regimes sought to relieve the sufferings of the European poor by finding opportunities for them in the colonies at the expense of African peoples. As noted above, various schemes were conceived for massive colonization in Salazar's Angola and Mozambique, and Mussolini's Eritrea and Ethiopia. The British directed their poor to South Africa and the Rhodesias. Vichy France looked mostly to Algeria and, as much as possible, to tropical parts of Africa as well. Fascism repudiated the theory of trusteeship and institutionalized the doctrine of apartheid. This stimulated the rise of militant nationalism and a more active pan-Africanist programme committed to decolonization in Africa. Pan-Africanists and nationalists came together at the Manchester Conference of 1945 to claim the promise of the right to self-determination that was used to mobilize support for the Allied war effort. Apart from material resources, it was estimated that, in 1944, three-quarters of all the troops fighting on the French side were Africans. However, the colonial powers saw from the very scale of that support the vital contribution Africa could make to the post-war reconstruction of Europe. They thus perceived reform and decolonization as a means of linking African economies more closely to the European interests. To block decolonization, Portugal, for example, reinforced security and repression measures through its special security unit, the PIDE (International Police for State Defence). Moreover, Portugal's entry into NATO in 1949 did not change its colonial policy. The Belgians were similarly opposed to decolonization, and when forced to take measures in that direction, they ensured that decolonization would not work. The British and the French were more subtle, moving Africans towards political independence while deepening their economic, scientific and cultural dependence.

As noted above, the policies of the British Advisory Committee on Education called for adaptation of education 'to the mentality, aptitudes, occupations and traditions of the various peoples'. This was tied up with the policies of Indirect Rule, which chose to administer the peoples through 'tribal chiefs' to the exclusion of the Western-educated elite. In South Africa, where the majority of the African population were expected by law to be 'hewers of wood, drawers of water and beasts of burden' to the white populations, adapting education to the mentality and traditions of the people meant ultimately promoting 'Bantu education', separate and most unequal. Under those circumstances, for the African leaders, decolonization meant first and foremost a struggle for racial equality and political independence. Therefore, rather than reject European culture and seek a return to the pre-colonial past, the Western-educated elite embraced the colonial institutions created by the British and sought racial equality and political independence within these structures. The educated elite argued that the autocratic rule of chiefs whom the British were employing to control the peoples was disconnected from the democratic constitutions of pre-colonial states, which allowed for wide participation of families and associations. They therefore opted for the European patterns of democracy, with statutory laws and legal systems, based on the Westminster, Paris, Brussels or Lisbon model of constitutional arrangements, and the British policy of non-partisan bureaucrats in the civil service. In doing so, they embraced the idea of developing a modern sector of society based largely on the culture, science and technology of the Western world, which dominates and alienates the traditional cultures of the people. The rift between the colonial and traditional cultures constituted a major obstacle to growth and development.

In terms of cultural and scientific development, the most important single factor in the post-Second World War reforms and revival was the development of higher education based on the British, French and Belgian models and overseen by the metropolitan institutions. University institutions were established in Ibadan, Legon (Accra), Khartoum, and Makerere (Kampala) as colleges 'in special relationship' with the University of London, which controlled the curricula and granted degrees. An Inter-University Council representing the collective support of other British universities supervised the university colleges by recruiting staff and offering advice on development through quinquennial visits.

Similarly, a decree of the French Ministry of National Education enabled the establishment of overseas French universities governed by the same laws applicable to French universities with respect to admission, quality, autonomy, and the rights and privileges of academic staff. This led to the establishment of the University of Dakar in 1957, Tananarive in 1960 and Abidjan in 1964. After independence, each country negotiated agreements with France to include technical assistance to sustain the universities for a period before establishing them as national universities. Likewise, the Catholic University of Louvain in Belgium founded Louvanium (little Louvain) in Leopoldville (now Kinshasa) in 1954, while the Protestants created the University of Stanleyville (Kisangani), and the Liberals opened the University of Elizabethville (Lubumbashi) in 1956. The three were later merged in the multi-campus National University of Zaire. Long after independence, the staffs of these institutions were predominantly expatriates. British members of staff earned supplementary allowances from

the British Government over and above the salaries of the colleges' African staff. The number of students was restricted, and the range of subjects covered was also narrow, with an emphasis on the liberal arts, humanities and basic sciences rather than developmental subjects like the social sciences, applied sciences and technology. Their basic function was to produce trained manpower to replace expatriate staff in educational institutions and the civil service, and, only marginally, in production and development in the private sector.

The new university colleges were centres of cultural development and prepared the way for eventual incorporation of African material into their cultural programmes. They established departments of African Languages and Linguistics and Centres or Institutes of African Studies for the collection and analysis of oral literatures, religious ideas, philosophies, etc. But, as in Britain, the university colleges placed culture on two levels: a popular culture still predominantly oral and spontaneous for the mass of the people, and an elitist one, based on the written texts of European literatures, from which a university-inspired African Literature in English, French and Portuguese evolved. It was the products of the departments of English language and literature, and modern European languages – that is, French, Spanish, Portuguese, German or Russian – rather than of African languages and linguistics that, for the most part, produced new African literature. Many black African writers became famous for their contributions to African literature in European languages, and one eventually won the Nobel Prize in Literature (Nigerian Wole Soyinka in 1986). It could also be argued that they had, in the process, ensured that English, French and Portuguese would be counted among African languages.

It is noteworthy that Italian is not included in the list of European/African languages, because it did not succeed in displacing Amharic and Somali as the lingua franca. This held great significance for the cultural and scientific development in the countries of the Horn of Africa. The duality that exists elsewhere – elite culture in European/African languages vs. popular culture in indigenous African languages – poses the problem of the future of the indigenous languages and their role in development. It should be observed that some of these African languages – Hausa, Yoruba, Igbo, Peul/Fulah, Kiswahili, Sotho – are major languages spoken by 10 to 20 million or more people across several national boundaries. Adopting European languages as the lingua franca creates a problem of cultural identity, but it also solves the political problem concerning which indigenous language to select out of many. Some argue that maintaining European languages as the lingua franca facilitates international connections and the establishment of a Western scientific culture. Others, using the Japanese experience, claim that education in a foreign language encourages imitation and inhibits true creativity. A scientific language needs to be developed in the indigenous language if the tension between the working language and the thinking language of the scientist is to be eliminated, and if scientific and technological development is to become assimilated.

Concerning the fields of culture and media, graduates of the university departments of European languages taught in secondary schools, but also began replacing expatriates in broadcasting and journalism, cultural management, public relations and advertising. The art councils initially recruited traditional dance troupes from the rural areas to perform at national festivals before they began to organize and train troupes of their own and encourage the emergence of an urban-based popular theatre in African languages. Radio and television have been very useful in propagating popular urban culture, particularly music. At the same time, individual Africans, also encouraged by radio and television, have made notable contributions to classical music both as composers and performers. Only one major Kenyan writer (Ngugi) has rejected the dual culture and, after he had made his name as a writer in English, began to write and produce plays in Gikuyu. In Sierra Leone and Nigeria, university departments of theatre arts tried to bridge the gap by producing plays in Krio and pidgin English, which had a greater appeal and could support a travelling theatre performing to wider audiences on playing fields and open halls. The situation created by the doctrine of apartheid in South, Central and East Africa did not favour the separation of culture into popular and elitist. To a great extent, racism forced African literature – whether in African languages or in English – to adopt a political commitment. Literature had to be directed principally towards mobilizing and motivating the masses, except in the case of writers in exile whose readership was primarily the international elite community. Africans writers such as Amilcar Cabral and Agostinho Neto, who studied at the Caso do Império in Lisbon and founded the Centro de Estudos Africanos in the 1950s, became pioneers of the nationalist movements in the Portuguese colonies through their efforts to diffuse creative literature firmly rooted in the African continent. This direct involvement of literature in political action was the basis of Ngugi's experiment, which was also responsible for forcing him into exile.

Racial discrimination was a factor in the development of sports, and it partly explains the attraction of European sports for Africans. The more they were oppressed and discriminated against by the Europeans, the more Africans regarded sports as an essential part of the culture of Europeans, necessary for the relaxation of all those claiming to be civilized. The schools propagated European sports. Educated Africans learnt to excel in many different European games like cricket, soccer, athletics, hockey, handball, etc., while ignoring and despising their own traditional, sports like wrestling, palm tree climbing, and heap making.

The universities provided many opportunities for the development of the basic sciences. Qualified staff, mostly expatriates, were employed to teach Africans at the undergraduate level and, for those aspiring to university careers, also at the postgraduate level. The laboratories were adequately equipped for basic investigations in the chemistry of local materials, surrounding atmospheric physics and the biology of tropical plants and animals. This period witnessed the creation of numerous national and regional scientific research and technological institutions in many countries. World-class research was carried out in a number of them.[11] Initially, the scientists working in them were predominantly non-Africans, as the products of the universities were deployed into teaching and government research institutes and laboratories. Eventually, African scientists trained abroad and locally began making significant contributions. Notable achievements were made in the basic sciences, including pre-clinical sciences.[12] Likewise, advances were

also made in the fields of applied science – agriculture, veterinary health, and human medicine – and particularly in the study of soils and plant genetics. The most obvious gap was in technological education. The majority of engineers were still trained abroad, more in civil rather than electrical or mechanical engineering, and predominantly for posts in the civil service. Industrial engineering was slow to develop, and the private sector businesses and industries tended to import their own specialists and did little to encourage the transfer or local development of technology.

The exploitation of mineral resources was the only rapid means for some African countries to bypass the slow and laborious process of economic growth through agriculture. About one-seventh of the entire world's ore deposits are believed to be found in Africa, and many of the African mineral deposits rank as the major deposits of their type in the world. A considerable amount of prospecting and exploitation was accomplished in many African countries during the period of decolonization. This required an understanding of the basic geology, structure and environmental factors in the region. Geological research has been difficult and expensive due to the forest cover or the sand or laterite layer in many areas. The chances of finding minerals have, however, been increased in recent years with the improvement in prospecting methods due to new techniques of geophysics and geochemistry. This stimulated research in the departments of geology and physics in the university colleges.

The minerals of South Africa have made it one of the richest countries in the world, and undoubtedly, science and technology have contributed enormously to this development. However, little progress was made until the period of decolonization in Africa and apartheid in South Africa when the Research Organization of the Chamber of Mines decided to promote research locally to improve mining technology. It became clear that the mining system employed in the gold mines was outmoded. Since no large mining fields anywhere in the world had geological conditions similar to those in the Witwatersrand Basin, manufacturers of mining equipment lacked incentives to develop mining systems for such conditions.[13] When the directors of the mining companies were persuaded of the value of the contributions of research engineers and scientists, a concerted attempt to modernize the technology of the industry took hold. Local studies of rock mechanics, heat flow, rock breaking and related subjects were intensified. The ultimate aim was to control such problems as silica dust, 'the scourge of miners', so as to achieve better, safer and more rewarding working conditions for the thousands of men who laboured underground each day and, at the same time, to improve the profitability of the mining companies. Through the introduction of new, sophisticated technology, it was possible to extend mining to depths previously thought dangerous and impossible. However, as in the colonial period, the research and technological development in South Africa remained with the whites, and the blacks were excluded. The important point, however, was that improved technology was sought locally in Africa, and the exclusion of blacks could not be total or expected to last forever.

The copper mining industry, for example in Zambia, faced many problems similar to those of gold mining. Progress was made possible by exploiting developments in science and technology from abroad, without the capacity for self-reliance. Namibia, previously a colony of the white authorities in South Africa, is one of the world's greatest producers of diamonds. The work of mostly South African consulting engineers and geologists set the stage for major developments and large-scale innovative diamond mining, after the end of the Second World War, based on one of the biggest continuous Earth-moving operations in the world. In the 1960s, Angola's rich mineral resources were further exploited when Gulf Oil began research and extraction of oil in Cabinda, and huge sums were invested in gold mining in Cassinga.

In many African countries, this period also saw an increasing demand for electrical energy, both for domestic and industrial purposes. In its principal rivers, the African continent possesses the greatest hydroelectric potential in the world but one that cannot be exploited without access to science and technology. Some progress has been made in the building of hydroelectric projects, including one of Africa's largest man-made dams, the Kariba Dam on the Zambezi River between Zambia and Zimbabwe. The technology for these dams was, for the most part, imported from abroad, usually under contracts which provided for the recruitment and training of local maintenance staff. The dam projects also stimulated research and training in hydraulics and water engineering in a number of the universities.

Developments in the field of telecommunications overseas have inevitably found their way into Africa. Thus, after the Second World War, the telephone networks were extended and improved both by the transition from manual to automatic exchanges and by installing trunk lines in the colonies. In addition, the traditional telegraph technique was considerably improved by the introduction of the teleprinter, and the modest beginnings of telex networks were developed.

## ADVANCES IN POST-COLONIAL AFRICA

The decade of independence (1960s) produced much optimism for major advances in cultural and scientific development throughout the continent. There was optimism within Africa and considerable goodwill in the international community, which promised to extend substantial economic and technological support to the newly independent countries. But this assistance also tended to increase the degree of Africa's dependence on the wider international community. When the world economic climate worsened, and the politics of the Cold War reached dangerous levels, the amount of goodwill diminished, and the consequences of dependence became apparent in massive national debts that placed the African economies under the control of the 'advisers' from the international agencies. The overall economic decline was rapid, sometimes amounting to a crash, producing political instability if not outright structural collapse.

The countries that became politically independent realized the value of cultural awareness and, to some extent, the interaction between culture and development. There was thus some cultural revival in the use of national dress, names, food, and attempts to come to terms with traditional cultures in the pursuit of innovative change; but such attempts were often not wholehearted or effective. In

countries where independence was not readily forthcoming and liberation wars had to be fought, cultural awareness was a vital weapon in the struggle, particularly for mobilizing the people. However, as soon as independence was won, the former colonial power was transformed from enemy to the most important trading partner and technical assistance donor. In Zimbabwe, Namibia and South Africa, the settlers, rather than Britain, were the real enemy; and cultural links with Britain have remained an essential factor in the race towards development. Thus, it was soon evident that, whether independence came quickly or not, the pursuit of 'modernization' or 'development' in a state of economic and technological dependence could not be undertaken on the basis of cultural autonomy; technology, industrial plants, managerial skills, and whatever was borrowed from abroad, came not only with an economic tag, but also at a cultural price. Western culture continued to make its inroad via the mass media, especially television, school and university textbooks, industrial manuals and handbooks, etc. In their works, African writers explored different angles of the cultural situation and the contradictions between the values of the culture of the modernizing elite and the traditional cultures of the people. They may even have exaggerated the psychological pressures on the elite who had to live and operate within the two contradictory cultures. After a while, they began to move beyond the theme of the clash of cultures, as they became increasingly critical of the divisions, mismanagement, and abuses of human rights, etc., within the new states.

African countries tried to use the pursuit of excellence in sports and culture as instruments in the search for national and continental unity as well as to gain international recognition and acclaim. French-speaking countries in West Africa announced a 'ten-year plan' for the systematic study of oral traditions and the promotion of African languages as media of culture and instruments of life-long education. They sought the cooperation of UNESCO and the OAU (Organization of African Unity) in the establishment in Niamey, Niger, of a multi-cultural Regional CELHTO (Centre for Linguistic and Historical Studies based on Oral Tradition) devoted to the collection and publication of oral traditions and folklore. The Centre for Applied Linguistics was set up in Dakar, to work with departments of linguistics and oral literature in IFAN and the local branches of the former IFAN. Another body supporting local traditions is the CIEPAT (Inter-State Centre for the Promotion of Artistic Crafts and Cultural Tourism) at Abomey, the ancient capital of the kings of Dahomey. Biennial crafts fairs were held at Wagadugu for a number of years to promote handicrafts such as jewellery making, fabric dyeing and dress designing. Also noteworthy were the Dakar Biennale as the established venue for the African art market, while the biennial Wagadugu Pan-African Film Festival has continued to attract increasing international attention. Similar projects in other parts of Africa have also had some success in stimulating traditional crafts, and modernizing their technology. In this way, some African designs, such as the women's wraparound skirts, men's *dansiki*, and kente fabrics have entered the international market. The efforts at regional cooperation resulted in the Dakar World Black and African Festival of Arts and Culture in 1966. However, underfunding and management problems have hampered the growth of many of these institutions and cultural initiatives.

Within the framework of its Convention for the Safeguarding of the Intangible Cultural Heritage (2003), UNESCO has recognized several African traditions as masterpieces of the Oral and Intangible Heritage of Humanity. These include the traditional skills of the Zafimaniry community in the highlands of Madagascar, the cultural space of Sosso-Bala in Guinea, the oral heritage of Gelede in Benin and the oral traditions of the Aka Pygmies of Central Africa.

Nigeria tried to promote national unity through annual festivals of arts and culture, as well as national competitions in soccer and athletics championships. After emerging from the throes of civil war and thanks to the boom in oil prices arising from the Arab-Israeli War of 1973, Nigeria decided to stage the World Festival of Black and African Arts and Civilization (Festac) in 1977 as a follow-up to Dakar 1966. This festival, and several others, attempted to link development to culture, in the search for ways to exploit the culture of the people in order to establish the necessary base for modernization and development, even in the areas of science and technology. There is little doubt that considerable success was achieved in raising worldwide awareness of the quality of traditional African art and contemporary African literature. Similarly, African athletes, especially in long distance running, have won international acclaim, and African soccer teams have also made their mark. The degree of success achieved in using sports and culture to promote national or continental unity, or provide a secure cultural base for modernization, is more controversial.

As noted above, higher education, and the universities in particular, have been crucial to the development of culture, science and technology, and international support in the immediate post-independence period was most notable in these fields. The universities consolidated the achievements of the decolonization period and built upon them to meet the needs of cultural, scientific and technological development. The expansion and creation of African scientific and technological institutions – not only the universities, but also governmental research institutes, regional organizations and programmes – worked well in the period of relative affluence following independence. There were, thus, records of substantial scientific and technological achievements in post-colonial Africa. For example, in the field of agriculture, attention turned from cash crops to food crops. A number of research institutes at the national, regional and international level have been established and are conducting crucial agronomic studies and carrying out research on new plants and crop varieties, as well as improving production through genetic engineering. For example, the International Institute of Tropical Agriculture (IITA) at Ibadan, Nigeria, has made significant improvements in the production of African food commodities such as cassava, yams, maize and cowpeas, rice and sorghum. A number of institutions have been conducting research on water resources and their exploitation to enhance agricultural production. Others have pursued research on animal diseases and livestock production, as well as on African farming systems generally.

Post-colonial Africa was able to exploit the ideological struggle of the Cold War by sometimes playing one side against the other, when its demand for technology seemed likely to be ignored or rejected. Thus, Western capitalists refused to build the Volta River Dam for Ghana under

Kwame Nkrumah, until they realized that Czechoslovakia was ready to accept the job. When they refused to build the Aswan Dam for Egypt, the Soviet Union had to come to the rescue. Similarly, when the building of a railway from Tanzania to Zambia was obstructed, the socialist state of China stepped in in a show of solidarity with African peasants and workers. The two largest Portuguese colonies, Angola and Mozambique, embraced Marxist ideology, particularly in the early years of independence. In Angola's long civil war, the MPLA (Movimento Popular de Libertaçao de Angola) was heavily supported by the Soviet Union and Cuba.

Imported technologies provided by non-African allies greatly contributed to local communities as the level of science-based education rose. It is not surprising, therefore, that local geological survey departments, sometimes advised by foreign consultants, use the latest prospecting techniques to increase knowledge of mineral resources of all kinds in Africa. Recent improvements in geophysical and geochemical techniques have facilitated the discovery of new resources of rare metals and minerals for which new industrial uses offer an expanding market.

There has been some progress in the area of civil engineering for the construction of roads, railways, airfields, causeways, bridges, dams, high-rise buildings, etc. Such achievements have been made possible through research into the problems of structural design and constructional material, and adequate knowledge of the terrain, moisture content of the soils, the structure and nature of underlying rocks, and the depth of sound rocks below the surface when deciding on foundations for bridges, etc. All these are highly technical matters, requiring the combined efforts of the engineer, the geologist, the physicist, the chemist, the geographer and the pedologist. They thus require the application of science and technology and the exploiting of continuing innovations in meteorology and civil aviation in the world.

There has also been an increased demand for telecommunications services and facilities in Africa. National capitals, with their distinct political, economic and cultural conditions, have grown out of the 'remotely controlled' administrative capitals of the former colonies. The new capitals now host diplomatic missions from all over the world, which require efficient telecommunications systems. The growing press and news agencies make greater demands on telecommunications installations. Equally important has been the emergence of a new African executive class with the increasing need for telecommunications facilities consistent with their new lifestyles. Anglophone Africa, like the rest of the continent, thus continues to benefit from the accelerating advances in the communications field, and one can now find increasing use of new equipment for automatic telephone dialling, telegraph, telex, facsimile, e-mail, as well as use of satellite and Internet facilities. Similarly, in the energy field, hydro-engineering to harness hydropower has come to stay; while in the oil industry, the need for fuller exploitation of solar power, biogas, etc., and the production of coal briquettes have brought about new and exciting opportunities for Africa's scientific and technological development.

Local technology, particularly relevant technology, is also being generated as a result of the acquisition, innovation and adaptation of imported technologies to local conditions. Some transfer of technology is achieved through the acquisition of new machinery and equipment, maintenance services and on-the-job training. Along with Anglophone Africa, many other African countries have invested or been made to invest huge amounts of money in the acquisition of sophisticated scientific equipment for research in educational institutions and the provision of agricultural and health services. Such equipment requires regularly maintenance and repair. Unfortunately, the facilities available in many parts of Africa for proper maintenance are grossly inadequate. As a result, much apparatus is out of service for long periods of time, and large capital investment in expensive instruments and equipment is placed at risk. For research institutions, it is difficult to organize the research work and programmes and plans often have to be modified or aborted. This state of affairs is a direct impediment to the building and development of sound scientific and technological infrastructures in these countries.

Crises have sometimes acted as a spur to development. For example, scientists and engineers had some remarkable achievements in Biafra during the Nigerian civil war (1967–70). In the manufacture of weapons, electrical engineers and chemists working at the Products Development Agency (PRODA) made hundreds of mortar bombs, land mines, anti-aircraft rockets capable of flying some 2 km, hand grenades like the famous Ogbunigwe, and the armoured vehicle 'Genocide', which was built in Port Harcourt. At the forefront were civil engineers, who had to construct runways for airports. Within only four weeks, the Uli airstrip was constructed, with an air traffic control unit on wheels. As the civil war heated up, it handled the largest air traffic on a daily basis in the whole of Africa, with the possible exception of Johannesburg, and over 90 per cent of the traffic occurred at night time. They succeeded in building out of entirely locally fabricated materials a giant petroleum refining facility and thereby made the technology so diffuse and more universally understood and applied than anywhere else in the world. They also produced cement and used bamboo sticks as fractionalizing columns. Such seemingly impossible tasks were accomplished with dispatch, as when civil engineers had to wade in floods to build a three-mile pipeline from Eghana oil field to the outskirts of Oguta. Unfortunately, these were not followed up at the end of the civil war.

Apartheid had a similar impact on scientific and technological development in South Africa. During the period of international isolation, South Africa achieved significant scientific and technological breakthroughs in certain fields to ensure its own survival and integrity, though without the involvement of the majority black population. Isolation spurred direct investment meant to boost self-sufficiency in technology in several key industries, especially the automotive, oil refining and petrochemicals, telecommunications and computer industries. South Africa has no known oil or gas deposits. In order to achieve energy self-sufficiency in the face of increasing political isolation, in the early 1960s South Africa initiated measures to reduce the country's dependence on foreign oil and consequent vulnerability to a cut-off of supplies.[14] One of these involved the production of synthetic fuels. The country was able to make a major breakthrough in the conversion of coal to liquid fuel and other substances. Such processes were probably better established and more advanced than in most other countries where petroleum-based industries were predominant. Now a world leader in

the development and application of oil-from-coal technology, South Africa operates one of the world's few successful coal-gasification programmes. Not only is South Africa a major producer of uranium, but it invented and oversaw nuclear enrichment technology with the assistance of its erstwhile friends in the West. South Africa remains dependent on Western technology for the continued development of many of its strategic industries. The country's dependence on foreign technology is most evident in the areas of sophisticated electrical equipment, scientific instrumentation, computers, and nuclear energy. However, it has also become a modest exporter of technology. There has been some interest in the United States in the proven but expensive South African coal-gasification technology, as well as in its deep-shaft mining technology. South Africa's other exports in older technologies in agriculture, mining, and manufacturing are of particular interest to the states of the southern African region.

## PROBLEMS, SETBACKS AND PROSPECTS

The so-called African crisis has hit hardest in the realm of culture, science and technology. The optimism and promising indicators of development visible in most African countries in the 1960s and 1970s have given way to stagnation, if not regression and decay. This has been manifested in political instability throughout the continent and occasional structural collapse of the state system, including the decline of the educational system, available infrastructure, industries, and in general productivity and revenues in the face of rising inflation and unemployment. The methods by which most African countries have been trying to cope (e.g. one party state, military intervention, and even structural adjustment, privatization and so-called democratization) have complicated rather than alleviated the problems.

When we consider the entire African continent, it is clear that the crisis has produced a social, economic, cultural and political environment that presents a series of impediments to fruitful scientific and technological development. These include: (i) widespread superficial understanding of, and lack of political commitment to, science and technology (S&T) among the government leadership; (ii) the consequent marginalization of the national scientific and technological communities, as well as their achievements and capabilities; (iii) little public awareness of the importance of a strong scientific and technological capacity; and (iv) insufficient public and private demand for S&T. Competent scientists and technologists in many African countries are unable to maintain desirable contacts among colleagues. The institutions and opportunities that could facilitate such contacts are either grossly inadequate or, in some cases, simply non-existent. When good minds are so few and so scattered and unable to meet and stimulate one another, they lose the courage to persevere.

In a number of African countries, political instability has led to upheavals, ethnic conflicts and civil wars, in which the infrastructures of institutions for intellectual, scientific and technological work have been destroyed or abandoned. Such events have prevented many specialists – academics, scientists, technologists, etc. – from pursuing their

professional calling within their own countries. Finding that they can no longer carry on their scientific, technological, or scholarly work in a physically safe environment or with any degree of professional integrity, they are forced to seek safe havens elsewhere. These, together with the problems of insufficient and uncertain funding, are some of the major factors driving Africa's highly trained and skilled brainpower into DESSA (Distressed and Expatriate Scientists and Scholars from Africa) situations. These same barriers prevent new recruits from joining national institutions. The DESSA phenomenon, including the pervasive 'brain drain', poses monumental impediments to the scientific and technological development of Anglophone Africa and of the entire continent.

The national research systems set up with the support of donor agencies over the past 30 years have not, by and large, been able to sustain effective performance. Moreover, they often have a narrow focus and are aimed primarily at short-term solutions to specific problems rather than at strengthening African capabilities to solve general problems. In some cases, they have created an isolated research without a broad base of technically trained and experienced personnel. Moreover, a science-based culture in suitable technology adapted from the international centres to a receptive peasantry has not emerged. Unlike university research, their work is seldom subjected to peer-review scrutiny, and this has sometimes led to mediocre results. Their budgets have generally been drastically cut in response to government revenue shortfalls, and although their budgets may look adequate on paper, there is actually seldom money for equipment, periodicals, fieldwork, or anything else beyond salaries, which are frequently not paid on time. The systems have been able to retain competent personnel only as long as better opportunities were not available elsewhere. The entire apparatus of government research has tended to collapse whenever donor support was phased out.

By the 1970s, many African countries had established bodies that, at least officially, had comprehensive responsibilities for developing science and technology policy, which cover the gamut of government measures necessary for augmenting the nation's scientific and technological capacities and adapting them to the process of economic and social development. However, the dominant approach used in designing those organizations was to imitate bodies responsible for 'science policy' or 'science and technology policy' in the developed countries. Not surprisingly, the scope of the institutional 'clones' set up in Africa was usually too narrow for the needs of African countries – limited essentially to resource allocation to different areas of research and development.

To complicate the problems faced by individual organizations, the overall structure of scientific and technological institutions for exploiting the potential of science and technology in Africa is usually disarticulated and functionally incoherent. 'For example, even where excellence is achieved, scientific research too often seems weakly linked to technological development. In turn, technological research and development, whether in universities or specialized research organizations, has generally remained functionally disconnected from the use and application of technology in agricultural and industrial production'.[15] In most countries, this also applies to industrial production. But even in agriculture, research has

had a very limited impact on the technology used by farmers – except in the case of a few crops in specific geographical areas. Agricultural research is often carried out with little direct collaboration with farmers; and institutions concerned with education in agricultural technology have little to do with the training of farmers who use that technology.

Africa's problems in developing coherent institutional structures for exploiting science and technology in production are not, of course, unprecedented. Very similar problems had been experienced by other societies. Indeed, the earlier experiences of those other societies had several features in common with the current experience of Africa. 'As they sought to accelerate industrial and agricultural growth, all of them had weak scientific and technological capacities. All of them had to create new institutional structures and new human resources in order to exploit the potential of science and technology. They all had to overcome their scientific and technological weakness in an international context in which other societies had already established dominant economic, technological and scientific strength'. Arguably, Africa faces an unprecedented task, as none of those other more developed countries had sought to overcome their scientific and technological backwardness in the context of late-twentieth-century science and technology.

Issues about developing the 'human capital' needed for industrial development have not, of course, been ignored by policymakers and their advisers. But policy concern about those issues has been somewhat circumscribed. It has tended to focus principally on allocating resources to the education and training infrastructure, i.e., on the development of institutions that will generate human resources for industry. Furthermore, it has centred primarily on the development of human resources for using and operating given technologies, not the resources required to generate and manage change in those technologies. Development and the accumulation of industry's human resources for generating, absorbing, and managing technical change have fallen through the yawning gap between 'science and technology policy' and 'economic policy' as presently conceived and practised.

Several cases illustrate this point. When the copper mining industry in Zambia was nationalized, little was done to train Zambians in creative engineering to the levels of expertise attained by their former expatriate managers. Another example of insufficient intra-company training of African engineers can be seen in a range of industries in Kenya (e.g. sugar, railways, cement, and metalworking). With few exceptions, even the training provided for operating, maintaining and managing existing production systems was fragmentary and unrelated to specific tasks or skill-development programmes. As for training that might equip African engineers with the capacity for improving existing technologies, it was almost totally absent. In many African countries, the growth of relatively large-scale textile manufacturing has been a significant component of industrial expansion. But a number of studies have indicated that, after two or three decades, the growth of the industry's production capacity has been accompanied by little or no growth in its technological capacity. For example, in the United Republic of Tanzania, there was no acquisition of higher-level expertise in management, let alone in areas such as textile engineering, fibre technology, or textile chemistry.

Even more gloomy prospects are in store from the likely impact of a number of technologies taking shape in industrially advanced countries today. These include *biotechnology*, which promises to undermine African biodiversity through alternative production of transgenic species by gene cloning and other means; *biomaterials technology*, which promises to undermine the export position of non-agricultural export products crucial to a number of African countries; *micro-electronics* will probably undermine the comparative advantages of cheap labour that previously induced trans-national corporations to locate industrial production units in Africa and other Third World countries; and the computer-assisted technological advances that are rapidly and extensively changing *communication and information systems*, offering great potential only for those countries able to take advantage of them. Such changes confirm the need to develop scientific and technological capacity to enable African countries to participate and reap benefits from the new technologies, rather than remain their victims.

Some new technologies, such as solar energy and energy from biogas, are likely to exert beneficial effects on African economies and societies in the long run, but they may be damaging in the short- to medium-term while national capabilities for their adaptation and beneficial use are being built up. The United Nations Office for Science and Technology for Development has been spearheading a project to design, install and test alert systems. The aim is to give early warning to policymakers and planners in Africa, as to which of these far-reaching developments might affect such countries adversely or which, if adapted quickly enough and exploited, could be of great value. It is clear that no matter how well an alert system is designed, the crucial point is the quality and scope of national capabilities for response, as well as paying attention to environmental sustainability in the face of development options. The quality of such response will depend not only on the government and the civil service, but also on institutions of higher education, R&D organizations and, above all, on local entrepreneurs.

## CONCLUSION

Many people often fail to see the relationship between culture and the development of science and technology. Development implies the healthy growth of a society, and culture is the life of the society. One cannot achieve scientific and technological development if it is pursued as an end in itself. When science and technology are imported from abroad, it remains foreign until it is integrated into the culture – that is, the everyday life – of the people. Education is the process by which integration takes place and growth is stimulated. The political will required to provide the motivation and the direction of development, as well as the economic sinews, are based within the culture.

The colonial legacy in Africa has created a modernizing sector of society that is dependent on the culture, science and technology of the Western world and is alienated from the traditional culture and technology of the people. The dangers of this cleavage as a barrier to development has been pointed out again and again but, because of much talk and less action, little has been achieved. Africa has so far failed to outgrow its colonial legacy of dependence and

disorientation. Africa therefore remains not only dependent but also backward, and this is most obvious in the area of science and technology as well as in the field of cultural development, which remains crucial in the struggle to overcome the current technological backwardness and the widening gap between Africa and the rest of the world. It is only through an understanding of the proper relationship between culture and development that Africa can hope to reverse the current tendency towards imitation and to re-establish links with its creative and inventive spirit in order to encourage innovation and creativity.

There is no easy answer to the problem of cleavage between Western and traditional culture. While elite culture seeks to come to grips with practical science, and the application of scientific knowledge in agriculture, medicine and technology, popular culture remains suffused with beliefs in the occult, the supernatural, and the reality of myth. There has been some attempt to codify these beliefs and promote para-psychology, occultism, magic and, perhaps, even sorcery as 'an African account of nature and how it works … which could replace the so-called Western sciences'.[16] Yet just as the African approach to holistic medicine has now been generally accepted in the West, so are modern studies of complexity, chaos and instability redefining the nature of Western science itself. These studies are breaking down the barriers between social and biological sciences, and between religion and science, and science and the humanities, in the manner of traditional African beliefs. Perhaps further research into the patterns and connections of African thought and beliefs, such as Robin Horton and others have been exploring, might give rise to the theoretical framework for a coherent logical system to unite African philosophy, religion and science. Western science and technology could play a role in such an inquiry and help to bridge the gap between popular and elite culture in Africa. However, because of the colonial legacy, African governments have chosen the university-based culture and the science and technology of the West as the path to modernization and development. The task is to follow this path with greater commitment and professionalism and carry the masses along, while seeking a balance between 'African science' and Western science and technology that may lead to an African renaissance.

## SOUTH AND SOUTH-EAST ASIA

*Dhruv Raina and Syed Irfan Habib*, coordinators

## INTRODUCTION

*Dhruv Raina* and *Syed Irfan Habib*

The colonization of South and South-East Asia was completed by the end of the nineteenth century. The processes of decolonization of the two regions were well underway by the mid-twentieth century (Map 19). Until that time, several Western colonial powers had shared dominance over the two regions: Great Britain ruled the Indian subcontinent and Sri Lanka, while the Netherlands controlled Indonesia, and the United States dominated the Philippines. Thailand, the region's sole sovereign nation, had to invent a number of ingenious strategies in order to maintain its sovereignty. The two regions shared common experiences as modern science and technology emerged. Nevertheless, their distinct historical and cultural locations shaped the institutionalization of modern science in these nations along different lines. As these nation-states emerged from decades of anti-colonial struggle, their paths to modernization revealed a variety of political and cultural complexities. The modern structures of generating knowledge, such as the university and the scientific institutes that had emerged in Europe, occupied a primary place in the projects of these new states, marked as they were by their regional cultural particularities.

Modern universities and research institutes took root in India at least three decades earlier than in other parts of South-East Asia. Following the partition of British India, India inherited most of the scientific institutes and the universities. This advantage was reflected in the creation of scientific institutions and practices that were relatively stable well before India became independent. The formal end of colonial rule was marked by the emergence of several modern nation-states. The process of decolonization was premised on a sovereign commitment to societal and economic development. The programmes of development were often conceived, debated, refined and revised during the period of anti-colonial struggle and found expression in projects and plans that were implemented after independence. Modernization through science and industrialization were the crucial ingredients of these projects. The priorities of science and scientific research

varied not only between nations within the same region, but also between regions. In addition, the importance accorded to science in each nation differed from that of its neighbours. India appeared to have reaped the benefits of a political establishment that favoured science during the first two decades of independent rule. In Sri Lanka, however, the relationship between the political elite and the scientific establishment was not marked by the same kind of trust. As a result, changes in the scientific and technological system initiated were at variance with the perceptions of the scientific community.

Intellectual decolonization was reflected in a change in historical perspective and emphasis, a change whose impact was still evident on the social sciences three decades later. Referring to a historiographic revolution in the last decades of the twentieth century, American social scientist Sandra Harding recently pointed out that post-colonial science studies had effected three important changes. Firstly, it helped give a new perspective on the integrity of European scientific disciplines. Secondly, it clarified the nature of the relationship between European and non-European cultures. In addition, these studies specified the nature of interaction between European and non-European sciences and went on to provide a different perspective on how modern science was reconstituted as a result of the encounter with the knowledge forms of the non-West. The articles comprising the present chapter reflect the spirit of this new perspective, as they were written by some of the scholars who have contributed to this change.

This chapter intends to demonstrate that while modern science, as a Western cultural import and with its markedly distinct institutions, was assimilated within the region, the process is interpreted differently today. The idea of the civilizing mission has been replaced by the notion that the so-called expansion of European sciences was catalysed by the combined efforts of imperial bureaucrats, their scientific entourage and indigenous traditions that viewed this encounter as a path to revitalization. Seen from a certain distance, the process could be perceived as a sort of 'trading

zone' in which so-called indigenous knowledge forms transacted with the practices of modern science, though frequently in the idiom of modern science. This dynamic relationship constantly reshaped modern science. Consequently, the growth of modern science and European colonial expansion were inextricably linked. This has naturally prompted a number of post-colonial critiques of both science and modernity. However, this is not the issue to be debated here. Nevertheless, these undercurrents are perceptible in some of the articles, just as others are marked by the optimism that science would be able to promote development if it were given the chance to do so. Consequently, the politics of science is more or less a backdrop for any discussion for science in the former colonies.

The process of decolonization was not a purely cultural endeavour. Rather, it involved the reconfiguration of the institutions of colonial science, dovetailed to serve the politico-economic policies and programmes of the new nation-states. This task was rarely conceived as the demolition of British legacies, but one of pragmatically assimilating elements that were suited to the post-colonial developmental agenda. In the South Asian region, however, the imperatives of hard-earned sovereignty and the pressures of maintaining economic self-reliance created pressure to leap-frog into the regime of international science. Any perceived interest in the scientific past in India was indeed subordinated to the more demanding pressures of the fast globalizing scientific research system.

The movements for independence from colonial rule had planned for the rapid creation of educational and scientific infrastructure after colonialism. The main actors in the political formations that spearheaded these movements were involved in the planning process and drawing up of programmes for the post-independence institutions of scientific, technological and industrial development. Since the scientific leadership were closely involved in the anti-colonial struggle, they acquired a great deal of latitude with the post-independence political leadership in negotiating and fashioning the destinies of the scientific and technological institutions of the independent nations. The political legitimacy conferred by the state on science, and vice versa,

*Map 19* **Decolonization and new states in East Asia (after 1945)**

facilitated the rapid building of scientific institutions. In the case of India and Pakistan, a number of strategic areas of scientific research were protected from bureaucratic and political intervention, which created the illusion that science was autonomous of the social institutions that gave it legitimacy. The dualist character of the economies of the region further reified this chimera of autonomy. The dualist economies of the South Asian region certainly prevented science from developing its full potential.

Consequently, by the last decades of the twentieth century, a number of factors – some strategic, others having to do with the pressures of catching up with the global sciences – skewed the research priorities of the South Asian region either towards strategically important science or market-driven science of the advanced capitalist world. The social agenda of science of the early half of the nineteenth century was thus replaced with that of a neo-liberal ideology. This may have catalysed the internationalization of science, but it also produced a disconnection between the scientific research system and internal social demand. This was not a purely regional phenomenon: UNESCO responded with a conference to discuss a new social contract for science.

During the period immediately after the demise of colonial rule, the commitment to economic self-reliance and the compulsions of national security generated policies oriented to building indigenous scientific and technological capabilities. The articles in the present chapter chronicle diverse aspects of this history. The cultural, educational, institutional and cognitive responses to modern science and industrialization, in the context of the struggle for liberation from colonial rule, constitute the substance of the articles. Consequently, a number of geo-political as well as internal economic crises in the 1960s and 1970s played a crucial role in re-orienting research priorities, such as the thrust towards the 'Green Revolution'. On the other hand, the amplification of strategic and defence considerations steered funding towards the scientific research system and established technological priorities that enabled a limited leap towards the frontiers of high-technology. Thus by the 1970s, a new contract was

worked out between civil society, strategic and defence interests and the world of science. In areas such as satellite research, a great deal of effort had to be devoted to *indigenization* since the international marketplace of science was closed to the import of technologies of strategic importance. Similarly, the Cold War compelled governments to invest in defence research. This resulted in sub-contracting research to scientific institutions that took advantage of this opportunity to build scientific and technological capabilities. The end of the Cold War has not yet prompted a conversion of defence research establishments to civilian research facilities.

At the dawn of the new millennium, we could ask how many dreams have been realized, and how many have gone awry. In terms of scientific institutions, there exist a number of regional disparities. As pointed out by one of the authors, India has the densest network of scientific institutions after China. But as is reflected repeatedly in several of the articles, the impact of science of the two regions is not as significant as is desired. This impact is measured in terms of citation figures and the quantum of research output in influential research journals. While a number of theoretical objections may be raised in opposition to scientometric analysis, the fact remains that these figures are indicators of the infrastructure of science in the region. Among the countries that set out on the path of development, India and Pakistan could claim achievements in certain areas of advanced science and technology such as space exploration, nuclear technology, telecommunications and information science, but the problems of poverty and hunger remain. The population explosion, environmental crises, and the range of ethical and moral crises engendered by the rapidly advancing biotechnologies will bring to the fore new issues that need to be addressed politically by 'knowledge-societies'. The negative effects of globalization appear to be accumulating in developing economies as the state withdraws from the areas of health and education and essential infrastructure. The manner in which this situation will shape regional research priorities and scientific institutions remains to be seen.

## WESTERN THOUGHT, EDUCATION AND SCIENCE IN INDIA

### *Aparna Basu*

### INTRODUCTION

The decision to introduce Western education in India, as a result of Macaulay's famous Minute and Lord Bentinck's Resolution, was a momentous step taken by the British Raj, and the year 1835 could be regarded as an important landmark in the history of modern India. Throughout the non-Western world in recent centuries, the process of modernization has been accelerated by contact and conflict with the West. The introduction of Western education was one of a series of acts which opened the doors of the West to the East. The impact of Western thought, though limited to the urban intelligentsia, was significant, as this class, though small in number, played a crucial role in shaping modern Indian history.

It was no part of the East India Company's policy during the first two generations of its rule in Bengal to impose a Western system of education. The Company was a trading corporation and its primary interest was in making a profit. The immediate reaction of its officers was to support the existing system of learning since they did not want to tamper in any way with indigenous institutions. But the Evangelicals, Liberals and Utilitarians soon questioned this early policy in England of encouraging Oriental education. While there were numerous differences between them, they were all agreed that Indian society had to be radically transformed and European education was one way of doing so.[1] The plan of supporting Oriental institutions was condemned by James Mill as 'originally and fundamentally erroneous'[2] because the aim of education was promotion of useful learning rather than 'obscure and worthless knowledge.'[3]

The earliest efforts to introduce any formal education beyond the indigenous knowledge came from the missionaries. Rich citizens of Calcutta, Bombay and Madras also came forward to set up English schools in collaboration with individual European officials and businessmen. In Calcutta, Ram Mohun Roy, together with David Hare and others, founded Hindu College in 1817, the first secular institution in Asia to give Western education in English. Almost a decade later the Elphinstone College was started in Bombay. The number of such schools and colleges started increasing, and British rule gradually supplanted the pre-colonial indigenous system of education, imposing a new language and curriculum.

The first three modern universities of Calcutta, Bombay and Madras were founded in 1857. Like London University, on which they were modelled, they were purely examining and affiliating bodies which undertook no teaching or research. The actual teaching was done in the colleges, but the university, which also conducted examinations, laid down the syllabus. Indian universities were meant to be instruments for strengthening British cultural and intellectual domination. European learning was the staple of the curriculum, and the fundamental aim was the diffusion of 'the improved arts, sciences, philosophy and literature of Europe.'[4] This was accomplished through the administrative structure, the curriculum, and the language of instruction. Initially, the Vice Chancellors as well as the Registrars and other high academic officials as well as Principals and staff of government colleges and of many private colleges were recruited in Britain, and there was close personal contact between the teachers and students. The influence of Derozio on his students in Hindu College in the 1830s[5] or of Professor Patton on students of Elphinstone College, Bombay, in the 1840s and 1850s is well known.[6] English influence on Indian higher education until the First World War was very pronounced. As Charles Wood conceived it, the Indian university had two main functions – to provide a test of eligibility for government employment and to transmit an alien culture.

Despite the alien character of the new system, there was an eager response to it, especially in the metropolitan cities of Calcutta, Bombay and Madras, and later in Lahore, Allahabad, Agra and in other cities where there were greater opportunities for Indians to find jobs in the government or in professions like law, teaching or journalism. Young men also took to it because it opened up new ideas and visions; as Gopal Krishna Gokhale said, it liberated the Indian mind from 'the thraldom of old world ideas.'[7]

From 1911 onwards, there was a growing disillusionment with the model of affiliating universities. The first university to deviate from the affiliating model was Benares Hindu University (BHU) set up in 1916, the same year as Mysore University, which was the first university to be established

in a princely state. BHU was a unitary, teaching and residential university. In 1917, the Calcutta University Commission was appointed under the chairmanship of Sir Michael Sadler. One of its major recommendations was the setting up of unitary, residential and teaching universities. If the first three universities were modelled on London, the Oxbridge model inspired Sadler and his colleagues. Of the universities set up between 1917 and 1929 at Aligarh (1920), Lucknow (1921), Dacca (1921, now in Bangladesh), Delhi (1922), Nagpur (1923), Andhra (1923), Agra (1927), and Annamalai (1929), only Nagpur, Andhra and Agra were unaffiliated. The rest were all teaching and residential. Apart from Osmania University in Hyderabad, the medium of instruction everywhere was English. The Depression of 1929 put an end to the opening of new universities. Between then and independence only one university was founded in the princely state of Travancore and three universities were set up in British India – Utkal (1943), Saugar (1946) and Rajasthan (1947).

## SCIENCE AND TECHNOLOGY UNTIL MID-CENTURY

Since the primary function of colleges and universities was conceived of as diffusion of Western culture it was natural that priority was given to the study of English language and literature. The Indian component in the curriculum increased after 1921 but Western learning still continued to be emphasized. Not only was the curriculum Western in orientation, but it also tended to ignore scientific and technical education. The Hindu College had been established in order to cultivate 'European literature and science' and the original curriculum was 'comprised of not only reading, but also instruction in history, geography, astronomy, chemistry and other sciences'.[8] Ram Mohun Roy in his famous letter to Lord Amherst in 1824 pleaded for the instruction of European sciences.[9] The Native School Book Society, founded in Calcutta in 1817, prepared textbooks in Bengali on geography, astronomy and natural sciences. A similar society was formed in Bombay. It was through the publications of these societies that Indians first became acquainted with Western science. The British introduced modern science and technology as a substitute for and in opposition to the traditional system of Sanskrit and Arabo-Persian learning.

Although Wood's Despatch of 1854 made specific references to the spread of Western science, and the Indian Education Commission of 1882 and the Calcutta University Commission in 1917 suggested the inclusion of natural sciences and vocational and technical subjects, these recommendations were not implemented. The bias was very much in favour of general or liberal education. Instead of training scientists, technologists or agronomists, Indian higher education was engaged in producing office clerks. In 1916–17, nearly 80 per cent of the total enrolment in Indian universities was in general education. Till then there were only four government-engineering colleges, which offered degree courses only in civil engineering, as civil engineers were needed for the construction and maintenance of roads, bridges, canals and buildings. Electrical engineering was first taught at the Indian Institute of Science in Bangalore. The first-degree classes in mechanical and electrical engineering were started by BHU in 1917. It was not until the 1930s that the Sibpur, Poona and Guindy engineering colleges introduced degree classes in mechanical and electrical engineering. Until 1947, the Dhanbad School of Mining (Bihar) was the only full-fledged school of mining and it accepted only ten students a year. BHU also provided a graduate course in mining. Until the First World War there were only four medical colleges. Higher posts in the engineering and medical services were reserved for Europeans and the availability of jobs for technically qualified Indians was extremely limited.

British policy towards science and technology in India until the Second World War is a story of improvisation. The main factors influencing the official attitude during these years were the economic interests of the Raj and the empire and their military and political requirements. Local needs and indigenous demands exerted their influence only occasionally. A few salaried scientists and technically qualified persons were employed in government scientific services for routine research on field sciences. While important results did emerge from these efforts, the facilities were restricted and hence there was very little scope for scientific research. While the policies and the involvement of the foreign government in scientific and technical education were, as could be expected, in furtherance of their own interests, some Indian intellectuals and people of vision, who were themselves the product of such an education, provided new leadership. The last quarter of the nineteenth century and early decades of this century witnessed personalities like Mahendralal Sircar, Asutosh Mookerjee, Jagadish Chandra Bose and P. C. Ray who were instrumental in heralding Western science, teaching and research into India. Sircar, a graduate of Calcutta Medical College, realized that to develop a capability for original scientific work, research has to be institutionalized, research scholars have to be remunerated, well-equipped laboratory and library facilities provided, high-level lectures and discussions instituted, and facilities for communication among research workers provided through conventions, seminars and publication of journals.[10]

The technical and scientific education that was introduced by the government was meant mainly to meet its needs and requirements. Curzon and his successors wanted to spend money and effort on technical and industrial schools, not on higher scientific or technical education. The Indian intelligentsia was not interested in industrial schools that would teach weaving, carpentry or leather crafts. They wanted more polytechnics and engineering colleges. Rao Bahadur R. N. Mudholkar introduced a Resolution in the Imperial Legislative Council in 1910 for the establishment of a Polytechnic Institute. Mohammad Ali Jinnah, later Pakistan's first Governor General, supported him, among others. But such proposals coming from Indians were always dismissed by officials as vague and impractical or showing lack of appreciation of the difficulties of the problem. Curzon rejected them as 'native clamouring for things about which they know nothing.' And the Viceroy of India, Lord Minto, was assured by officials that 'such harmless platitudes' deserved no serious considerations.[11] Jamshedji Tata's scheme of setting up an institute for scientific research took almost thirteen years to bear fruit.[12]

Since the 1880s, educated Indians had been pressing for more government expenditure on technical and scientific education. The Indian National Congress at its annual sessions always passed a resolution stressing the imperative

need for technical and scientific education, as did newspapers with a nationalist bias. The leaders of the swadeshi movement in Bengal started a college of engineering and technology at Jadavpur in 1907, which is at present one of the important centres of technical education in India. While other national schools and colleges collapsed ignominiously, this technical college survived, which was itself a proof of the demand for technical education.[13]

Curzon's much-maligned Indian Universities Act of 1904 permitted Indian universities to undertake postgraduate teaching by appointing 'university professors and lecturers, to hold and manage educational endowments, to erect, equip and maintain university libraries, laboratories and museums ... which tend to the promotion of study and research.' Sir Asutosh Mookerjee (1864–1924), a mathematician of high attainments and then Vice Chancellor of Calcutta University, seized on this one section of the Act as the wand with which to convert Calcutta University into a teaching and research institution.[14] The Government of India was not willing to give any money for the establishment of academic Chairs or for laboratories, as it regarded Calcutta University as highly political and anti-British. But thanks to the provision in the Act for the acceptance and management of educational endowments and the princely endowments of Taraknath Palit, a lawyer and nationalist, and Rashbehari Ghosh, an eminent jurist and scholar, Sir Asutosh was able to establish the University College of Science and Technology.[15] These and other endowments that followed soon enabled the appointment of full-time professors and research scholars. According to the terms of the endowments, the positions of professors were to be filled by Indians and the principal duties of the incumbents would be to carry on original research with a view to extending the bounds of knowledge, to stimulate and guide research by advanced students and to arrange for the instruction of students preparing for B.Sc., M.Sc. and D.Sc. degrees. Research and training in science thus began in Calcutta University despite the Government of India's reluctance to assist it. Acharya Prafulla Chandra Ray, who was already a distinguished teacher at Presidency College and internationally renowned for his work in isolating mercurous nitrate, was the first Palit Professor of Chemistry, and C.V. Raman (later a Nobel laureate), the first Palit Professor in Physics, was appointed in 1917. Ganesh Prasad was the first Professor of Applied Mathematics and S. P. Agarkar was the occupant of the Ghosh Chair of Botany. Jnanendra Chandra Ghosh, Meghnad Saha, Satyendra Nath Bose, Sisir Kumar Mitra were some of the distinguished scientists associated with the University College of Science. Sir Asutosh tried to get the best scientists from all over the country and wanted to make the College of Science an all India college 'to which students would flock from every corner of the Indian Empire, attracted by the excellence of the instruction imparted and the facilities provided for research.'

There was considerable interaction between the University College of Science and the Science Association. The University had the endowed chair but no physical laboratory at that time, while the Association's case was just the opposite. The two complemented each other. The scholars appointed from the endowed funds who were interested in working under the guidance of Raman found an excellent laboratory in the Association. The combination of a full-time research guide, research scholars, well-equipped laboratories and libraries stocked with the latest publications soon produced good results in physics, chemistry and other branches of science.

The First World War exposed India's industrial backwardness and her dependence on others for a variety of commodities, such as machines and industrial equipment, and technical and scientific skill. As the country was an important source of manpower and munitions, the governments both in Britain and India recognized that it must become more self-reliant scientifically and industrially. An Industrial Commission was appointed in 1916 to examine steps that might be taken to lessen India's scientific and industrial dependence on Britain. The Commission – presided over by Sir Thomas Holland and including some leading Indians such as Jamshedji Tata, Rajendranath Mukherji and Pandit Madan Mohan Malaviya – proposed that 'In the future the Government must play an active part in the industrial development of the country' and this would not be possible unless there was 'reliable scientific and technical advice.' The Commission identified the absence and misdirection of technical and industrial education as one of the significant causes for India's industrial under-development. It recommended a comprehensive scheme of technical education and a closer relationship between scientific workers, government departments, universities, scientific institutions and industries, and between industrial education and local industries. It recommended the creation of a specialized imperial scientific service to be manned by Indians and wanted government to encourage the formation of scientific societies. The scope of the recommendations was broad, covering many aspects of industrial development, including the establishment of mechanisms to expand scientific education.[16] But few of the Commission's recommendations were actually implemented. Most of the subjects involving science and technology, like education, industry, agriculture, health, etc., were transferred to provincial control under the Montagu Chelmsford Reforms of 1919. Mahatma Gandhi's opposition to Western technology and large-scale industrialization lessened somewhat the nationalist pressure on the government for starting new industries and for higher scientific and technical education.

The commercial needs of the British led them to think about Indian agriculture in scientific terms. A beginning had been made in agricultural education by the establishment in 1905 of an Imperial Agriculture Research Institute at Pusa in Bihar. In 1916, two conferences were organized by the Government of India, one at Pusa and another at Simla, to discuss the question of agricultural improvement. But under the 1919 Reforms agriculture became a 'transferred' subject, i.e. in charge of the provinces. Nevertheless, the Indian Central Cotton Committee appointed in 1921 and the Imperial Institute of Animal Husbandry and Dairying in 1923 gave a new orientation to crop research and animal sciences respectively. The Cotton Committee, set up to promote the production and exploitation of cotton, established a technical laboratory at Bombay (1924–25) and an experimental station in Bikaner (1930). A Royal Commission of Agriculture was appointed in 1926 under the chairmanship of Lord Linlithgow to examine and report on the condition of agriculture and the rural economy of India with particular reference to the measures being taken for promotion of agricultural research and veterinary research. As a result of the recommendations of the

Commission, the Imperial Council of Agriculture Research was established in 1929 with the object of guiding, and co-ordinating agricultural research and education. Central Commodity Committees dealing with research in particular crops were set up, such as cotton (1921), jute (1936), sugarcane (1944), tobacco (1945), coconut (1945) and oilseeds (1947). These were semi-autonomous bodies financed by grants from the Government of India or by income from cesses levied under specific Acts. Agricultural research was compartmentalized into particular crops and institutions without co-ordination at any stage.

Little attention was paid to agricultural education. In 1921/1922, there were six agricultural colleges with 445 pupils. By 1947/1948, there were 29 agricultural colleges with about 5,000 students. The agricultural courses had, however, little relevance to the practical needs of Indian agriculture. There were hardly any institutes for teaching dairy or poultry farming, horticulture or veterinary science.

Botanical research was stimulated by the establishment of teaching and research departments in the universities from the 1920s onwards. Indian botanists such as B. Sahani (Lucknow), P. Maheshwari (Delhi), M. O. P. Iyenger (Madras) and others made significant contributions in their fields of research. The introduction of degree courses in zoology in several Indian universities in the 1920s helped in imparting training in the subject. The establishment of the Zoological Survey of India in 1916 led to the development of animal studies. A bacteriology laboratory established in 1889 in Pune was transferred to Mukteshwar in 1893 and a branch was opened in Izatnagar, Bareilly, in 1913 known as the Imperial Veterinary Institute.

In 1934, the Industrial Intelligence and Research Bureau was started, with its administrative wing in Simla and the research wing at the Alipur Test House in Calcutta. Its object was to make a 'beginning and to lay the foundation on which a research organization suitable for the needs of the country could later be constructed.' An Industrial Research Council was set up by the government to advise on measures for the co-ordination and development of industrial research. The outbreak of the Second World War made officials in London and New Delhi once again realize the importance of harnessing the potential of modern science and technology for the war. The decade preceding independence, with the intervention of the war, saw science, scientific organizations and training applied to meet specific needs. During this period there were some 20 universities, 500 arts and science colleges and 140 colleges of professional and technical education. Eight universities offered postgraduate courses in different branches of science, and 38 engineering institutions imparted training to nearly 3,000 students annually. The total number of scientific societies was around 60. The annual average turnout of postgraduate science students was 900, and of engineering graduates over 1,000. By 1947 there were nine Indian Fellows of the Royal Society of London and one Nobel Laureate. In order to develop the technical know-how and skill of the Indians, technical courses were encouraged and efforts made to organize technical education. For this purpose, an Association of Principals of Technical Institutes was formed in 1941, which was followed in 1945 by the constitution of an All India Council of Technical Education. A Scientific Terminology Committee presented its report in the same year. A Scientific Advisory Committee was created under the Department of Health. Similar boards and research committees were formed in the provinces and princely states. Official and non-official conferences and symposia were organized to discuss the country's needs, such as post-war organization of scientific and industrial research.

Western education in colonial India remained concentrated in and around cities where English medium schools and colleges were established. Though English education was in theory available to all, its spread was extremely uneven. Some regions were more advanced than others. There were differences even within a region between one district or group and another. Everywhere it was more advanced among men than women, in cities than in villages and among the higher castes. It would have been almost impossible to find a scheduled caste girl studying in an English medium school or college before 1947. Thus there were serious inequities in the colonial system of education.

The study of English brought about an intellectual revolution. The organization of the democratic state, its secular character, the structure of its institutions, and the principles underlying them, are all largely European in inspiration. Similarly the social reforms in Hindu society, the movements for the emancipation of women and for the removal of untouchability reflect Western influence to a considerable extent. The English educated intelligentsia imbibed new ideas such as liberty of thought and expression, responsible and objective criticism, tolerance of different opinions, government by discussion and the importance of the individual. But these ideas did not filter down to the masses. Traditional Indian society was hierarchical, and higher education in pre-colonial India had been largely the privilege of the upper castes and classes. These very groups took to Western education initially, which led to a widening of the gulf between them and the masses.

The negative alienating effects of English education are fairly obvious. The education system, by building up an educational elite and neglecting popular education, helped to preserve and strengthen the barrier between the upper classes and the masses. The use of English raised the class/caste barrier even higher. The low rate of literacy, the method of teaching, contempt for manual work, emphasis on literary education and neglect of technical and scientific education – all these constituted formidable obstacles in the path of development. The precise pattern of 'learning from the West' depended on the degree of political independence. In Japan modernizing efforts were first made in the army, administration and economic life. It is tempting to speculate what kind of Western learning India would have borrowed had she had the freedom to choose.

## POST INDEPENDENCE – THE NEHRU ERA, 1947–1964

Independent India inherited a system of education that had been established under colonial rule. It was not only quantitatively small but also qualitatively unsuited to the task of building a self-reliant and growth-oriented economy and a forward-looking society. The need for a literate workforce was regarded as essential in this context, to provide an adequate pool of highly skilled employees. Emphasis was placed not only on rapid expansion of primary education but also on simultaneously strengthening higher education as a whole and particularly technical and scientific education.

The Government of India consequently took various measures to promote scientific and technical education. The University Education Commission (1948–49) recommended that 'as a general part of education for living every step of education from primary school to the completion of undergraduate university work should include teaching of science.' The Secondary Education Commission (1953) suggested a 'General Science Course' for schools. The aim of this was not to produce scientists but to give a basic understanding and appreciation of scientific phenomena. In March 1958, Nehru moved in Parliament to pass the Scientific Policy Resolution. The aims of this policy were among others, 'to foster, promote and sustain, by all appropriate means, the cultivation of science and scientific research in all its aspects, pure, applied and educational; to ensure an adequate supply, within the country, of research scientists of the highest quality … to secure for the people of the country all the benefits that can accrue from the acquisition and application of scientific knowledge.' Soon after Nehru became Prime Minister, he created a ministry of scientific research and natural resources.

Since independence, higher education has expanded enormously. In 1947, India had 20 universities. By 1964/1965 there were 62. During the same period, the number of engineering and medical colleges as well as of polytechnics also increased substantially. By the end of 1965/1966, admission to technical education reached nearly 24,000 for degree and 50,000 for diploma courses. A six- to eight-fold increase in a period of 15 years was quite remarkable. But it was difficult to find employment for these large numbers of graduate engineers and diploma technicians. As a result, after the 1970s, enrolment in science courses started declining. Sadly, there was also a very low enrolment in the veterinary and agricultural colleges. The Council of Scientific and Industrial Research (CSIR) established a chain of national laboratories in a wide variety of fields – chemistry, physics, glass and ceramics, aeronautics, etc. It also set up six regional laboratories. The Indian Council of Agricultural Research was the premier body for sponsoring and co-ordinating agricultural research, as was the Indian Council of Medical Research for medicine. The Tata Institute of Fundamental Research, Mumbai, and the Indian Institute of Science, Bangalore, were the leading institutions for scientific research.

The All India Council of Technical Education, set up in 1945 on the advice of the Central Board of Secondary Education, had recommended the establishment of a number of Higher Institutes of Technology. The first of the Indian Institutes of Technology (IIT) was set up in Kharagpur in West Bengal (1951), followed by Bombay (1957), Madras (1959), Kanpur (1960) and Delhi (1961). They concentrated on postgraduate teaching and research. The IITs soon gained great international prestige and many of their brightest graduates went abroad for research and found employment in foreign universities or research institutes. The establishment of the IITs and National Laboratories drew away talent from the universities, where scientific research started to decline.

In the Five Year Plans, programmes for the development of technical and scientific education were emphasized. In the Second Plan a provision of Rs. 500 million was made for this as against Rs. 230 million in the First Plan. New engineering colleges and polytechnics were established, including many in the private sector, a new phenomenon.

Several of the new national and regional laboratories and institutes were lavishly planned regarding buildings and sometimes equipment but often lacked high-calibre teachers or researchers. There were not enough diploma-level institutes. As a result, whereas India boasts of having the seventh-largest pool of technically trained people in the world, it does not have enough technically trained persons with low-level skills, and the high rate of illiteracy is a contributing factor.

During the process of drafting the Constitution, much time and energy were devoted to the language question. There was naturally a demand that English, associated as it was with foreign rule, could not be retained as the national language. At the same time, it was realized that Hindi was neither sufficiently developed nor sufficiently widespread to become the national language. Hence a compromise formula was evolved: all major Indian languages were given equal status as 'national languages'. Hindi was made the 'official language' for all India purposes; English was to continue as the 'official language' for 15 years from the time the Constitution took effect. The Official Language Commission was appointed in June 1955 to study the progress achieved so far and recommend a timetable for the changeover to Hindi in ten years' time. The Commission observed how, during British rule, English had gradually superseded the Indian languages in the work, activities and thought processes of the higher intelligentsia of all linguistic regions and in the course of time become the sole means of communication at the all India level, or the lingua franca of all persons holding positions of authority or prominence in public life. 'With a rich and well developed language like English at hand, the official language of governance, the medium of instruction for all advanced education and also the language of the learned professions, the Indian languages naturally failed to develop a sufficiently rich and precise vocabulary for the requirements of modern social life.' Despite all this, the Commission felt that English could not be the common language as only about 1 per cent of the population could speak it. The Parliamentary Committee, which examined the Official Language Commission Report, recommended that the changeover to Hindi should take place by 1965, but added that English might continue for any period and purpose laid down by Parliament.

The publication of the Official Language Commission Report in 1957 led to acute differences of opinion on the language question, particularly in the southern states of India, where educationists, people of letters and scientists demanded an explicit commitment that English would continue as the official language. Linguistic riots and popular protest in the southern states led Jawaharlal Nehru to make a formal pronouncement in Parliament in August 1959 that English would continue as an 'additional official language' as long as people required it and that there would be no imposition of Hindi on non-Hindi speaking people. Under the Official Language Act of 1963, English was adopted as an associate official language without any time limit.

Since Independence, the medium of instruction at the primary, secondary and tertiary level in a majority of institutions has changed over to the regional language or Hindi. This has naturally led to a fall in the standards of English. But the popularity and demand for English continues to grow, as the knowledge of the language is the door for admission to institutions of excellence and to

employment. All professional colleges and institutions of national importance such as the Indian Institutes of Technology, Indian Institutes of Management, All India Institutes of Medical Sciences, etc., continue to have English as the medium of instruction. Privately managed 'quality' institutions, usually located in cities, also teach in English, and pupils from such schools take away the lion's share of seats in the prestigious courses in engineering, medicine and management. English is the language used in day-to-day business in private firms, banks, insurance companies, and multinational corporations as well as in government offices.

Consequently, there are two classes of educated people in India – those educated in English and those educated through the medium of the mother tongue/regional language or Hindi. The former constitute a privileged class, which is closer to all decision-making positions, while the latter occupy a subordinate position. This dual system of education has perpetrated and consolidated the position of the English-educated elite. The major share of the world's knowledge, particularly scientific knowledge, is produced in the West, and English is the chief language for the communication and dissemination of this knowledge. Hence English still continues to dominate the life of the intelligentsia. In this sense, Indian education has not broken free of colonial bondage. Macaulay's influence continues. But instead of bemoaning this and crying for a radical restructuring of the education system, better to alter the content of courses and curricula at all levels, as already done to a large extent, and to make them more Indian- and Asian- oriented. Basic books have to be translated into Indian languages. Too much emphasis on Western thought and English language can retard self-reliant thought and work, too little of it may lead to intellectual isolation.

## SCIENTIFIC PRACTICES IN INDIA
## BEFORE INDEPENDENCE

*Kapil Raj*

Although the inhabitants of the Indian subcontinent have possessed distinctive scientific and technological traditions for over two millennia, they had little trouble in becoming part of the emerging institutions of international science and technology during the latter half of the nineteenth century. Indeed, Indians today represent the third-largest national community of researchers. Already in the early decades of the twentieth century, the productive Indian community of researchers counted among its members, apart from a Nobel Prize in physics, many distinguished fellows of the most prestigious international scientific and technological societies. In the present article we shall examine the evolution of traditional scientific practices in the wake of this massive shift from one context of production, validation and circulation of knowledge to another. However it would be instructive to preface our remarks with some observations on the nature of 'traditional' science in South Asia.

One of the most noteworthy aspects of traditional science in South Asia is the manner in which knowledge was hierarchically organized in the classical Hindu tradition: contemplative and other forms (e.g. linguistics, astronomy, mathematics and, later, astrology) concerning ritual practices being situated at the apex. These forms of knowledge, the preserve of higher castes, were held in greater esteem than practical know-how (e.g. pottery, carpentry, spinning, weaving, metallurgy, alchemy, irrigation technology, etc.) relating to material needs. Some of the 'higher' forms of knowledge – grammar, phonetics, etymology, metric and permutations and combinations in mathematics – arose within the Vedic schools as a necessary condition for mastering, communicating and expounding the Vedas (together with all of the most prestigious Brahminical works), laconically composed in strict metre in Sanskrit, a language conceived and meticulously developed for oral transmission. An erroneous recitation of the Vedas was considered not only a fault but also a catastrophe for the ritual in question. Other disciplines, such as astronomy and mathematics, have served to determine the time and location of rituals and other practical purposes. Writing, although it has existed in the Indian subcontinent for over two millennia, was considered to be a technical skill rather than a culture medium or learning tool.[1] Thus, there developed alongside

the aforementioned disciplines, a set of mnemotechnics through which priests could memorize the vast Vedic corpus by isolating words independently of their meaning and inverting the normal order of words, verses, and speech combinations; and each of these complex recitation techniques in this learning process is designated by a specific expression.[2] All these disciplines, linguistic as well as mathematical, and the accompanying mnemotechnics were elaborated in Sanskrit and traditionally considered to be appendices of the Vedas in order to ensure their preservation, transmission and continued use. This enormous corpus of knowledge was transmitted through rigorous formal instruction that lasted at least twelve years.[3]

Practical *savoir-faire* was also generally transmitted orally but in local, vernacular tongues within each of the (lower) caste groups, most often within the family unit or sometimes through the centralized professional guilds. Meaning literally 'the language of the cultivated', Sanskrit was the closely guarded prerogative of the Brahmin castes.[4] This, of course, is not to say that a standardized intellectual language imposed uniform knowledge and practices. Quite to the contrary, intellectual practices were conceived of within the framework of a variety of philosophical and cosmological traditions that varied from region to region and over time: like other cultural practices, those related to knowledge were not fixed. They varied according to the religious and philosophical leanings of the patrons – princely courts, powerful families – or to the specificities of the groups of practitioners.

The establishment of Islam as a major religious and cultural force in South Asia from the beginning of the second millennium added to the complexity of the institutional basis of scientific practice in the region, not least by disturbing the relationship between orality and writing. Indeed, by the mid-eighteenth century written media were being used in complex and creative ways to complement and reinforce oral culture in both Hindu and Islamic communities. In addition, Islam brought with it a series of knowledge practices in fields as varied as mathematics, astronomy, geography, map-making, surveying, instrument-making and medicine. These fields of expertise interacted, in many cases, with those of the

subcontinent, giving rise to hybrid forms of specialized practice, for instance the Hindus' use of the astrolabe for astronomical computations within the framework of Hindu astronomy and astrology. However, in areas untouched or less affected by Islam, knowledge practices followed other evolutionary patterns, changing for example because of endogenous pressures. Keeping in mind the immensity of the subcontinent and the diversity of histories of its regions, what can be called 'traditional' knowledge in India, far from being static in nature, thus covered many different sorts of specialized practices each within a specific historical context.

The advent of British rule introduced yet other changes to scientific and technical practices in the subcontinent. The fundamental unity, claimed by Sir William Jones and other officials of the East India Company in the late eighteenth century, between classical Sanskrit, Latin and Greek and the cultures in which they circulated, has been widely acclaimed as the beginning of scientific linguistics and comparative philology. This 'Orientalist' movement in British intellectual history had a considerable, albeit unintended, consequence: Hindu elites acquired a new sense of pride through a reinforced consciousness of their past.[5] Through the revival of Orientalism, this glorious Hindu past was equated with ancient Greece and Rome, the reputed cradle of European civilization and science. Orientalists held that classical Indian civilization had declined just like the civilizations of classical Greece and Rome.

With their reawakened self-awareness, the Hindu elites thus began wilfully to reinstate their long lost past by revitalizing the methods of contemporary European science. Thus, in 1817 they established the Hindu College in Calcutta (later to become today's Presidency College) without any assistance from the government in order to cultivate English literature and European science. And when the British opened the Sanskrit College in Calcutta in 1824 to teach Bengali children Sanskrit, rhetoric, sacred literature, law and grammar, the Hindu elites pleaded for the instruction of European sciences, forcing the school to introduce into its curriculum mechanics, hydrostatics, optics, astronomy, mathematics, anatomy and medicine – all in English. The resulting programme was a fusion of traditional Sanskritic studies of rhetoric, sacred literature, law and grammar with Western literature and science. Almost half of its students opted to study these disciplines, even though they were not required subjects.[6] Meanwhile, the Calcutta School Book Society edited mathematics and science manuals based on traditional pedagogy.[7] This hybridizing trend was to continue throughout the nineteenth century and was indeed institutionalized through the establishment of the first three universities at Calcutta, Bombay and Madras in 1857. Following close on their heels, came the *Calcutta Journal of Medicine* (1868) and the Indian Association for the Cultivation of Science (1876), both founded by a Calcutta-educated physician, Dr. Mahendralal Sircar. At the turn of the century, the University College of Science, also at Calcutta, with Chairs reserved for Indian scientists in, among other subjects, physics and chemistry, was founded by Sir Asutosh Mookerjee, amateur mathematician, High Court judge, active member of the Asiatic Society of Bengal and later Vice-Chancellor of the University of Calcutta. Soon after their creation, these universities and institutions were to

achieve distinction in world-class science by fostering pioneers like Jagadis Chunder Bose, Prafulla Chandra Ray, Chandrasekhara Venkata Raman, Satyendranath Bose, Megnad Saha and Homi Jehangir Bhabha, to name but a few. Although many Indians got assimilated into the mainstream of international scientific and technological practice, an appreciable number also sought to revalorize traditional Indian scientific learning and practices. Their approaches to problems and their expression of solutions are clearly structured by this hybrid tradition. Mahendralal Sircar, for instance, held that European medical theory and practice were not in any *a priori* sense superior to traditional Indian medicine. Thus, although the decline of princely courts under British colonial rule also meant the disappearance of the sponsoring and certifying institutions of traditional science in the Subcontinent and thus of traditional science, the simultaneous valorization of both traditional Indian and European cultures by many of their founders and later members meant that these new institutions playing such an important role in the development of modern science in India were also the ones which fostered a traditionalist discourse on science: the very same institutions served both to introduce Western science and to reinvent and legitimate traditional science in a sense similar to that developed by Hobsbawm and Ranger.[8] In this way, traditional learning entered a progressive phase – at least that part of traditional learning that sought to incorporate Western intellectual practices and skills within the overall framework of a renewed Hinduism. On the other hand, the production of traditional science that took place outside this new institutional framework, which doubtless continues to this day, was rendered unidentifiable owing to the decline of traditional institutions that guaranteed its certification and publicity.

This idea of a merger of indigenous 'paradigmatic traditions' and Western cognitive and material practices finds concrete expression in the praxis of these scientists who, while being able to communicate perfectly with their Western peers and colleagues, used traditional cosmologies and skills of the subcontinent as resources both in problem choice and in ways of going about their problem-solving.[9] In the remainder of this section, we shall try and illustrate this phenomenon through an account of the lives and works of two distinguished Indian scientists and Fellows of the Royal Society: Jagadis Chunder Bose and Srinivasa Ramanujan.

Jagadis Chunder Bose, the son of a deputy magistrate, entrepreneur and amateur physicist, biologist and engineer, was born in 1858 in what is now Bangladesh. His family, of Kayastha origin, had converted to Brahmaism although his mother continued to adhere to the dominant Shakti cult.[10] After an initial education at a village school, Jagadis Chunder studied Sanskrit, Latin and physics with Father Eugène Lafont at St. Xavier's College, Calcutta. Upon graduation in 1879, he travelled to England with the intention of studying medicine, but with a scholarship and some encouragement by Lord Rayleigh, he transferred to Cambridge University and graduated in natural science in 1884. Bose returned to India and was immediately appointed professor of physics at Presidency College, Calcutta, where he remained until his retirement in 1915. A very able instrument maker, he gained international recognition early in his career through the generation, reception and optical properties of electromagnetic radiation in certain unexplored wavelengths. A few years later, Jagadis Chunder anticipated

Marconi's commercially exploitable wireless-transmission experiments by demonstrating for the first time the feasibility of the wireless transmission of electromagnetic signals in Calcutta and at the Royal Institution in London. He also gained recognition by elaborating a general theory of the properties of contact-sensitive substances in the field of what has now come to be known as solid-state physics. In recognition of his work the University of London awarded him a D.Sc. in 1896. However, from around 1900, Bose's religious and philosophical beliefs led him to study the similarities between the absorptive responses of inorganic and biological matter to centimetre-wavelength radiation and to various stimuli, a study that occupied him until his death in 1937. He published at least ten books on the subject.[11] 'Life takes form,' he wrote, 'due to the power struggle between the inner and the outer. At the source of both the outer and the inner lies the same *Mahashakti* who powers the nonliving and the living, and the atom and the universe.'[12] It is not surprising that this aspect of his work was not accepted by his peers and colleagues: 'In 1901 and 1904', writes Charles Süsskind, 'his papers were rejected by the Royal Society, partly because of the philosophical terms in which they were couched.'[13] Society members continued, however, to admire the extremely sensitive automatic recorders he devised to measure plant growth. He was knighted in 1917 and elected a fellow of the Royal Society in 1920. There is no doubt that Bose was conscious of the example he was setting as a leader in the resurgence of Indian – particularly Bengali – culture. For, on retirement from Presidency College in 1915, he founded the Bose Institute in order to 'further investigat[e] … the many and ever opening problems of the nascent science which includes both Life and Non-life.'[14]

Srinivasa Ramanujan was born in Erode in Madras State (present-day Tamil Nadu) in 1887 in a Vaishnavite Brahmin family.[15] He was brought up in Kumbakonam, where his father eked out a meagre existence as a bookkeeper to a cloth merchant. However, the family's poverty did not stop them from educating the young Ramanujan. At home, he was brought up within an orthodox Tamilian Vaishnavite tradition, a staunch devotee of Vishnu's consort and principal goddess of Kumbakonam, Lakshmi Namagiri. His mother, an adept of astrology, numerology and traditional board games, transmitted her paramathematical sensitivities to her son, who also developed an interest in the sayings of saints, the *Puranas* and other Sanskrit classics, all of which he frequently recited in traditional Brahminical style. By the age of ten Ramanujan had passed his primary school examinations in English, Tamil, arithmetic and geography, standing first in the district. At high school in Kumbakonam, he was already fascinated with the notion of zero, challenging his teachers, whom he had surpassed in mathematical knowledge, and was soon helping his fellow students in mathematics. But his real enthusiasm for mathematics arose in 1903, just before he left high school, when some college students staying with Ramanujan's family gave him a mathematics cram book to prepare students for the notoriously difficult Cambridge Tripos – the first volume of G. S. Carr's *Synopsis of Elementary Results in Pure and Applied Mathematics*.[16] As the title suggests, this was not a mathematics textbook but rather a progressive compilation of some five thousand equations, theorems, formulae, and geometric diagrams, all arranged by topic. Apart from the thrill of discovering the relationship between concepts and equations that the book suggested, Ramanujan also found its style particularly seductive, which corresponded to that of classical Sanskrit texts – a highly condensed sentence, or *Shruti*, sometimes accompanied by a commentary or *Bhasya*, but never a proof. From then on, and at the expense of his academic and professional career, he was to style his mathematics on this book, filling out two notebooks with a host of new theorems and commentaries in pure mathematics, inspired in part by what he read in Carr, but never a proof in the sense accepted by the contemporary mathematics community. Indeed, although in the years ahead Ramanujan found a number of sympathetic ears among professional mathematicians in India, no one was capable of evaluating his work because of its non-conformity. It was left to Godfrey Harold Hardy, a well-known but eccentric Cambridge pure mathematician to whom Ramanujan had been asked to write when all other peer evaluation had failed, to risk a positive judgement of his work and to invite him to spend some years in Cambridge. A unique collaboration and entente developed between the two men during the four years that Ramanujan spent with Hardy at Cambridge. During this period, Hardy put some of what he judged as Ramanujan's most important theorems into a language and conventions understandable by the modern mathematical community thereby rendering him one of this century's most prodigious mathematicians. Although Ramanujan died in 1920 of tuberculosis, which he had most probably contracted during his stay in England, his notebooks are still a source of inspiration for researchers in fields as distant as particle physics, metallurgy, crystallography, telecommunications and cancer research. And, because of their strange unconventional character, they continue to be one of this century's major enigmas.

The foregoing discussion shows the complexity involved in posing apparently simple questions concerning the spread of modern science, questions which take for granted that the successful introduction of scientific ideas or practices necessarily involves the renunciation of older knowledge practices or at least their relegation to the sphere of the traditional. Indeed, in concert with the Kuhnian theory of paradigm displacement, it is commonly believed that in the face of competing sets of practices, there is one clear winner and one clear loser. And if older knowledge practices do continue to exist, they can in theory be located within a clearly distinguishable group different from that of the practitioners of modern science. Further, if the latter group continues to believe in older knowledge forms, then this clearly shows a shortcoming in their practice. In contrast to 'pure' strands of 'metropolitan' scientific practice, scientific practice in India (and one might say in the non-Western world) can only be 'hybrid', tainted with past practices and replete with compromises with local knowledge traditions. And while they might accord a certain status to their practitioners within their own societies, they are certainly peripheral to international science.

Contrary to this perspective, I have tried here to show that older practices can be, and are, fruitfully incorporated into contemporary scientific practice. Moreover, the practitioners of this 'hybrid' science, far from being relegated to an insignificant periphery, are considered to be very much part of the scientific centre. Beyond pointing to the habitual and often artificial cleavages that historians seek to draw between a dynamic Western intellectual tradition, of which modern science is considered the spearhead, and static

forms of knowledge practised elsewhere in the world, it is hoped that this essay goes some way in blurring the boundaries between tradition and modernity as much as between centre and periphery.

7.    A remarkable example is that of an arithmetic textbook – Reverend May's *Gonito* – which was an attempt to give to the Indians their own arithmetic in printed form. It was noticed and accepted, strangely enough for rationalists of today, that the Indians had a system of arithmetic of their own. Speaking about these years in his evidence before the House of Lords, Horace Hayman Wilson, Boden Professor of Sanskrit at Oxford and erstwhile functionary of the East India Company in India, expressed this quite clearly when, in answer to a question about the use of the 'head' by Indians in calculating, he told his interrogators that they did indeed 'Very much; in fact their process is objectionable on that account; although they [the Indians] write down the different operations on a slate, they rub out the process, and give nothing but the results.…They have a process; but if you tell them to show you how they come to the conclusion, there is nothing but the conclusion to be seen; they have rubbed out everything but the result, and you have nothing before you to show their mode of going to work.' [Evidence of H. H. Wilson before the Select Committee of the House of Lords, 5 July 1853, in The *Second Report from the Select Committee of the House of Lords Appointed to inquire into the Operation of the Act 3 & 4 Will. 4, c. 85, for the better Government of Her Majesty's INDIAN TERRITORIES; … Minutes of Evidence, Session 1852–3*, London, 1853, p. 261]. It is reported that Reverend May's *Gonito* was largely preferred to another widely available work published by the Society – Harle's *Arithmetic* – which was based upon the 'European' model. Indeed, so popular was the book that the first edition of 500 was exhausted in a few months and the Secretary of the School Book Society regretted that so few had been printed, for 'even if 5,000 copies had been printed, the whole would have found ready outlets of distribution, [*Second Report of the Calcutta School Book Society*, Calcutta, 1821, Appendix X. Quoted in N. L. Basak, 'Origin and Role of the Calcutta School Book Society in Promoting the Cause of Education in India, especially Vernacular Education in Bengal (1817–1835)', *Bengal: Past and Present*, Vol. LXXVIII, January, 1959, pp. 30–69. ## COLONIALISM, NATIONALISM AND
## THE INSTITUTIONALIZATION OF SCIENCE IN INDIA

*Dhruv Raina* and *Syed Irfan Habib*

## MODELS OF TRANSMISSION

A comprehensive appreciation of the institutionalization of modern science in late nineteenth and early twentieth century India, then under British rule, requires that we recognize the diversity of theories concerning transmission of knowledge. The most significant one is that of the centre-periphery,[1] inspired in part by its analogue in economic theory, though there are radical points of departure. While the model presumes that science is a cultural universal, a problematic outcome of this assumption is that the process of the reception of science at the periphery, despite the social character of science, does not attenuate the practices of the science or the core values it possesses at the centre from where it diffuses.[2]

This theory serves as the point of departure for the present account of the institutionalization of science in India. This could be instantiated through the collegial ties, collaboration and apprenticeship of some of India's leading scientists, who spearheaded the process of institutionalization in India, with their counterparts in Europe.

Biography is a genre at the periphery in the history of science, for it shares a great deal with its counterpart in the West, for in both cases leading scientists and the processes they initiate or the theories they invent are framed within a myth of origin, from where the history of science then blossoms. In the peculiar case of the Indian scientist at the periphery of science in the late nineteenth century, the absence or underdevelopment of collegiality and institutional structures at the periphery draws biographers into portraying these scientists as exiles astride two worlds. As nowhere men, since women were few and far between at the time, the scientist at the periphery is portrayed as constrained by the lack of vision of his countrymen, and as an exotic specimen by colonial administrators. Such origin myths confer on the enterprise a sagacious beginning and in the process legitimate the identity of science.[3] To further our understanding of the process of the institutionalization of science in India during this period, we draw upon three intersecting frames. First, there is the larger process of the globalization of the sciences.[4] This in turn relates to the struggle of Indian scientists to gain entry into the world of science, and the constraints and opportunities offered by British rule in providing access to the invisible colleges of science at the centre. The final frame relates to the nationalist struggle and the impetus it provided to the institutionalization of science in India, in that specific context.

Towards the end of the nineteenth century and the first decades of the twentieth, India was at the periphery of modern science and aspiring to catch up rapidly with the centres in Germany, England and France. In this variegated cognitive, political and epistemological field, political and cultural considerations often moderated the acceptance of scientific claims made by the practitioners of science at the periphery. At the epistemological level, experience showed that scientific claims emanating from the periphery were most likely to be recognized once the scientists from the periphery gained entry into the invisible colleges that operated at the centre. While collegial ties and exchanges could be forged across social and geographic distances, successive encounters between a number of scientists also reveal much about the ways that the global political framework shaped their ability to participate in science.[5]

## THE FORCES SHAPING THE INSTITUTIONALIZATION OF SCIENCE

Modern science in India dates back to the age of exploration, first through the efforts of European missionaries and travellers, and later through trained scientists and bureaucrats employed by the East India Company to survey the colonies both for mineral and plant resources, as well as the topography of this vast subcontinent.[6] It coincided with the consolidation of the field around European centres. With the onset of the process of colonization this exploratory impulse led to the first institutionalization of science in India. The period from 1761 to 1903 was known as the Age of the Great Surveys, for the Empire's boundaries and resources were mapped during this time. Societies like the Geological Survey of India and the Trigonometric Survey were founded by the British to extend their dominion over

the country, as has been scrupulously detailed in Edney's carefully documented work.[7] There exists a great divergence and diversity of interpretation over the expropriative nature of colonialism itself, and whether or not this truly set the stage for the institutionalization of modern science in India. But generally, the colonial institutes founded by the British were seen as the primary conduits for disseminating modern science and scientific research throughout the subcontinent. There is unanimity among historians that the institutionalization initiated by the British endowed their rule with the symbols of imperial power, and the tools to manage, exploit and control their empire.

The absence of sovereignty in decision-making differentiates the Indian case from nations like China and Japan on the one hand, and settler societies such as Australia and Canada on the other. By the end of the nineteenth century Victorian India was endowed with a few 'teaching universities' and a low form of scientific and technical education administered under controlled conditions. Fundamental research was not included in the charter of the universities during this period, nor was it on the agenda of other imperial research institutes save for astronomy.[8] Until 1890 whatever research there was was undertaken largely through government departments or was monitored by them, and in turn complemented by the field surveys undertaken by the societies and/or military organizations. Without committing the error of an earlier generation of historians of science, who construed these surveys as a lower order scientific activity that in turn validated the centre-periphery model, We would emphasize that the surveyors often wore many hats and played a significant role in stabilizing the image and practice of Baconian science. What remains true of the older picture is that economic considerations weighed heavily in colonial decisions about the priority areas of scientific research. This prompted S. N. Sen, the historian of science, to ask why scientific progress in India came so late in the nineteenth century, despite the incredibly rapid expansion of European science and imperialism. Sen argues that the Imperial government accorded priority to such 'field sciences' as geology, botany, astronomy and cartography, which directly served the colonial agenda.[9] However, it must not be forgotten that the colony was a laboratory for a great scientific experiment that played a significant role in the colonial capitalist state. The colonial state was innovative in founding formal technical institutions that were replicated in England, thereby nourishing the technical development of education in England.[10] In a very important way, then, the colony provided the prototype for the subsequent framing of the state-supported science model in Great Britain.

The second stage in the institutionalization of science in modern India followed three-quarters of a century after the founding of the Asiatic Society in 1784, when the universities were established, first in the Presidency towns of Calcutta, Bombay and Madras in 1857, when followed by Punjab University, Lahore, now in Pakistan, in 1882, and Allahabad University in 1887. By 1900, there were 170 colleges, 4 colleges of medicine, 4 colleges of engineering, 28 medical schools, and 12 engineering schools. This major pedagogic endeavour should not be seen as a sign of the institutionalization of science, but the universities were producing knowledge and providing the battleground where the subsequent destiny of the scientific research system in India was fought. In the background the example of the

German university had inspired many a European nation and the United States. However, the universities in the Presidency towns developed in 1857 as teaching institutes and examining bodies. The intent was to produce Indians, true to Macaulayan diktat, in skin and colour but educated in English on the Western model, in order to train efficient government clerks to help run the empire. Postgraduate teaching and research was not part of the charter of these universities. It took fifty years of struggle by the Bhadralok community in Calcutta for the University Charter Act of 1904 to be enacted, permitting Indian universities to proceed with postgraduate teaching and research.[11]

This effort was preceded by the founding of the Indian Association for the Cultivation of Sciences, in Calcutta in 1876, and inspired by the British Association for the Advancement of Sciences. The IACS as it came to be called was a society supported by the native gentry, whose goal was to organize a modern scientific research system under 'native management' and directed on national lines. The first years were dedicated to organizing lectures in the sciences, popularizing science and gradually supporting small scientific research projects. The laboratories of the IACS provided institutional space for the early efforts of many of India's important scientists. On the other hand, the Indian Institute of Science, Bangalore, was not created through the efforts of a highly educated professional middle class, seeking funding for their efforts from the rural gentry (land-owning class) of Bengal, but emerged as an idea of a leading Indian industrialist, Jamsetji N. Tata. Tata, like his compatriots in Bengal, was dissatisfied with state of India's teaching universities (a euphemism for examining bodies), and proposed setting up a real university that he referred to as the Research Institute of Science and was later christened the Indian Institute of Science. The institute was founded through an endowment of his own, support from the Princely state of Mysore, and after years of struggle, with matching support from the Government of India in 1905. Tata had been instrumental in setting up India's first modern textile and steel mills, and was evidently inspired by the Humboldtian model of the university, which combined teaching and research. The institute he conceived would give a 'fresh impulse to learning, to research, to criticism, which will inspire reverence and impart strength and *self-reliance* to future generations of our and your countrymen.'

In addition to the German model, this industrialist was equally attracted by Johns Hopkins University, Baltimore. The historian of science Subbarayappa suggests two possible reasons as to why. The first had to do with its being the first university in the United States founded as a postgraduate institution, which is what Tata's institute turned out to be, a tradition continued today by the Indian Institute of Science.[12] P. C. Ray, the founder of the school of modern chemistry in India, disagreed with Tata's proposal on the ground that an institute where only mature scientists carried out their research would be out of place in India at the end of the nineteenth century. The Indian student still needed to be apprenticed to a researcher at an existing university. These universities needed to be well endowed and widened in scope. Ray's proposal was to build up capabilities from below whereas Tata was suggesting leap-frogging and proceeding with the task of building the new nation.[13] This is not to say that Tata's conception was purely instrumental. On the contrary it was a liberal one. However, as was the case with the National Council of Education in Bengal, the general consensus was

that the scientific and technical subjects should receive priority, with medical investigations next, and philosophical and educational subjects last on the list. In any case the industrialization of scientific research programmes was underway in the minds of those shaping the future of India's scientific institutions. The mood of the nationalist uprising was such that these efforts in university pedagogy were driven by the urgency of acquiring economic sovereignty.

## THE INSTITUTIONALIZATION OF PHYSICS RESEARCH

The institutionalization of the scientific research system that had commenced in the 1870s proved particularly fruitful for the future of modern physics in India. The period between 1890 and 1935 was punctuated by the notable contributions of J. C. Bose, C. V. Raman, M. N. Saha and S. N. Bose. An examination of the bibliometric data indicates that these four physicists dominated the field with their publications and that schools, traditions and networks of physicists grew up around them.[14] Bibliometric data further suggests the emergence of a community of physicists in India as well as the institutionalization of research. In particular, it could be emphasized that the decades between 1910 and 1930 were landmark years. In the nineteenth century, geophysics and geomagnetism were major research areas, undertaken at what is now called the India Institute of Geomagnetism at Colaba in Bombay. Sub-disciplines that included heat and thermodynamics, magnetism and electromagnetism, optics and radiation were also important, and marked by the extraordinary research efforts of individuals such as J. C. Bose, whose paper 'On the polarisation of electromagnetic waves by double refraction' appeared in 1894. The dispute between Marconi and Bose over the discovery of radio waves is now seen by some scholars in another light.[15] Bose may be credited with the production of short wavelength radio waves, in addition to which he was able to put forward a general theory of the properties of contact-sensitive materials. The institutionalization of physics research is further substantiated by the exponential increase in publications between the decades 1900 and 1920. Between 1910 and 1920 the number of publications doubled, and this pattern was sustained until the onset of the Second World War.[16] This quantum leap in the number of publications was reflected across all disciplines, but especially those which had been institutionalized for a hundred years. Consequently, by the 1920s the critical mass of researchers and the output of the group suggested that a school of physics had been instituted in Calcutta. Its members were situated at the Presidency College, Calcutta, and Raman, while a Professor of physics at Calcutta University, continued performing experiments at the Indian Association for the Cultivation of Science. In 1917 Raman transformed the proceedings of the Association for the Cultivation of Sciences into the *Indian Journal of Physics*. The next decade was to prove very fruitful. Raman's path-breaking work on molecular scattering had begun by 1925, Megh Nad Saha had written his most influential papers, which were instrumental in establishing the field of theoretical astrophysics, and Satyendra Nath Bose was to co-author with Einstein one of the papers that closed the quantum theory phase of quantum physics. In a manner of

speaking the community of Indian physicists were now part of the globalized community of physicists, and the gap between centre and periphery was partially bridged. Furthermore, many ideas originating at the periphery were to nourish the evolution of science at the centre itself.[17]

The most noteworthy feature during this period was the decreasing time needed for research produced in the metropolises of science to spread throughout India. During the last few decades of the nineteenth century this lag was about twenty years; by the 1930s it was less than five years. Hence, by the early decades of the twentieth century, the formation of research networks, and the institutionalization of physics research closed the temporal distance separating metropolis from province.[18]

By the time the first generation of Indian physicists had registered their presence in the discipline, two revolutionary developments heralded the golden age of contemporary theoretical physics: the special and general theories of relativity and the quantum revolution. Despite the contributions of Indian physicists, the university system did not create a post for theoretical physics until 1950. Most theoretical physicists functioned within departments of mathematics and applied mathematics, or in physics departments. The absence of political sovereignty constrained the choices available, and the peers of the scientific community had already forged ties, sometimes explicitly, with the nationalist struggle. Even within the Princely State of Mysore, C. V. Raman, by then a Nobel laureate, was unable to negotiate the appointment of Max Born, who was planning to leave Germany, to the department of physics at the Indian Institute of Science. This rebuff was one of many factors responsible for his quitting the Indian Institute of Science two years before he was to retire. He went on to set up the Raman Research Institute using the several awards he had received and additional support he had solicited.[19] The Indian Association for the Cultivation of Science had relatively greater autonomy. But even there no official positions were obtained until 1950. The Indian physicists working in general relativity and cosmology – such as J.V. Narlikar and P. C. Vaidya – carried out their research in departments of mathematics and applied mathematics. Within five years of India achieving independence, Homi Bhabha had established both the Tata Institute of Fundamental Research and the Atomic Energy Establishment Trombay[20] (later BARC); the contingencies of nuclear physics-related research prompted enormous growth in theoretical physics and mathematics.

The history of disciplines such as theoretical physics in India instantiates the case for the emergence of a non-field discipline outside the imperial rubric of science and in turn throws up problems for models of the transmission of modern science such as Basalla's three stage model. In fact, delving into the probable causes of the slow institutionalization of the discipline reveals the environment within which science was introduced in a colonized culture. The barriers to the dissemination of theoretical physics through this 'national', counter-imperial initiative may be identified at a number of levels. In the first instance, there was a paucity of infrastructure and institutions within which the discipline could take root. Consequently, leading theoretical physicists were pre-occupied at the height of their careers with the need to establish institutions for physics research. In cultural terms, the modernizing strain within the nationalist struggle imputed Indian underdevelopment to the disjunction

between theory and practice. During the discipline's formative years in India, namely 1910–35, it is likely that members of this network were not prepared to re-institute what they perceived to be a division of labour within science that could in turn prove detrimental to the performance of scientific research.[21] Thirdly, we must not preclude the importance of individuals and their persona in providing role models for subsequent generations of scientists. C. V. Raman's persona captivated the world of Indian physics. Raman was an experimentalist of outstanding merit, and inspired a whole generation of experimentalists after him.[22] However, his dispute with Born on Lattice Dynamics and subsequent souring of their relationship quite possibly soured his attitude towards all theoretical physicists.

Despite the globalization of science and the networking of Indian scientists with their colleagues in the international community, there remained the difficulties of pursuing science at the periphery. These difficulties were both institutional and a result of lack of opportunities produced by economic underdevelopment in the colonies. Thus, as DeVorkin argues, it was Saha's work that more or less created the discipline of theoretical astrophysics.[23] But this could not be translated into an opportunity for creating a centre that would lead the discipline. While the relative freedom in isolation liberated him from peer pressure and enabled him to tread entirely new pathways, his location at the periphery constrained him from exploiting the potential of his theory. Furthermore, he would have lacked the panoramic overview of the discipline that comes from being located at the centre.

## CONCLUSION

We began this discussion with the models of transmission in the history of science. This was followed by discussion on the forces shaping the institutionalization of science, first by colonialism, and subsequently by national resistance to colonial rule. Finally, we took up the specific case of the institutionalization of physics research in India to illustrate the issues raised. Against this local backdrop we pointed out the larger process of the globalization of science and the construction of an international community of science.

To recapitulate some of the points raised, we emphasized that the decades 1910 to 1930 were crucial for physics research in India on more than one count. The rapid rise in the number of publications during the decade 1910–20 was a spin-off from the University Charter Act of 1904 that empowered universities to undertake postgraduate teaching and research. During this early period, the bulk of research in these sub-disciplines was the product of the effort of a few gifted individuals, around whom schools gradually emerged. Their efforts were the most renowned contributions of a broader community coming to grips with the newly emerging front of knowledge. The older disciplines were highly dependent on the researches undertaken by a few individuals and their teams of researchers. The case was different with the newer disciplines, which benefited from the rapid diffusion of their work through universities and other research institutions.

The desire to inculcate new scientific practices like reporting and communicating research results found expression in the attempts by leading Indian scientists to switch publication to Indian journals in order to promote the development of physics research in India. They were partly influenced by emergent nationalist concerns, but this happened only after they had registered their presence in the international community of science. The first three decades of the twentieth century constitute a landmark in the institutionalization of physics research in India, wherein significant research and discoveries of front-running physicists was emblematic of a much broader process. Between the end of 1920 and the end of 1930 there was a 400 per cent increase in the number of scientific authors, and an almost 250 per cent increase between 1930 and 1940. A substantial community of physicists was beginning to appear, due to the forging of collegial ties, creation of networks and the institutionalization of physics research, as the distance separating metropolis from province was nearly closed.

## THE NATIONAL MOVEMENT IN INDIA AND THE FOUNDATIONS OF SCIENTIFIC AND INDUSTRIAL RESEARCH

*Dhruv Raina* and *Syed Irfan Habib*

### INTRODUCTION

As suggested earlier, the transmission of modern scientific knowledge to India through school and college curricula dates back to the early half of the nineteenth century. Pedagogically, there was a tension between two divergent strategies of instruction. On the one hand, there was the strategy proposed by the Orientalists, who suggested grafting modern science on to a Sanskrit base.[1] The Anglicists, on the other hand, proposed that instruction should proceed entirely on Western lines.[2] However, the debate was resolved by the installation of British rule in India following the uprising of 1857, and the Macaulayan Minute more or less dispelled any possibility of dialogue between modern or Western science and the traditional systems of learning. Ironically, Christian missionaries, with their larger evangelical agenda in mind, embarked on the path of promoting science, in the hope that this would stimulate the erosion of traditional knowledge forms and practices and thereby reinforce their own evangelical agenda. However, within three decades they were to realize that the 'native population' had taken to science without having abandoned their own religious beliefs or practices.[3]

In the Calcutta Presidency where these experiments were carried out in a very planned manner, a number of responses from the Bengali educated populace were manifest. The range of responses may be classed under three broad ones. The first was one of revivalism that rejected any form of dialogue with Western knowledge forms and proposed a retreat into the theological traditions of India. The second – at the other extreme – was that of Westernization, and, as suggested, it envisioned the emulation of Western knowledge and the Western model of development, and the consequent abandonment of traditional knowledge forms and practices. The third, called revitalist, argued for the critical assimilation of the developments in Western science and strategies of development, while simultaneously examining critically those elements of the Indian tradition that had not outlived their utility and possibly offered elements that could be salvaged and revitalized in the light of contemporary learning.[4] It shall be argued that attempts to build a national

scientific research system crystallized out of the last strain. In cultural terms, the devalorization of traditional knowledge forms – which was as much a product of the Eurocentrism of the times, as it was a weapon to legitimate colonial rule – prompted the first generation of Indian scientists to commence a historical examination of the sciences of India from the perspective of modern science. In this they were partially inspired by the endeavours of the British Orientalists who preceded them.[5]

Three decades after the Imperial Government had assumed direct control of matters of state pertaining to the Indian empire, the first signs of a nationalist uprising were becoming visible. The uprising was prompted by a number of misgivings and realizations about colonial rule. The new professions that had been created under the colonial regime did not allow the rising aspirations of a newly educated class to find gratification in the new regime.[6] In their continuous dialogue between the traditional knowledge systems and the advances made by the West in the previous centuries, Indian scientists reckoned two primary developments to be of crucial significance to their own situation. On the one hand, they were absolutely convinced of the need for the institutions of a scientific and technological research system on the German model. The installation of such a system would dovetail with the processes of technological and industrial development. But was the Western model of development and industrialization suited to the culture, resources and climate of the Indian nation?[7] This was a question that preoccupied the first generation of Bengali Bhadralok thinkers who were among the pioneers in institutionalizing the scientific research system in India. Convinced of the need for industrialization as the path to development, they were however sceptical of the Western model, and long debated the merits of finding alternative models of industrial development that were more suited to the industrial climate in the country. However, even within this group there were those who came from a background in the engineering sciences and technical disciplines who disagreed with these alternate conceptualizations and pressed for the implementation of rapid industrialization, albeit it under national control.[8]

Sir Mokshagundam Visvesvaraya, a leading engineer of his day and the most important figure spearheading the

industrialization of Princely Mysore, promoted the idea of industrialization with the caveat that India had much to learn from the experiences of Japan, Sweden and the United States.[9] These three nations had object lessons to offer because they were, until recently, lagging behind the industrialized West but had rapidly caught up in a few decades. Thus while the discourse was split between various adaptations of the Western model of industrialization on the one hand, and the demand for retailoring industrial development to work at lower economies of scale not involving mass or consumer-belt production, the unifying feature was that the attempt underway was to achieve economic self-reliance, and this could only be ensured if it was founded on adequate scientific and technological capabilities.[10] The burgeoning nationalist struggle thus refashioned the discourse on science, technology and industrial development to dovetail with an emerging portrait of social transformation, and presented itself as the cultural and political identity of the nationalist movement. This vision of social transformation had to serve a dual purpose, that of legitimating the processes of modernization while simultaneously containing the cultural erosion and devalorization of Indian culture that had been unleashed by colonial rule. This was one of the primary cultural tasks for the critical assimilationists within the nationalist movement.[11]

## EARLY ATTEMPTS AT INSTITUTIONALIZING SCIENTIFIC RESEARCH

Against this backdrop we briefly examine the emergence of some of the early attempts at institutionalizing the scientific research system outside the frame of institutions of science that were constructed as departments under the Imperial government. The emerging nationalist struggle gave concrete form to the scientific and technical institutions founded in the late nineteenth and early twentieth centuries. In 1876, an Indian doctor, Mahendra Lal Sircar, founded the Indian Association for the Cultivation of Science (IACS).[12] The Association was created in response to a pressing demand from educated Indians for the university to cease to be merely an examining body. Throughout the second half of the nineteenth century, Western-educated Bengalis were demanding of the British Government a full-fledged scientific research system. When the IACS was founded it sought to combine the character, scope and objectives of the Royal Institution of Great Britain, and the British Association for the Advancement of Science. Nevertheless, its objective, Sircar pointed out, was to 'carry on the work with our own efforts, unaided by the government … I want freedom for the institution. I want it to be solely native and purely national'. Within a decade the IACS had already become the fount of inspiration for a whole generation of Indian scientists entering the profession of science.[13] The Association that was set up through donations from the landed gentry of Bengal provided laboratory facilities for researchers seeking to pursue a scientific career but unable to find facilities for doing so at the university. As a scientific society it provided the institutional umbrella for popular and learned scientific lectures. By the turn of the nineteenth century it came to embody nationalist aspirations for scientific advancement. The Association blossomed in the wake of the emerging nationalist struggle in the country,

and the greater the reluctance displayed by the imperial administration to accede to the demands of the Association, the greater the resolve on the part of the incipient scientific community to ground their independent efforts.[14] However, it must be pointed out that, in a sense, two of the leading scientific lights at Calcutta at the time, the physicists J. C. Bose and P. C. Ray, reflected a Pasteurian internationalism.[15] By that we mean they were committed to the idea that the progress of science was dependent upon the functioning of an international community of scholars and the collaboration that joined them together. On the other hand, they also recognized that through the advancement of the sciences prestige and economic benefit accrued to the nation. Ray, possibly more than Bose, given his vocation as a practicing chemist, was more smitten by the vision of Berthelot's millennium.[16]

The evolving relationship between science and colonialism during the years of colonial rule is instantiated in the founding of institutions under the rubric of the national education movement and spearheaded by the National Council of Education. These are the Bengal National College – established through the efforts of the National Council of Education (NCE) – and the Bengal Technical Institute, Calcutta, established by a group that broke away from the NCE and started the Society for the Promotion of Technical Education (SPTE). Rather than internal faction fights within the same group, this divide embraced different visions of scientific and technical education – the former emphasizing the national and moral background of a humanist education and the latter pursuing the immediacy of developing technological skills.[17] These attempts were stimulated by a utilitarian vision of modern science and technology, a vision that had acquired currency among the Bengali Bhadralok class as well as other sections of the Western-educated Indian community. The undivided NCE included among its members the scientific and cultural constellation of modern Bengal. It was attempting to extend the research charter of the IACS into the domain of pedagogy: namely, that of founding an educational system on 'national lines' and under 'national control'. While eschewing the framework of Westernization propounded by the Macaulayans, it proposed instead critical assimilation from both the West and East. Through their cultural organ, *The Dawn*, the members of the Council sought to institute a critical examination of tradition and modernity.

In cultural terms the image of science among this educated elite was, to use a phrase from Thackray, that of a radical ratifier of a new world order.[18] Furthermore, science was also seen as the harbinger of economic prosperity and well-being. Within the relatively conservative Bhadralok class it could serve this purpose because science was ensconced within a moral economy that made it morally worthwhile and economically beneficial.[19] The partition of Bengal in 1905 stoked the fire of the nationalist movement and was a major blow to the sense of Bengali identity. The environment was surcharged in addition by the growing unemployment among the new intellectual proletariat that had been created but could no longer find jobs either in industry or government.[20] It was at this time that the NCE intervened by founding its own college whose educational agenda would be at variance with that of the Calcutta University, which was considered tainted since it was under British administration. Scientists such as P. C. Ray and J. C. Bose were clandestinely involved in the enterprise.[21]

The Council split in 1906 into the National Council of Education and the Society for the Promotion of Technical Education. The cause of dissension, as mentioned earlier, appears to have related to the pedagogy of scientific and technical education along 'national lines'. The scientists and engineers were quite sceptical about the humanist angle given to scientific and technical education and suggested that the moral and cultural or national component be dropped altogether; they emphasized the greater importance of developing deeper technical competence. Those from a humanities and liberal arts background went the other way. The two institutions born out of what was once the NCE continued to live separately for about five years. The immediacy of the nationalist struggle, given that both camps were committed to self-rule, and the growing demand for professional engineers and scientists to attend to India's mushrooming industry, resulted in a patch-up between the two camps.[22] The nationalist impulse was to be driven by the imperative of technological and industrial development – this was an element of the perceived contract between the state, on the one hand, and science and technology on the other.

In any case Ray, who in more ways than one carried the cultural authority of the sage-scientist, he was even called *acharya* had given credence to the idea that wealth flows out of the portals of the laboratory.[23] Ray was to write: 'The history of the modern supremacy of Germans in the industrial world is the history of triumphs achieved by succeeding generations of silent and patient workers in the laboratory.'[24] As a leading chemist employed by Calcutta University, Ray had established an industrial enterprise through public contributions, the Bengal Chemical and Pharmaceutical Works, whose products would replace the exorbitant imports from Europe. The new knowledge form and activity thus came to be coupled with aspirations for freedom from British rule. A prerequisite for self-rule (*swarajya*) was economic self-reliance (*swadeshi*).

The important feature of this episode in the history of the institutions of modern science in India is that, in characteristic late-nineteenth-century fashion, two ideas had acquired palpable currency: First, in contributing to science, prestige accrues to the nation; second, the path to political independence must be paved by economic self-sufficiency, which in turn requires an adequate scientific and technological base. Thus when Asutosh Mukherjee took over as the Vice-Chancellor of Calcutta University he set about operationalizing the provisions of the University Act of 1904 that made it possible to combine for the first time the functions of teaching and research. While informally associated with the NCE and their endeavours, Calcutta University provided a much larger teaching infrastructure and had a larger student population, and Mukherjee began revising programmes within the core. He believed that many of the changes demanded by the nationalist movement could be obtained within the framework of the existing universities.[25]

While the nationalist movement was in full swing, Asutosh Mukherjee proceeded to reform Calcutta University within the framework of the new act. It was at this time that Taraknath Palit, disheartened by his efforts to provide for technical education under the nationalist banner, handed over the assets of the Bengal Technical Institute to Calcutta University.[26] By October 1912, Mukherjee had received two donations, which enabled him to provide for two professorships in physics, two in chemistry, and one each in botany and applied mathematics

at Calcutta University. The Palit Professorships in chemistry and physics were the first two university chairs in science to be founded in India. One of the conditions imposed by the donors was that all chairs founded from their benefactions should be exclusively held by Indians.[27] By 1915, a substantial school of research in the areas of physics and chemistry had been established within Calcutta University through the research programmes initiated by J. C. Bose and P. C. Ray. C. V. Raman moved from IACS to occupy the first Palit Professorship Chair of physics at Calcutta University. The research agenda for the university stood legitimized.

Ray's nationalist impulse and belief that scientific research applied to the task of industrial development could render the nation economically self-reliant led him to establish Bengal Chemical and Pharmaceutical Works (BCPW) in Calcutta. He endorsed Mahendra Lal Sircar's belief that 'It is the chemist who must come to the rescue of threatened communities. It is through the laboratory that starvation may be eventually turned to plenty.'[28] As discussed earlier, within the NCE there were those who were dissatisfied with the model of large-scale industrial development and were considering other models of decentralized industrialization more in consonance with the resource base of the Indian rural economy.[29] By the late 1920s, Ray had lost confidence in the programme of large-scale industrialization being promoted by his own students at University College. Earlier, he had dismissed Gandhi's views on heavy industrialization but by the 1920s had become one of its most committed advocates. He recounted: 'When Mahatmaji [Gandhi] in 1921 first made the *Charkha* the symbol of the new movement, I myself, a staunch believer in mechanization, laughed at this relic of medievalism.'[30] However, it was during his involvement with a series of flood and relief operations in Bengal that Ray began to question his commitment to heavy industrialization through the application of science and found Gandhi's views more appealing.[31]

His views were not acceptable to his students, particularly Meghnad Saha, who by now was the leading Indian astrophysicist and was also actively involved in the emerging politics of the Indian National Congress. Saha was greatly influenced by the ongoing experiments in the Soviet Union. Saha's preoccupation with the frequent damage that floods unleashed in India led him to suggest the founding of a school of 'river physics'.[32] The Indian National Congress had advocated a programme of heavy industrialization almost immediately after its inception. This advocacy was muted only during the phase when Gandhi had assumed the leadership of the party, but although his emphasis on cottage and village industries had been incorporated within the party programme, those who held such views did not constitute the dominant faction. Jawaharlal Nehru articulated the worldview of the party in 1937 when he asserted: 'Congress represents science, and science is the spirit of the age and the dominating factor of the modern world. Even more than the present, the future belongs to science and to those who make friends with science and seek its help for the advance of humanity'. As with Saha, Nehru was deeply influenced by developments in the Soviet Union. The year he spent incarcerated in Naini Jail was devoted to reading the writings of Bernal and the other members of the Cambridge Left.[33] In 1938, a National Planning Committee (NPC) was convened with Nehru as its chairman, and several leading industrialists as well as

Meghnad Saha were members. The NPC produced a detailed report in 27 volumes, with a separate volume of views and recommendations on an integrated national plan. Seen in historical context, the NPC forged a common platform in politics, science, technology and industry for the country's leadership.[34] The action plan charted in these documents had much to say about economic independence and political freedom. But more importantly, it contained a kind of blueprint for the institutionalization of the scientific research system and industrialization that would follow after independence.

In 1934, Saha, together with a group of leading Indian scientists, had established the Indian Science News Association and an influential journal, *Science and Culture*. This association of scientists, which came to be known as the 'Science and Culture Group', advocated the utilization of scientific knowledge for heavy industrialization. Impressed by the results of planned industrialization in the Soviet Union, Saha and his group vigorously criticized the Gandhian programme in the pages of *Science and Culture*. But this was not the only ideological orientation that found voice within the national movement. Another vision was taking shape in the state of Mysore then under indirect British rule; and it was initiated by Visvesvaraya.[35]

As an engineer, Visvesvaraya's was a bootstrap vision of development that involved the simultaneous pursuit of three different strategies, or else the desired end results would not be realized. The primary effort had to do with the establishment of a scientific and technical education programme that would produce the necessary capabilities and skills to empower the programme of rural industrialization and the establishment of heavy industry. A plan for rural industrialization was drawn up that included increased acreage for irrigation and a blueprint for industrialization that would add value to the agricultural produce generated in the rural areas and plough it into the rural economy. And there was an ambitious plan for industrialization that would gradually reduce the nation's dependence on agriculture, as was the case in the developed economies. He was reasonably successful in ensuring the integration of these different strategies, since as a state under indirect colonial rule, there were greater degrees of freedom available and Mysore was considered one of the model states in indirectly administered India.[36] It must also be noted that Visvesvaraya published a book on planning, though his model was not the Soviet model but a state-capitalist one – in which the role of the state was to set up infrastructure that would provide the platform for private enterprise to take off. However, in his technocratic vision India's backwardness was ascribed to illiteracy and the consequent lack of skill and working capacity. Industrialization became an instrument of change and was reflected in his slogan: 'Industrialize or perish'. While considered the inaugurator of planning in India, reflected in his book of 1936 and by his association with the Bombay Plan, his approach should be distinguished from the Soviet-influenced approach of P. C. Mahalanobis.

## INDUSTRIAL RESEARCH

The industrial research system, considered as one of the founding pillars of industrial society and its history in India, is by and large the history of the Council of Scientific and Industrial Research (CSIR), the idea for which grew out of the deliberations of the National Planning Committee, the journal *Science and Culture*, and took final shape following the visit of Professor A. V. Hill, Biological Secretary of the Royal Society, to India in 1943. There is a substantial corpus of literature discussing the emergence of the CSIR and the institutions of industrial research founded by it.[37] The important feature to note is that S. S. Bhatnagar became the first head of the CSIR in independent India. It was through his proximity to Nehru that he was able to work towards the establishment of a network of twenty-two of the 'national laboratories' under the CSIR, between 1948 and 1958. The period between 1948 and 1964, within the discourse on planning, policy, or even for the purposes of political history, is alluded to as the Nehruvian era. The important issues of this era may be listed as follows: the path of socialist development was to be pursued; in the realm of international politics India had committed itself to non-alignment; the cultural goal of the age was a brand of scientific imperialism (the core of the new state would be organized around 'the temples of science', and further, the scientific temper was enshrined in the Indian Constitution).[38]

The image of Nehru as philosopher-statesman and Nehru as entrapped within the world of Realpolitik has proved to be the bugbear of most historians. What is certain is that his faith in science was close to religious faith and derived from his perception of the transformation of the world around him. As a historian of merit, whose *Glimpses of World History* and *Discovery of India* have their place on the bookshelf even today, he was able to visualize how the emergence of modern science and technology would profoundly alter the lives and outlook of people in the non-Western world. He sincerely believed that a critical commitment to science could drive the spirit of development of the new nation by igniting the spirit and minds of people: science was to be the principal instrument of rapid change. For Nehru, the human destiny was inextricably and inexorably linked with the progress of science. He once observed nostalgically: 'And though circumstances made me part company with science, my thoughts turned to it with longing. In later years, through devious processes, I arrived again at science, when I realized that science was not only a pleasant diversion and abstraction, but was of the very texture of life, without which our modern world would vanish away. Politics led me to economics, and this led me inevitably to science and the scientific approach to all our problems and to life itself'.[39]

In his view, the solution to India's problems lay in a combination of socialism and science, of technology and heavy industrialization. However, he was not just an uncritical optimist about science. Rather, he was well aware that the monster created by science had run amuck; and this rosy picture of science ushering in the golden age was tainted by the mushroom cloud of darkness that threatened the future of the human race.[40] However, neither he nor his generation of scientists felt compelled to put science in the dock, for variants of the use-abuse model continued to exonerate science, and the ideology of the Cold War reinforced this image of science.

By the early 1960s, a good decade after independence had been achieved, the efforts of scientists from the pre-independence era had proved fruitful, for India was able to proclaim that it had a reasonable scientific and technological research establishment and was rapidly joining the

international community of Big Science. In the last decades of the nineteenth century and the early decades of the twentieth century the attempt was to ground the research system within the university research system. By the time independence had been achieved, and driven by the need to catch up with the West, the imperatives of the new republic to deliver on the promises of development, the imperatives of national sovereignty and prestige – all drew the leadership of the scientific community, politicians and decision makers closer to the trajectory of mission-oriented research. Consequently, in the post-independence era, the industrial research and nuclear research imperatives provided structures for the subsequent institutionalization of science. What is certain is that institution-building on such a large scale, in a nation where resources were tight, was possible only because the scientific community was able to enlist the support of the political establishment for its plans. Furthermore, they managed to link their objectives with the larger development objectives of the independent republic.

## THE EVOLUTION OF SCIENCE AND TECHNOLOGY IN INDIA SINCE INDEPENDENCE

*Vissid Siddhartha*

India declared its independence from British colonial rule on 15 August 1947. As already discussed, several of those spearheading the freedom movement – the Indian National Congress – had already begun planning India's post-Independence institutions of industrial, scientific and technological development. The principal planner was Jawaharlal Nehru, the first Prime Minister of free India, whose ties with India's scientific community predated 1947. During the years of anti-colonial struggle Nehru often made public, through speeches and writing, not only his own ideas but also what other anti-colonial political formations expected from science for the development of India and the welfare of its people. But he did so much more frequently after Independence[1] when, as Prime Minister, he retained, *de jure*, ministerial charge in his Cabinet of the portfolio of Atomic Energy, and, *de facto*, of industrial science and technology.

Some of India's few scientists involved themselves in the freedom movement directly; but more did so through their affiliation with the Congress Party. In return, the Party allowed Nehru a great deal of latitude in fashioning the scientific and technological institutions of independent India in close consultation with scientists. Nehru conceived his task as one of building on the legacies left behind by the British.[2] He did not, unfortunately, examine closely the appropriateness of those legacies to fulfil the tasks that were later assigned to Indian scientific effort.

Until well into the 1950s the Indian scientific community remained small. It could only draw upon a university-based research tradition that was barely fifty years old. Its star, the winner of the 1930 Nobel Prize in Physics C. V. Raman, shunned government and its patronage, which lesser beings knew could not be done without.

And so Indian science gave a warm welcome to the state. The latter moved in gingerly in a self-effacing style that was in stark contrast to the unabashed machismo it displayed in the proclamation, in its Industrial Policy Resolution of 1956, of the intent of the state to occupy the 'commanding heights' of the industrial economy. In a statement in the Lok Sabha (Lower House of the bi-cameral Indian legislature) on 13 March 1958, Nehru tabled a copy of his government's Scientific Policy Resolution[3] and personally read it out, 'because we consider this Resolution as an important one, defining our attitude to science and technology generally.' This favourable attitude by the head of government in the highest political forum enabled India's young scientists, nascent as a community, to draw upon the resources of the state for programmes to be conceived and executed almost exclusively by them. Thus empowered, the community proceeded with the task of building fairly rapidly independent India's scientific institutions, into what is today the most extensive and dense of the scientific networks in the world's ex-colonies, save that of China.

The scientific community did not, however, quite get the point of the *quid pro quo* implied in the Scientific Policy Resolution, which was sought to be implemented 'by offering good conditions of service to scientists and according them an honoured position'. Consequently, the political cover and the needed protection that Nehru provided to the supply-side institutions of Indian science from the depredations of politicians and hostile bureaucrats also isolated the world of Indian science from its intended beneficiaries and customers. Scientists at leading centres and institutes worked in a 'hot-house' atmosphere, as they sought only to fulfil the targets of 'Plans' validated by a political system that was assumed to be conveying to the scientific community the needs of society through those 'Plans'. The 'hot house' also enabled the leading members of the community to gratify their need for recognition by their scientific peers abroad. What was scientifically fashionable was pursued, and this fashion was set in the West. While these practices enabled one type of international calibration of Indian science, they also resulted in a disconnection of the scientific research system from the Indian real world.[4]

Nehru had a special relationship with two of the major post-Independence scientific institution builders, Homi J. Bhabha and Shanti Swaroop Bhatnagar. Bhabha was a man with an aristocratic background and private financial means. His ancestors, who professed the Zoroastrian faith, had migrated from Iran and settled down in India centuries ago. Bhabha, who masterminded India's Atomic Energy programme,[5] was empowered, on his demand, with custom-designed administrative and financial enablements that were at refreshing variance with the disabilities hobbling the

other research establishment, headed by Bhatnagar, namely, the Council of Scientific and Industrial Research (CSIR) – a British legacy. Bhabha subsequently institutionalized a style of 'science governance' that has since become the norm for other post-independence 'high-technology' mission-oriented science and technology agencies in India, notably those overseeing the Space and Electronics programmes.[6] China, the giant neighbour to whom India lost territory in a war in 1962, conducted a nuclear weapons test in the atmosphere in October 1964. Two years later Homi Bhabha was killed in an air-crash in Switzerland. The departure of both Nehru and Bhabha, in quick succession, disrupted the rhythm of science governance in India. When Nehru's daughter Indira Gandhi became Prime Minister (after the death, not of her father in May 1964, but of Prime Minister Lal Bahadur Shastri) in 1965, India had already fought a stalemated war with Pakistan, which confirmed that India's industrial science and technology were not up to the task of supplying the military. Also, by the mid-1960s it became apparent that India's traditional agricultural system could not feed her rapidly growing population. Indeed, in 1966–67, India faced a food crisis, which raised the spectre of starvation and loss of national pride. India had to import food from those 'who had the means to give and did not give it without strings attached'. Scientists, politicians and influential commentators started asking: 'What is this science for; what is our technology meant to do?'

Those then were the contemporary historical circumstances in which Indira Gandhi asked for the convening in January 1970 of the historic Third National Conference of Scientists, Technologists and Educationists. From this conference's accepted recommendations there emerged the National Committee on Science and Technology (NCST) with a mandate to plan for the next phase of India's science and technology development. It did so, but now in a radically changed context of political-economy,[7] a change brought about in part by a five-fold increase, since the Scientific Policy Resolution of 1958, in the state's expenditure on scientific research and development,[8] and a four-fold increase in the number of personnel engaged in R&D and related activity.[9] Five Indian Institutes of Technology and a research-based medical university were fully functional, producing world-class technologists and medical specialists through English-language instruction – indeed, so world-class that the trickle brain drain to the First World (mainly the United States) that began in the mid-1960s presaged a future flood (which continues).

The war between Pakistan and India in 1971 saw the birth of the new nation of Bangladesh in South Asia. This war refocused India's attention and resources on strategic technologies, but now on those with 'dual-use', i.e. those which would be invested in primarily for development purposes, but which could also be used to military advantage.

In the fourth five-year plan, between 1969–70 and 1973–74, India's science and technology expenditure increased by a factor of five over the third plan, which ended in 1966. The Departments of Science and Technology and Electronics were created in 1971; the Department of Space was set up in 1972.

In 1974, Indira Gandhi authorized India's first underground nuclear explosive test in the desert of the Western border-state of Rajasthan, thus demonstrating a nuclear weapons capability. In 1980 India successfully launched, with its self-designed launch vehicle SLV-3, an artificial satellite that it also designed and made. She thus demonstrated the capability to build Intermediate Range Ballistic Missiles (IRBMs). Indira Gandhi continued this phase of institutional expansion of Indian science and technology on the 'supply-side' with the creation in the early 1980s of the government departments of Environment and of Ocean Development, with scientists in good standing in their fields hand-picked and appointed by her as their executive heads. ('My scientists', she would say to career bureaucrats, who got the message.)

In the mid-1970s, imported oil became almost unaffordable. The impact of this, and environmental problems caused by large hydroelectric projects[10] and coal-based power stations, compelled India to harness non-conventional energy sources. Indira Gandhi created the Department of Non-Conventional Energy Sources in 1982. By the mid-1990s India had the world's fourth-largest installed capacity of grid-connected electric power generated by the wind.

With nuclear weapons and IRBM capabilities clearly demonstrated, Indira Gandhi considered it now safe for India to begin to open up her economy. The almost religious adherence to near-autarchic self-reliance in the decades previous to 1980 was relaxed. Inevitably, as a corollary, Indira Gandhi's own stamp on the Nehruvian S&T model she inherited needed redesign. That redesign was incorporated in the formulation of a technology policy whose content she personally attended to. Indira Gandhi had to personally inform her special constituency – the scientific community – before effecting the impending change. She did so by releasing the 'Technology Policy Statement' at the Indian Science Congress in January 1983. But she was distracted by a terrorist insurgency in the border state of Punjab, and the administrative follow-through into implementation of that policy statement died with Indira Gandhi when she was assassinated in October 1984.

The Congress Party immediately anointed Indira Gandhi's son Rajiv Gandhi as head of the Congress Party. He won a General Election shortly thereafter and became Prime Minister of India. Rajiv Gandhi adopted a different style of executive functioning – a sort of Presidential style. Thus, while hitherto the top science and technology advisory bodies to the political government had been 'Advisory Committees to the Cabinet', Rajiv Gandhi appointed a 'Science Advisory Council to the Prime Minister'. This Council functioned from 1986 to 1990 as a compact body of a dozen members, none of whom were science-agency heads ('I want scientists, not bureaucrats'). Two of its members brought in from the private sector, and another US-based 'brain-drain' Indian telecommunication specialist, were personal friends of Rajiv Gandhi. Partly because of this unorthodox membership and also partly because this body went about its tasks in a way that alienated the Agency Heads – the science czars of the Indira Gandhi years – the latter did not consider the Council as legitimate ('Who *are* these guys?'). The Council, headed by an internationally honoured academic (the Director of the Indian Institute of Science in Bangalore) produced a two-volume report titled 'Perspectives in Science and Technology', which was later published.[11] In the meantime Rajiv Gandhi lost office in a General Election (he was later assassinated). The czars

respectfully placed the two volumes on the academic shelf, where they remain.

Following the collapse of the Soviet Union in the late 1980s, and its subsequent break-up, India realized that the relatively easy availability from that source of conventional munitions, combat aircraft and warships at 'friendship prices' was going to dry up. There was no alternative to providing for the requirements of the Indian armed forces from domestic military-oriented R&D. This activity therefore rapidly became the single-largest chunk of government-funded R&D, and has remained so ever since.

As Prime Minister, Rajiv Gandhi also explicitly authorized the application of India's nuclear capability to making weapons and authorized the test launch in May 1989 of India's Intermediate Range Ballistic Missile (IRBM), Agni-I. In May of 1998, Prime Minister Atal Bihari Vajpayee made good a pledge in the manifesto of the political alliance, which he led into power. Disregarding likely adverse international repercussions, he authorized a series of underground nuclear weapon tests, which were successfully conducted that month. In April 1999, Vajpayee approved the test-launch of the improved version (Agni-II) of India's IRBM, also successfully accomplished.

Thus, 50 years after the founding of the Indian Republic, the actually implemented post-Independence policies for the development of science and technology could, in retrospect, be viewed as having been largely driven by a continuing search for 'non-aligned' security, and to provide India with some insulation from the world's post-war neo-colonial structures of intertwined strategic, economic and technological power. A core element of India's science and technology effort this past half-century has been the attainment of self-sufficiency in food. India has also sought geo-technological parity by declaring herself a Nuclear-Weapons State, and by being one of five space-faring nations with an autonomous, economically and technologically competitive space-based communications and surveillance capability. These scientific and technological goals have been achieved at a remarkably low cost that has rarely exceeded 1 per cent of India's GNP in any year.

The modicum of self-reliance attained in non-security-related industrial development has been driven by public-investment from domestic saving, rather than technology provided through the pursuit of domestic R&D. This investment has carried with it technology embodied in imported capital goods, which is rarely leading edge, except when capital goods have been chosen by very bold (and therefore rare) domestic public-investment decisions not predicated by the terms of tied foreign-aid or loans from foreign banks.

This is not to say that there has been little contribution from domestic science and technology to India's industrial production. Indeed, an estimated 100 thousand million[12] Rupees worth of annual industrial production now results from the cumulative commercialization of industrial R&D conducted in Indian publicly and privately owned S&T facilities, many of which were set up with tax and other incentives introduced in the 1980s. Perhaps the most significant of the values added by domestic S&T to civilian industrial production, and exports, has been in drugs and pharmaceuticals. In 1970 Indira Gandhi got Parliament to completely change the law on patents left over from British times. The Indian Patents Act of 1970 abolished product patents on drugs. This measure has been responsible for

moving India from being an importer of medicines at prices her millions could barely afford, to being a seller to global corporations of licences to produce pharmaceuticals with technology developed in Indian laboratories.

And so, as we enter the new millennium having surveyed India's long history, her colonial burdens and legacies, and her post-Independence security anxieties and preoccupations, one asks: Could India's science and technology development this past half-century have taken a different path? It is, perhaps, too early to answer.

## THE DEVELOPMENT OF NATIONAL SCIENTIFIC AND INDUSTRIAL RESEARCH

# 36.6.1

## SCIENCE AND TECHNOLOGY IN PAKISTAN

*Faheem Hussain*

## INTRODUCTION

The development of science and technology in Pakistan since its independence in August 1947 represents some of the achievements and drawbacks of independent postcolonial governments that came into existence in the aftermath of the Second World War with the collapse of the great European colonial empires. It also represents all the drawbacks and meagre achievements of scientific and technological development driven from above without any organic links to society in general and to industry in particular. Although on paper there are many scientific research institutions in Pakistan, in reality the level of scientific research is extremely low.

Pakistan did not inherit any scientific institutions from the British Indian Empire and its educational base was extremely weak at the time of independence in 1947. At that time the University of Punjab was the only university in what is now Pakistan. However the University of Sind had been approved in 1946 and it opened in 1948. In addition there were three professional colleges, Maclagan College of Engineering and Technology, King Edward Medical College, Lahore, and the College of Agriculture, Lyallpur (now called Faisalabad).[1] Another drawback was that the two universities, following Macaulay's policies, were not conceived by the British as knowledge-producing institutions but merely as teaching institutions where students were taught to become good servants of the Raj. Thus Pakistan started its history without any tradition in scientific research. Everything had to be built from scratch. Like all newly independent countries Pakistan felt that it should also develop its own independent scientific and technological capabilities. There were a few individual scientists in Pakistan at that time who played a crucial role in the future development of education and science in the country.

Given the woeful lack of trained manpower, the initial effort was towards developing universities and educational institutions for the training of manpower in general and in science and technology in particular. An Education Commission was set up in 1958 and a Scientific Commission in 1959, and they duly made their recommendations. These recommendations were partly implemented and as a result the Agricultural College at Faisalabad was upgraded to the Agricultural University at Faisalabad, and the Engineering College in Lahore was upgraded to the University of Engineering and Technology. The number of universities has grown steadily since then and at present there are 26 public and 10 private universities. In addition there are four public and six private degree-awarding institutes.[2] Private universities have been allowed since the beginning of the 1980s when the first private university, the Aga Khan University, came into existence in 1983.

The creation of science and technology research institutions was taken up seriously in the 1950s. In the early years, before there was any significant local scientific base, these institutions were usually modelled on similar ones in the United Kingdom. Major government institutions like the Pakistan Council of Scientific and Industrial Research (PCSIR), Pakistan Atomic Energy Commission (PAEC), Pakistan Medical Research Council, Central Cotton Committee and the Food and Agricultural Council, later renamed the Pakistan Agricultural Research Council (PARC), were all established in the 1950s. Most of the progress Pakistan has made in science and technology originated during the tenure of President Ayub Khan, who made the first political commitment to science and education.[3] He gathered around him Pakistan's prominent scientists and appointed an active, young and brilliant theoretical physicist, Abdus Salam, as his Science Advisor in 1961. During this period (1962–69) not only was an infrastructure for science created but there was also a big effort for manpower development. The PAEC was revitalized with I. H. Usmani as its Chairman and Abdus Salam as its most active member. Usmani was a bureaucrat with a Ph.D. in physics who had a passion for science development. It was during this period that the Pakistan Space and Upper Atmospheric Research Commission (SUPARCO), the

Pakistan Institute for Nuclear Science and Technology (PINSTECH) with a 5 MW research reactor, the nuclear power plant near Karachi (KANUPP), Agricultural Research Centres at Faisalabad and Tando Jam and Nuclear Medicine and Radiotherapy Centres at major hospitals, the National Science Council, and the Defence Science and Technology Organization (DESTO) were created. The PAEC embarked on the programme of training more that 500 scientists in areas of experimental and theoretical physics, nuclear chemistry, health physics, engineering and agriculture. These men and women by and large constituted the country's major stock of trained manpower in the relevant disciplines. Subsequent Pakistani leaders continued their support for nuclear technology.

Another example of Ayub Khan's patronage is the Quaid-i-Azam University (QAU) in Islamabad. He had a vision of creating a postgraduate research-oriented university concentrating on research and graduate programmes in science and technology and the 'hard' social sciences. He saw to it that the university was developed properly and that it got international support and collaboration. He used his personal influence for obtaining two crucial grants for the university: a Ford Foundation grant, which was effectively used for short-term international contacts, and a UNDP grant, which was mainly used for the development of experimental facilities and for inviting long-term visitors. The results were encouraging, and, according to peer review, the Institute of Physics at the university was on the international map as an active centre of research in the highly competitive field of theoretical particle physics, in which it was possible to form a viable group in the very beginning. For the first time in the history of Pakistan, a graduate programme leading to the Ph.D. degree was started on a regular basis. The Ph.D.s produced were of top international standard. The above example brings out forcefully the importance of political commitment and patronage at the highest level for a scientific enterprise to flourish.[4]

## SCIENCE AND TECHNOLOGY RESEARCH DIVISION

A Science and Technology Research Division (STR Division) was created in 1964 to give special attention to the development of scientific and technological research facilities. The STR Division was placed under the administrative control of the President of Pakistan. The PCSIR, the PAEC and SUPARCO were all placed under the administrative control of this Division. In 1969 the STR Division was attached to the Ministry of Education, which was renamed the Ministry of Education and Scientific Research. However, except for the three organizations mentioned above, the sectoral research councils – the Pakistan Medical Research Council (1955), the Irrigation Research Council (1964) and the Council for Works and Housing Research (1964) – that were set up to promote activities in specific areas continued to function under the relevant sectoral ministries. Subsequently in 1972, to give special emphasis to science and technology in national development, a separate Ministry of Science and Technology was established, with the Scientific and Technological Research Division as its nucleus. With this reorganization, in addition to PCSIR, PAEC, and SUPARCO, some other research councils and scientific organizations, which were functioning under other ministries, were also transferred to the Ministry of Science and Technology. These were the Pakistan Council of Research in Water Resources, the Zoological Survey Department and Survey of Pakistan. Over the years there have been several reorganizations of the administrative structure of science and technology. Institutes in the fields of electronics, silicon technology, power and oceanography were set up as a consequence of the National Science and Technology Policy which was framed in 1984.

We have summarized the growth of research institutions in Figure 8, which shows the number of R&D organizations established per two-year period since independence. This figure[5] clearly illustrates the relatively rapid growth in the early years of the Ayub regime from 1959 to 1964 and the very large growth in the years of the populist regime of Zulfikar Ali Bhutto from 1971 to 1976.

*Figure 8* **Growth of R&D organizations**

*Source:* K. M. Khan, 1999, *Fifty Years of Science and Technology in Pakistan*, Pakistan Science Foundation, Islamabad.

The Ministry of Science and Technology is the focal agency in the Federal Government for S&T development. The organizations working under this ministry are listed below. Under a recent restructuring the Pakistan Council of Renewable Energy Technologies (PCRET) has been set up. This incorporates within itself the old Pakistan Council for Appropriate Technologies, the National Institute of Silicon Technology and the Solar Energy Research Council. The Pakistan Science Foundation (PSF) was set up in 1973 to support basic research in universities and research organizations on problems of national importance. It also manages the Pakistan Scientific and Technology Information Centre (PASTIC) and the Pakistan Museum of Natural History. The other major R&D organizations, mentioned earlier, are the Pakistan Agricultural Research Council (PARC), the Pakistan Atomic Energy Commission (PAEC) and the Pakistan Space and Upper Atmospheric Research Commission (SUPARCO). PARC is linked to the Ministry of Food and Agriculture, PAEC is directly under the charge of the Prime Minister, and SUPARCO functions under the administrative control of the Cabinet Division. The Kahuta Research Laboratories were established in 1976 as an essential part of Pakistan's nuclear programme. These were later renamed the A. Q. Khan Laboratories after the founder of the laboratory, Dr. A. Q. Khan, a metallurgist who was to play a very important role in the Pakistani atomic bomb project. In 1967 the PAEC set up a Reactor School at PINSTECH to train personnel in nuclear science and technology. In 1976 its name was

changed to the Centre for Nuclear Studies (CNS). This institute provided advanced courses in nuclear technology, nuclear engineering and nuclear medicine. These courses were recognized by the Quaid-i-Azam University for the award of the M.Sc. degree. Recently the charter of this institution has been widened and its name has been changed to the Pakistan Institute of Engineering and Applied Sciences (PIEAS).

The organizations under the Ministry of Science and Technology are as follows:

1. National Institute of Electronics
2. National Institute of Oceanography
3. Pakistan Council of Appropriate Technology
4. Pakistan Council for Science and Technology
5. Pakistan Science Foundation
6. Pakistan Council of Research in Water Resources
7. Pakistan Medical Research Council
8. Council for Works and Housing Research
9. Pakistan Council of Scientific and Industrial Research
10. National University of Science and Technology
11. Central Testing Laboratory.

The Ministry of Science and Technology does not administer all the R&D institutions; some are administered by the respective ministries, while the PAEC and its institutions are attached to the Prime Minister's Secretariat. In recognition of this problem the National Commission for Science and Technology (NCST) was established under the chairmanship of the Chief Executive of the country in 1988 for coordination of the S&T effort at the national level. However, it is very significant that this commission has met only once since its foundation – in 1989.

According to a recent study by the Pakistan Council for Science and Technology,[6] there are 151 major research and development organizations, including universities, in Pakistan. Given the large number of such establishments one would be tempted to think that science has progressed a good deal since independence. However this is very misleading. The tragedy of Pakistan, as of many other newly independent countries, was that its leaders were never seriously interested in developing science and education. They paid only lip service to the development of science. An analysis of recent budgets shows that Pakistan spends only 0.279 per cent of its GDP on science and technology. This includes both development and non-development expenditure. The allocation on development expenditure is even smaller, a mere 0.004 per cent of the GDP.[7] Funds are not available for books, journals and modern scientific equipment. The only exception to this is the generosity towards the PAEC and the A. Q. Khan Laboratory, due to their being engaged in Pakistan's nuclear programme.

## UNIVERSITIES

Although Pakistan has many universities, most of them continue on the colonial path as institutions that impart knowledge rather than modern universities where knowledge is created and where teaching is also carried out. Throughout the world universities are the sites where basic research is carried out but in Pakistan there is no tradition of research at universities. To overcome this, 'Centres of Excellence' were started in the 1970s. These centres were envisaged as research institutes within universities. The country now has on paper nine so-called Centres of Excellence, but none of them has been able to develop to international standard. Table 29 shows the growth of these Centres of Excellence. They lack quality staff, equipment and adequate libraries.

When taken together, all of Pakistan's universities spend only 2 per cent of their annual budget on research, although they possess the largest concentration of trained manpower, i.e. 65 per cent of the Ph.D.-level researchers in the country. However, only 25 per cent of the university teachers report research activity, even on a part-time basis. Calculated on a full-time basis this works out to only a few hundred researchers. Compare this with the figures for the UK

*Table 29* **Growth of centres of excellence**

| | Centre of excellence | University | City | Year established |
|---|---|---|---|---|
| 1 | Analytical Chemistry | University of Sindh | Jamshoro | 1974 |
| 2 | Mineralogy | University of Baluchistan | Quetta | 1974 |
| 3 | Geology | University of Peshawar | Peshawar | 1975 |
| 4 | Marine Biology | University of Karachi | Karachi | 1975 |
| 5 | Solid State Physics | University of Punjab | Lahore | 1976 |
| 6 | Water Resource Engineering | University of Engineering and Technology | Lahore | 1976 |
| 7 | Psychology | Quaid-i-Azam University | Islamabad | 1976 |
| 8 | Physical Chemistry | University of Peshawar | Peshawar | 1978 |
| 9 | Advanced Molecular Biology | University of Punjab | Lahore | 1983 |

*Source*: K. M. Khan, 1999, *Fifty Years of Science and Technology in Pakistan*, Pakistan Science Foundation, Islamabad.

(80,000 university researchers) and for Japan, (200,000). The number of Ph.D.s produced annually in the scientific and engineering disciplines is about 5, compared with 3,500 in India and 5,000 in the UK.[8] The one exception to this bleak panorama is the Quaid-i-Azam University (QAU) in Islamabad. In some departments, like physics and mathematics, QAU has continued to be fairly productive since its foundation. In fact as far as qualified physics staff is concerned QAU was and still is crucial to the development of the atomic energy programme and the burgeoning defence industry. Its physics graduates are highly prized in these sectors. Otherwise there are just a few individuals doing research in other universities.

## OTHER CENTRES OF RESEARCH

Let us now look at the state of the other organizations. Most of the existing 'research' organizations and research councils in Pakistan are so only in name. The actual scientific production in terms of research papers and patents is abysmally low. In the words of Qurashi and Kazi:

> Some of the research councils conduct basic research with the objective of utilising these for applied research and development, whereas some research councils dole out money for research to the universities and medical colleges. However, the major portion of their funding seems to produce results with no immediate applicability, only a venue for conduction M.Sc./M.Phil. Research and purchase of equipment, etc.[9]

This is a very severe indictment but it is borne out by the fact that some of the oldest research councils, the PCSIR and DESTO, have not produced anything of significance in their long years of existence.

According to the above-cited report of the Pakistan Council for Science and Technology, the total scientific and technological manpower in all organizations, including universities, is about 15,000 but this includes M.Sc. and M.Phil. degree holders. Out of this figure about 7,000 are scientists and engineers whereas the rest are technicians. This total figure in itself is extremely low for a country with a population of 140 million (just in terms of manpower, Turkey and Iran, not to mention India, overtook Pakistan in the years between 1962 and 1975; according to the UNDP *1999 Human Development Report*, Pakistan had 0.1 R&D scientists and technicians per 1,000 people compared to 0.3 for India, 0.7 for Iran and 0.3 for Turkey). The real tragedy shows up when one considers the total number of Ph.D.s engaged in research in these organizations, an incredibly low figure of just 1,932! According to K. M. Khan there are a total of about 2,500 Ph.D.s in science and technology in Pakistan.[10] Although about one half of them are in the natural sciences, these figures are extremely low, 110 in mathematics, 225 in physics, 388 in biology, 482 in chemistry. The largest number of Ph.D.s is in agriculture, 668, which reflects the importance of agriculture in the country's economy. However there are very few among them who actually do research of any significance. A recent study, by S. T. K. Naim of the Pakistan Council for Science and Technology and based on impact factors of scientific journals, shows that there are very few productive scientists in the country.[11] For example there is only one

physics department that has any impact at all, and that is the one at Quaid-i-Azam University, Islamabad. Similarly for chemistry the only one that counts is the HEJ Research Institute of Chemistry, Karachi University. Analysis of this survey shows that there are only about 90 scientists who have achieved Cumulative Impact Factors of 20 or above. In terms of scientific output Pakistan had dropped from second/third place to sixth, even in the Islamic world.[11]

Over the years governments have been aware of this lack of high-level manpower and have made sometimes rather half-hearted and misguided efforts to overcome this by instituting programmes to send people abroad for training. The one successful example of this is the training of experts abroad in the nuclear sciences (reactor physics, isotope production, nuclear safety), which was undertaken under the leadership of I. H. Usmani in the late 1950s and early 1960s. Now Pakistan is self-sufficient in training people in these fields. However other such projects have not been successful. The Government of Pakistan initiated the Central Overseas Training Scholarship Scheme in 1964 to train university and college teachers. This was augmented by scholarships offered by friendly countries. The effort suffered and still suffers from severe drawbacks. First of all, considering the magnitude of the problem, it offers a very small number of scholarships, at present (1997) 65 (43 for university teachers and 22 for colleges.[13] Secondly these scholarships have been open to misuse and have often not been given on merit but on recommendations and seniority. Thirdly many college teachers take up the profession as a last resort because they cannot do anything else. Finally university and college teachers who obtained these scholarships were not usually young people in their prime but were those who had been in service for some time and had gone through university and college many years ago. Many of them were interested in getting a higher degree not for the sake of learning but just to get more financial benefits and to enhance their careers. On returning home to Pakistan most of them did not do any more research. Even if some were sincere they could not pursue research in their home institutions because of unhelpful colleagues, lack of a research culture, lack of a research group of critical size, lack of library facilities and equipment. The government does have a limited number of merit scholarships, like the Quaid-i-Azam Scholarship, for students securing a first position in the master's degree, to study abroad for a Ph.D. However, once again, these are very few in number.

Realizing the grave nature of the problem, the Ministry of Science and Technology embarked upon the Human Resource Development (HRD) Programme in 1985. This was the largest R&D training programme ever launched by the government. It envisaged more than 1,600 overseas scholarships, over a period of ten years, for postgraduate studies leading towards the Ph.D. in the latest scientific and technological fields. In the first ten years of this programme about 1,100 scientists, doctors and engineers were sent abroad to pursue their studies, mostly in the USA and the UK.[14] According to Qurashi and Kazi,[15] 535 scholars had returned by June 1996 and were usefully employed, whereas Khan states that out of 1,000 scholars 800 had completed their studies by 1997 and that 200 were 'missing'.[16] This programme was discontinued in 1996 because of resource constraints. Although not very high the success rate was reasonable. The HRD scheme suffered from some

drawbacks, which need to be remedied, if such a scheme is to be revived. The selection process was not rigorous enough to select the best scholars. Some of the scholars selected were just not good enough to compete in the advanced countries and dropped out. Also the selection of the different subjects to be pursued was not done with sufficient care. Hence some of the scholars could not fit into the research environment here on their return because their field was not being pursued, and they either returned abroad or were unemployed. Finally a figure of 500 or 600 is a very small figure given the needs of the country.

Another indicator of the sad state of science in Pakistan are the figures on the number of science graduates, masters, and Ph.D.s produced in the country over the years. According to the study by Qureshi and Kazi, there was a steep initial rise from 1949 to the middle 1960s followed by saturation and even a small decline after 1974.[17] Their study goes up to the year 1980, but the general belief is that this stagnation has continued throughout the 1990s. The total number of M.Phil.s and Ph.D.s produced is extremely small. According to the same study, all the Ph.D. programmes together have been producing barely 10–20 science Ph.D.s annually, including agriculture. In contrast India produces about 900 Ph.D.s annually in the sciences. Pakistan has produced about 500 Ph.D.s in all the fifty years of its existence! One more indicator is the number of students enrolled in higher education as a percentage of the population in the age group 17–23 years. For Pakistan it is 2.6 per cent (1996) as compared to 6 per cent (1990) in India and well down from countries like the Philippines, Republic of Korea, Singapore, Hong Kong, Indonesia, Iran (Islamic Republic of) and Turkey, let alone the advanced industrialized countries.[19]

## CONCLUSION

After painting this dismal picture one is tempted to ask whether there is any science at all in Pakistan, given that it is an atomic power? The answer is yes and no. There are a few groups centred on individuals which do good research work. One obvious success is the atomic bomb programme on which a lot of money has been spent. Obviously Pakistan has mastered the science and technology of making bombs, but this does not signify that physics in Pakistan is in good shape. Making a bomb is a technology which is more than 60 years old and which can be acquired by any country if it is willing to spend vast amounts of money. However because of the atomic bomb project (which required purification and enrichment of uranium, the use of metals and alloys, development of triggers, control and real time fast data acquisition among others) and the requirements of rocket development and other defence needs, significant progress has been made in certain fields like geology, laser optics, electronics, chemistry, material sciences, plasma physics and computer technology. In general, the PAEC has been quite successful in its human resources development programme and has also set up a number of good research institutions for applications of nuclear energy in agriculture, medicine and industry. Also, together with the A. Q. Khan laboratories, PAEC has made more contributions to the defence industry, other than the development of the bomb, than the specially set up defence science organization, DESTO.

However in other fields of basic research the situation is truly dramatic. Research in the fundamental natural sciences of physics, chemistry, mathematics and biology is at a very low level, and falling. As mentioned above there is only one physics department worthy of the name and the same is true for chemistry. The one field where research has paid dividends to the nation is agriculture, where a significant portion of the state science budget was spent in the last 50 years. Several new varieties of wheat, cotton and pulses were developed. However this does not show in the impact factor analysis because most of the agricultural scientists publish in local journals. As stated earlier most of the so-called research institutions are not worthy of the name. In fact the situation is so dramatic at the time of writing that even an immediate injection of more money would not help to ameliorate the situation, as there are no scientists who could use this money productively. In fact the Pakistan Science Foundation in the last few years does not receive enough good research proposals to fund and ends up with money unspent.

There are essentially three explanations for why such a large number of institutions were not productive. One is that they were built by central planners without regard to availability of trained personnel. Good institutions are built around towering individuals or with the knowledge that there is a minimum critical mass of scientists in a particular field to support such an institution. If these conditions are not met the institution will be a failure unless immediate efforts are made to train a sufficient number of scientists very quickly. This is well illustrated by the few research institutes that do function in Pakistan. The HEJ Research Institute for Chemistry was built by Salimuzzaman Siddiqui, a renowned chemist, who was able to build up an excellent institute doing high-class research and producing good Ph.Ds. The institute also attracted other excellent young scientists to join it. The same is true for the Department of Physics at QAU, which was built by the internationally known physicist Riazuddin, who was fortunate, in the late 1960s, to have a pool of very talented young theoretical physicists working abroad at that time and who were willing to return. It is interesting to note the role of Abdus Salam, the Nobel Prize winner. Although he had not yet been awarded the prize at that time, he was already internationally renowned by the late 1950s and was able to attract a large number of Pakistanis to study at Imperial College. Riazuddin himself was a student of Salam. These young people formed the core of the newly established Physics Department at QAU in the late 1960s and the early 1970s. They helped to establish a tradition of research, which was absent in Pakistan until then, and it is being maintained. On the other hand when the PAEC was founded in the 1950s there were hardly any nuclear physicists in the country. However, here again Salam was crucial. He convinced the then Chairman, I. H. Usmani, to send a large number of students abroad to study physics. These people were guaranteed jobs in the PAEC and the strategy paid off. Secondly, institutions were regarded as a collection of buildings with a Director and a bureaucracy and a collection of research officers. Very little money was provided for actual research, i.e. for equipment, chemicals or libraries. The third reason why most of the institutions were unsuccessful was the development model followed in Pakistan after independence. The new institutions were not organically linked to the

industrial development of the country. Unlike India, which insisted on indigenous industrial development with protection for local industries, Pakistan followed World Bank and IMF advice in opening its markets to manufactured goods from the industrialized world. Apart from the textile industry and small-scale manufacture Pakistan did not try to industrialize. It still has only one steel mill to its name. Industrialists were encouraged to buy turnkey projects from abroad with no linkage to the scientific and technological base of the country. An additional reason was that the political leaders of Pakistan were never convinced of the importance of science. Science and education were never a priority in Pakistan. Unlike the enlightened leadership of Nehru and the Congress Party in India, who believed strongly in the transforming power of science, the Pakistani political class, consisting mainly of landlords, viewed science and technology as a luxury. Except for a brief period during Field-Marshal Ayub Khan's dictatorship not many resources have been set aside for the development of science and technology. The dramatic growth of R&D institutions during the Bhutto years had more to do with his populist ideas than a real commitment to science. Planners do not see science as a long-term investment for the future of the country, but rather as short-term costs.

Finally, there are cultural reasons why science has not taken root in Pakistan. At the time of independence Pakistan had only a few scientists and no culture of research and inquiry. Although the first can be addressed by sending people abroad to study, the second is a very delicate plant, which needs nurturing. Science is taught in schools and colleges as if it is something to memorize. Universities are still considered to be places where knowledge is imparted rather than where knowledge is discovered. To actively promote scientific discovery means giving researchers a supportive atmosphere for research: freedom from financial worries, freedom to travel to conferences and institutes abroad, good library facilities and good equipment. These have always been in short supply. All the blame of course does not lie with the government. Much of the blame lies with the scientists as well. Lacking a scientific culture and with the absence of peer review and competition many scientists regarded a Ph.D. as a certificate to retire. Being guaranteed a permanent job, many did not feel the inner necessity to do research and compete on the international level; they took the easy route of putting the blame on lack of resources even when this was not the case.

Given its track record up to now, the future of science looks very bleak in Pakistan unless something drastic is done. The only area developing rapidly is in computer sciences, particularly software development. There is now a boom fuelled by easy access to the Internet, relaxation of duties on computer parts, and by many private sector and government-funded institutes providing training. This is one sector where Pakistan can be truly competitive and there is hope it will take off. The other areas where science

should flourish are those related to defence and atomic energy, as a lot of resources are being diverted towards them. Since the success of the atomic bomb explosions in May 1998 Pakistan has committed even more resources towards the defence industry, particularly in rocket development. Much of Pakistan's science budget is hidden in the defence sector and surely this will lead to significant developments in certain fields related to rocketry and atomic bombs. However the quality and quantity of this kind of research is difficult to evaluate because of its very nature. It is true that the needs of defence have been one of the leading factors in the development of science and technology in industrialized countries over the last four hundred years. This dynamic was particularly evident in the United States, where massive spending on science after the Second World War was directly related to defence needs. Whether the same dynamic will occur in Pakistan, with research in defence-related industries acting as a motor for the general development in science, is still to be seen.

## SCIENCE AND TECHNOLOGY IN SRI LANKA

*Susantha Goonatilake*

### INTRODUCTION

The twentieth century began in Sri Lanka against the backdrop of certain events in the sphere of political economy as well as science and technology. There was a consolidation of British power after the fall of the Kandyan Kingdom in 1815, while forces of resistance continued to oppose British presence. These tensions were reflected throughout society, including in science and technology.

The United Kingdom was heir to a large reservoir of knowledge that had grown exponentially in the previous two centuries following the Industrial Revolution. Formalized knowledge of the physical world in Sri Lanka had many commonalities with the rest of the subcontinent. Some of this knowledge was ahead of the West until well into the twentieth century. And some, such as knowledge about plants, had passed through Garcia d'Orta and Linnaeus into a modern system of classification. In the late nineteenth and early twentieth centuries a new physics was being formed which required new orientations to reality. A nexus between the ideas of Western philosophers such as David Hume and Ernst Mach – key influences on Einstein and Schrödinger – and newly discovered South Asian philosophical sources, prepared the ground for the new physics.[1]

Thus S&T was a product of the interaction between Western interests and that of local reformers. Foremost among the latter was Angarika Dharmapala, the founder of international Buddhism, who wanted the establishment of industrial schools, the assimilation of modern S&T, and who rejected mere imitation. He recommended, among other things, learning from the Indian, Japanese and American experiences.

In the nineteenth century a few key institutions played an important role in introducing Western sciences. The Survey Department is an example. The Colombo Museum was established in 1877 with sections on history, biology, geology and mineral sciences. As part of the satellite gardens created around Kew Gardens, a Royal Botanic Gardens was established in Peradeniya. A Bacteriological Institute was established in 1900 (gradually transformed to become the Medical Research Institute in 1945). A Mineral Survey with Ananda Coomaraswamy as its head was formed in 1903. The latter, like Dharmapala, was influential in

pan-Asiatic debates, but unlike Dharmapala he rejected modern technology, sharing some parallels with Gandhi in this regard.

Large Buddhist monastic universities dating back to the pre-Christian era imparted lay knowledge as well. The last such large monastic university goes back to the sixteenth century. Such centres were re-established during the Buddhist Renaissance of the nineteenth-century: 1873 and 1875 being significant dates. Some of the nineteenth-century reformist monks were in touch with the major minds in the Western world at the time. However, the curricula these monks developed were still strongly oriented along traditional lines. In contrast, the Ceylon branch of the Royal Asiatic Society, founded by the British in 1844, became a clearinghouse for knowledge from both civilizations.

Westerners introduced and studied new plants in the early 1820s. This was the beginning of agricultural research. In the last half of the nineteenth century agricultural research related to the effects of pests, diseases, soil and climate on crop yields. Formal agriculture research began with an experimental station at Peradeniya in 1901, followed by a dry zone research station at Maha Illupallama in 1903. The Ceylon Agricultural Society, formed in 1905, led to the formation of the Department of Agriculture in 1912. By the latter half of the nineteenth century the British had established tea and rubber and some coconut plantations that were in Sri Lankan hands. Research Institutes for these crops were established respectively in 1910, 1918 and 1928.

### CENTRES OF RESEARCH AND SCIENCE POLICY

A Western medical school was first established in 1870 and a technical school was set up in 1893 to train lower-level technical cadres. The University College was founded to prepare students for University of London examination and was converted into a full-fledged university, the University of Ceylon, in 1942. The university system since then has expanded rapidly. A second campus was formed in 1949. Two of the centres formed in the nineteenth century as heirs to the ancient monastic universities were converted into Western-type universities and in the process lost their earlier monastic heritage. By the end of 1996 there were

12 national universities all teaching science subjects, while a few of them had attached faculties of (Western) medicine and/or engineering. There were also postgraduate institutes in the fields of agriculture, medicine, and science. By the end of the millennium (1994) these institutes were turning out 2,346 science graduates and 840 engineering graduates per year. At the same time (1995) the total number of students pursuing postgraduate courses in science-related subjects had increased to 1,730. Those offering postgraduate courses in medicine accounted for roughly half this figure, while agriculture science accounted for about 25 per cent.[2] But the expansion of both higher education as well as research in S&T had not resulted in a parallel increase in the country's proportionate expenditure on R&D. R&D expenditure reached a figure of Rupees 1,410 million (roughly US$31 million) in 1996 but as a percentage of the country's GDP had dropped from a figure of 0.3 percent in 1966 to 0.19 in 1997.[3]

Although organizations like the Royal Asiatic Society dated back to the early nineteenth century, a key fillip to the natural sciences was provided by the formation in 1941 of the Chemical Society of Ceylon. The members of this society then went on to establish the Ceylon Association for the Advancement of Science in 1944. This organization (later renamed the Sri Lanka Association for the Advancement of Science, SLAAS) has acted as a major forum for scientific discussions as well as the principal venue for the presentation of research results for most science disciplines. The SLAAS has been a major campaign forum for science policy related issues, resulting for example in the formation in 1968 of what is today named the National Science Foundation. There are also today individual professional associations for engineering, medicine, biology, physics, architecture, and surveying (as well as associations for several constituent sub-disciplines).

The desire of the scientific community to formulate and implement an effective science policy regime has not been realized. This has been largely due to a lack of high-level support. The closest any political regime came to supporting a serious science policy was with President J. R. Jayawardene in 1984. But this project collapsed because of the latter's lack of trust in his science advisor, a practicing chemist with a good career in the US, but without much insight into science policy or the local scientific community and its requirements or ethos. Scientists eventually rejected the policy plan. In the absence of a firm science policy, the system has been subject to many vicissitudes. Following a late start, it was hoped that some directions would have been the outcome of this policy perspective. The open market reforms of 1979 produced uncertainty that resulted in further transforming the environment of science and technology. The shift to an open economy from a protected, import substitution economy was not managed, as it had been in India or the Republic of Korea.

Previous policy initiatives directed at local capacity building in technology and the related attempts to install an industrial R&D system were now dismantled. It was cheaper and more convenient to buy technology off the foreign market than to develop local capacities. Similarly, successive governments initiated changes against the views of the local scientific community. These included the Science and Technology Development Act of 1994 and the establishment of a National Research Council in 1997. However, for the first time a Ministry of Science and Technology has been operational since 1994.

The output of S&T in Sri Lanka is difficult to measure. Given the small size of the community many sub-disciplines do not figure on the nation's S&T map. In some, such as disciplines like mathematics where sophisticated scientific equipment is not required, the number of researchers is so small that the system is sub-optimal. But in areas such as crop research there is a critical mass of researchers. Here research is sometimes applied directly. The three plantation crops of tea, rubber and coconut are funded by a tax on these crops, thus directly linking the outlay on research with the latter's contribution to output. There is also a dense network of connections between these local institutes and counterparts elsewhere.

In contrast, are the industrial research institutes such as the Ceylon Institute of Scientific and Industrial Research (CISIR) and the National Engineering Research and Development Centre (NERDC), established respectively in 1958 and 1974. The research output from these institutes has not fed the industrial system in a significant manner. Part of the reason is that industrialization has proceeded through the transfer of technology and has not responded to local technology inputs. The CISIR in the mean time has transferred some technologies to small-scale industries such as the food processing sector, for example in creamed coconut, cashew, chutneys, fruit jams, herbal toothpaste and mustard paste. But apart from this, the CISIR is limited to quality control and testing and troubleshooting in established industries. Further, both the CISIR and NERDC suffer from inadequate linkages with both industry and university academia.[4]

Another measure of scientific output is papers, for example those published in international journals and captured by the SCI, or papers presented at the Annual Sessions of the SLAAS following local peer review. There is no single journal in Sri Lanka that is captured by the SCI. SCI-cited publications have fluctuated in the last twenty years roughly between 100 and 200. Bangladesh produces around twice as many. In Sri Lanka, of the SCI included papers, physics and chemistry accounted for about 35 per cent, medicine 25 per cent, biology 25 per cent, agriculture 10 per cent and engineering 5 per cent.[5] The SCI is not necessarily a measure of excellence. It is basically a measure of recognition through peer review in the international community (meaning primarily in the Western world). But as in the classic case of the Indian mathematician Ramanujan, scientific excellence can be hidden for a long time from international recognition. Physics and chemistry constitute the bulk of Sri Lanka's research publications. Formal medicinal plant research had begun in the late 1930s and some physics research in the 1940s. This was largely a continuation of Ph.D. research undertaken by academics returning from their studies abroad. A major area of research with a large number of local and international publications has been in natural products chemistry using a strategic resource – plants. Other areas of research in chemistry include analytical chemistry, physical chemistry and environmental chemistry. There is virtually no research activity in organic synthesis, organometallic chemistry, theoretical chemistry and pharmaceutical chemistry. Research in physics has been relatively lacklustre, but the physicist C. Tennekoon, working in the area of photo catalysis and solar cells, has over 300 international publications in prestigious journals.[6]

In medicine, major areas of research include malaria, heart disease, intestinal diseases, agrochemical poisoning, maternal and child health, viral infections, stress in armed conflicts, nutrition, filariasis, reproductive health and rheumatic heart disease. The fact that the country is infested with malaria has prompted the development of an important research centre at Colombo University. A strongly motivated researcher, Kamini Mendis, leads the centre. The centre has forged a strategic partnership with WHO, and its members are in communication with other such centres around the world. The group is highly productive and is in the global forefront of malaria research. The costs in international terms have been low.[7]

Agricultural research is conducted by a large number of organizations, over ten ministries and several statutory bodies. Further, the formation of the Postgraduate Institute of Agriculture in 1975 was a significant step. By the year 2000, the Institute had undertaken over 200 research projects. Around 55 crops were covered in agricultural research. These include crops outside the main ones of rice, tea, rubber and coconut – such as horticultural crops, cut flowers, foliage plants, and vegetables. The technical manpower is spread out over several institutes. However, since the infrastructure is limited and shared by several institutes, it is difficult to operate a large number of research projects. In the case of plantation crops, research and extension have been closely linked, resulting in the rapid uptake of research results and thus productivity increases. By the late 1990s, links between university-based agricultural research and the research undertaken by the Departments of Agriculture and Export Agriculture were formalized with the objective of promoting research efforts and accelerating the adoption of technology.[8]

The Asian Development Bank has funded an important five-year programme designed to strengthen local human resources in selected key areas. The aim is to develop centres of excellence in selected institutions that are internationally competitive. This involves the training of selected persons abroad for postgraduate research and the elimination of bureaucratic delays blocking the training schedules of scientists. The Ministry of Science and Technology has recently created a Technology Transfer Unit that manages a research fund for innovative pilot projects, and promotes innovation clubs in schools and universities and the establishment of technology parks at industrial research organizations and universities, and it is now suggested that university-based companies be set up.[9]

As Sri Lanka is becoming assimilated into the economy of the Asian region, aspects of her traditional – both indigenous and modern – knowledge systems are now being emphasized. Traditional botanical and herbal knowledge is now of significance for chemical research on natural products. Attempts are being made to bridge the gap between modern science and useful aspects of Sri Lanka's classical heritage. Aspects of Buddhist psychology have been researched in Western laboratories and are found to be of relevance for contemporary practice. But this programme of bridge building has had some unfortunate aspects. Some none-too-rigorous scientific programmes have been taken up at research institutes. Granville Dharmawardene and key members of the SLAAS Popularization of Science Committee have been propagating the idea that there is allegedly evidence of past lives based on recovered memories under hypnosis. This is after decades of scientific debunking of such claims in the West. In the same vein, Chandana Jayaratne, a popularizer of science of the SLAAS, supported the local claim that the ancient Buddhist stupas at Anuradhapura, the largest brick structures in the world, were built by aliens. The map of science in Sri Lanka remains patchy.

Over fifty years ago, Sri Lanka generally solved her problems concerning access to primary education. This is in contrast to India, which decided to forego universal literacy to build a viable S&T system and community. But the educated Indian population has relatively good and efficient access to both Indian and international discussions on scientific knowledge, which feed both their public as well as their S&T practitioners. Indians have broad access to sophisticated discussions on S&T and their social context in Indian newspapers. This is quite in contrast to Sri Lanka, where science has been disseminated locally through the school system and the university structure, albeit sometimes unevenly. A contributing factor has been the shift to local languages as a medium of instruction in the universities. This change has been introduced without adequate translations of pedagogic material into the local languages.

Uninformed intermediaries in the news media often initiate public discussion on S&T related issues. The worst offenders are the state newspapers, a case in point being Sri Lanka's *Sunday Observer*. For example, the major crisis in Sri Lankan public life has been the ethnic strife that has now extended over decades. The newspaper distorts its reporting to suit the ruling ideology. But this situation is changing, due in part to the more positive side of globalization. For example, 'Discovery' programmes are beamed through state channels directly to Sri Lankan homes in the two languages of Sinhala and Tamil. The 'Discovery' package may be Eurocentric and leave out non-Western, and more narrowly Sri Lankan interests, but it helps shed local blinkers.

## CONCLUSION

Sri Lankan S&T capacity can be characterized as relatively developed in areas such as crops research or in applied engineering and medicine. But in other areas, it is patchy. Over the years there has been an increase in funding for research in the physical and chemical sciences. But a major impediment appears to be lack of good ideas and proposals. In the absence of good research proposals, weak proposals are often approved.[10] Weak funding, inadequate local exposure to international and local debates, lack of growth of viable and self-reinforcing sub-communities without continuous accumulation of knowledge characterize many other fields.[11] There is also a tendency among some senior academics to discontinue research once they have been awarded their last promotions.[12] Despite all these drawbacks, S&T in Sri Lanka seems healthy for a middle-level developing country. But from the point of view of the requirements of the country as well as science, this is inadequate. After all, Sri Lanka has life expectancies that match those of developed countries and is well placed with respect to the other quality of life and social indicators.

## SCIENCE AND TECHNOLOGY IN SOUTH-EAST ASIA

*Suzanne Moon*

### INTRODUCTION

In early-twentieth-century South-East Asia, state bureaucracies became crucial players in the spread of science throughout the region. Those governing the colonial and non-colonial states of South-East Asia followed the lead of governments around the world, who saw science as the key to more efficient state management, and to the material and social transformation of their societies.[1] Governments established scientific bureaucracies to inform policy in areas like agriculture, forestry, and health. For the state, scientific methods made it possible to 'see' people and resources in simplified ways, which focused on only those aspects specifically related to state objectives, making manageable the complexity of the real world.[2] For example, scientific foresters characterized forests by board-feet of different woods and estimated yields over time, thereby defining and managing 'timber resources'.[3] In South-East Asia, science offered an efficient way to manage resources, an important goal given that the region relied heavily on raw material production to fill state coffers. States used science to manage populations as well. Anthropological studies of ethnic communities suggested divisions the state could use to organize and control their populations, which in turn popularly reinforced social divisions that had previously been more fluid.[4]

In South-East Asia, scientific bureaucracies started to emerge in the late nineteenth century. The Netherlands East Indies Department of Public Works had become fully managed by technical experts by 1885, and a scientific Department of Agriculture was created in 1905. British Malaya had Departments of Health and Chemistry by the late 1890s and a Department of Agriculture in 1905. The American Philippines started a Bureau of Science in 1912. Thailand, with help from the Rockefeller Foundation, started a medical training school in 1917.[5] Such institutions provided not only a place for science, but also local questions for science to address. In Europe, universities played this role; in South-East Asia there were few universities before 1900. Science in the region had usually been practiced in enclaves, operated by Europeans for their business interests or to further European scientific careers. Private planters' organizations, for example the sugar industry on Java and the rubber industry in Malaya, supported research stations.

Otherwise, Western scientists travelled to the region for field research in areas as diverse as geophysics, astronomy, anthropology and botany.[6] These institutions rarely penetrated local societies; they were neither meant to train local people in great number, nor make science a part of indigenous life.

In contrast, state-supported scientific institutions penetrated more deeply into the life of South-East Asian societies, changing the science and the societies themselves. This was especially true for science practiced for 'development'. 'Development' is a slippery term, but often meant the improvement of the economic life of ordinary people, who were seen by state authorities as lacking the means or motivation to improve their own economic positions.[7] Authorities identified groups of people who did not seem to fit into society as the state thought they should, whether because they lived lives of greater economic and material hardship than others, or because they did not accept the goals set out by the state. Development programmes might, for example, reorient subsistence producers toward cash economies, giving them (in theory, although rarely in practice) more income and the state more tax revenue. Development projects were, like scientific bureaucracies, a global phenomenon. In the United States for example, backers of the 'Country Life Movement' (1908), brought modern technologies to the American countryside in order to stem a worrisome migration to cities. The young Soviet state undertook tractorization and electrification projects in the early 1920s to overcome their self-perceived backwardness.[8] In the eyes of authorities (although the public did not always share their views) such projects were beneficent, promoting the rational exploitation of peoples and places, and justifying the authority of government. In South-East Asia, colonial powers made scientific development projects part of 'civilizing missions' meant to materially demonstrate the wisdom of colonial authority.[9] Thailand embraced science and technology under the rule of Chulalongkorn, to strengthen the Thai state in its confrontation with colonial powers.[10]

Because bureaucracies of development were created to solve local problems, science became a larger part of life in South-East Asia under their influence than when scientific institutions were European enclaves. Development projects often opened some forms of scientific careers to indigenous

people. Laboratories and experiment stations employed indigenous people as technicians, making science dependent on indigenous labour. Better-educated indigenous people became crucial to the success of development, using their training in science and familiarity with local cultures to mediate between laboratory scientists and ordinary people. Participating in science created a worldview among these young elites that separated them from their older counterparts, inculcating a belief in the power of science to solve social problems.[11] These mediators in turn introduced scientific ideas and methodologies to ordinary people through education programmes. The numbers of people who could enter the ranks of the scientifically trained was not high, and the depth to which their work penetrated daily society varied. Nevertheless, the work of such mediators did make science a recognizable part of South-East Asian life in the twentieth century, opening a place, if a small one, for Western-style science in indigenous society. The transition of science from an enclave practice to an integrated part of a South-East Asian society is demonstrated by the case of Indonesia, where the transformation of the enclave of the Royal Botanical Gardens in Buitenzorg (later Bogor) into the Netherlands East Indies Department of Agriculture opened an enduring institutional space for indigenous people to practice science aimed at the needs of local society.

## SCIENCE IN THE NETHERLANDS EAST INDIES: THE TRANSFORMATION OF AN ENCLAVE

In 1900, the Royal Botanical Gardens at Buitenzorg on Java, was a premier scientific institution in South-East Asia.[12] As was typical for botanical gardens in the tropics, the gardens in Buitenzorg were operated as an enclave of European science. The transformation of this enclave came about largely in order to obtain a more secure place for science in the colonial bureaucracy. While focused on botany, the gardens were never run solely as a 'useful' enterprise, or one from which the state expected to reap profits. Initially established in 1817, the gardens were operated at the pleasure of the king and only in 1843 were they incorporated into the bureaucracy of the Netherlands East Indies government. The gardens during these years collected tropical plants and exchanged plant materials with Dutch universities, maintaining a modest scientific profile for the increase of botanical knowledge.[13] The botanical gardens were constantly vulnerable to budget cutbacks because of the charge that their work was not tied to the business of the colony.

This began to change when Melchior Treub took over the post of director in 1880.[14] Treub sought to increase the international prestige of the institution, and give it a solid foothold in colonial administration. In doing so he walked a careful line between maintaining the scientific independence of the gardens and providing useful science for the colony. Before Treub took over, the gardens had experienced a notable success with the cultivation of cinchona trees, the source of quinine, the only known prophylactic for malaria. Some pragmatists insisted that the gardens should be used for discovering and cultivating new plants for export agriculture. Treub had an entirely different vision for making a place for science in colonial administration. He

created laboratories and fields designed especially for experimental plant sciences, like plant physiology, and pathology, entomology, and soil chemistry, contrasting sharply with the older tradition of building collections of tropical plants. By setting up experimental facilities in new areas of research, Treub made the gardens a place from which a scientist could build a reputable career far from Europe, something that was quite difficult to do.[15] While tropical areas had been long recognized as a storehouse of botanical riches, scientists usually collected, rather than analyzed, data there.[16] Scientifically, Treub's facilities supported world-class scientists in their research, adding to the prestige of the Indies. Institutionally, Treub's gardens became a place for the ongoing support of cutting-edge science in the colony.[17]

The prestige of the gardens helped secure them a place in colonial bureaucracy, but did not eliminate their vulnerability. Treub built a stronger case for the gardens by having scientists work voluntarily (but not exclusively) on problems afflicting export crops. Most dramatic were their contributions to understanding the sugar cane disease *sereh*, which had brought Java's sugar industry almost to a standstill in the 1880s.[18] At the same time, Treub ensured the scientific independence of the gardens by vesting the director (himself) with sole authority on scientific matters, freeing the science from any direction by their bureaucratic heads in the Department of Education, Religion and Industry. Treub made the gardens useful without jeopardizing the independent actions of scientists.

Treub reinvented the Botanical Gardens as a premier scientific institution whose agenda was controlled internally, but it remained a European enclave. Indigenous people played none but the lowest-level roles in the institute, doing menial labour in experiment fields or laboratories. Introducing science to the colonized people, even elites, was not part of Treub's vision for colonial science. For educated members of indigenous society, science was not a typical career. The most promising positions were in the Native branch of the civil service and law was the training of choice.[19] This began to change as an indirect result of a set of administrative reforms that came to be known as the Ethical policies. As the government began to call for greater attention to the welfare of indigenous people – or what was called 'the development of the Native peoples' – the possibility of using science for Native development became a popular idea. It was from the spread of scientific Native development that the possibility of scientific careers for indigenous people emerged.

That possibility did not emerge immediately. While the more socially ambitious ethical policies aimed to expand the political role of indigenous people, introduce press freedoms, and encourage Western education for indigenous youth, Native development also included projects meant to improve the material, or economic well-being of the people. Treub argued that the same scientific approach that worked for export agriculture could be applied to indigenous agriculture, and that such work should be done by a comprehensive Department of Agriculture, which would become the sole scientific authority for all agriculture in the colony.[20] Treub based his proposal in part on the United States Department of Agriculture and in part on the existing Botanical Gardens that would be subsumed into the new department. Treub's proposal put science in the service of indigenous agriculture, and also secured a long-term place

for science in the colony, since the department would advise on agriculture, the primary business of the colony. Treub argued that both export crops, which were facing serious international competition, and indigenous crops, which provided a significant portion of the colony's food supply, required the kind of experimental science he had developed at Buitenzorg to make food and export production optimally productive and remunerative.

The debate over whether to form a Department of Agriculture revolved around the question of how useful such a department would be for the indigenous people, and Native development. A few representatives of the civil service argued that scientists would always be serving two masters: their scientific careers and indigenous farmers. How could anyone trust scientists not to put their own careers and the 'interesting' work of science before the needs of the Native peoples?[21] In a related critique, some argued that while the civil service had contact with the people on a regular basis, scientists as a rule did not. How could scientists serve the best interests of farmers when they didn't know the farmers?[22] Treub's gardens had always been a European enclave, his proposal therefore had little to say about just how farmers would access the scientific knowledge he envisioned emerging from his department. Support for the Department far outweighed criticism however, and in 1905 the Minister of the Colonies in the Netherlands approved the creation of the Department of Agriculture with Melchior Treub as its first Director. Treub succeeded in creating a bureaucratically secure place for the practice of science in the colony, but the issue of Native development placed the Department under much more public scrutiny than the Gardens had ever experienced. The questions raised by early critics about the ways the Department would interact with the indigenous peoples would become a central issue that shaped the ways that science was practiced, and who would have the opportunity to practice it, in the East Indies.

## 'CLOSE CONTACT' – THE DEBATES OVER SCIENCE AND NATIVE DEVELOPMENT

Treub organized the new department, including the section for investigations into Native agriculture, much as he had the Botanical Gardens. The emphasis was on scientific experiment and fact-gathering. For example, one of his first actions was to collect samples of all the different kinds of rice grown on Java, and have an investigator catalogue the unique varieties, as a prelude to selecting the most high-yielding varieties for distribution to farmers.[23] Yet the project of Native development posed a problem of dissemination that Treub had not previously faced. When dealing with European planters, Treub faced a small, educated audience who would follow the results of relevant scientific work with little or no prompting. Indigenous farmers differed dramatically. Not only were there far more people involved – agriculture accounted for the livelihoods of greater than 90 per cent of the indigenous population – they had no culturally inculcated faith in science, nor the means to easily follow scientific debates. Nineteenth-century agricultural improvement projects organized by civil servants had usually been ineffective at best, and disastrous at worst as civil servants tried to compel

participation in scientifically questionable projects. Ordinary farmers had little reason to find government representatives credible. Treub opposed compulsion, finding it unjust, ineffective, and for his own work, unnecessary.[24] Treub had a dual approach to solving credibility problems. First, he made sure that experimental work, anything that might provoke incorrect interpretations by non-experts, be done at locations closed to farmers. Public demonstrations would involve only proven technologies. Second, he held demonstrations not for farmers, but for members of the indigenous ruling hierarchy. Treub believed that farmers would take the word of their leaders far more readily than that of Europeans. He used indigenous leaders as intermediaries between the Dutch and the Indies peasants much as Dutch colonial government had done for years.[25] Treub's methods, relying so much on colonial tradition, did not please ethical reformers.

Ethical reformers complained most about Treub's model of dissemination. They wanted fast, almost revolutionary change in indigenous agriculture, reaching further into the countryside than the nine demonstration fields established by Treub could do. One study noted that Java would need nearly 8,000 demonstration fields for it to have proportionally as many as the Netherlands did.[26] The problem was not only quantity, but also method. Ethical reformers were committed to an ideal of the colonizers as tutors for the colonized, promoting 'close contact' between the Dutch and indigenous people, which they believed would produce better social relations in the colony. Treub's system of indirect contact did not satisfy these ideals.

In ill health, Treub resigned in 1909, and was replaced by Herman Lovink, a man whose priorities matched those of Ethical reformers more closely than had Treub's. A Dutch bureaucrat who was not himself a scientist, Lovink had headed the Ministry of Agriculture in the Netherlands and enthusiastically supported the creation of an agricultural extension service in the Indies in 1911.[27] Under Lovink, the department operated far more demonstration sites, and blurred the distinction between experiment and demonstration. Both were run on fields that were open to the public, producing the desired close contact between representatives of the Department of Agriculture and Javanese farmers.

Lovink's initiative played a crucial role in transforming the enclave-like operation of the Department of Agriculture into an institution which supported scientific training and employment for indigenous people. Locally trained indigenous extension specialists became crucial to the working of demonstrations across Java. Lovink did not rely solely on Dutch specialists for two reasons. Pragmatically, it would have been expensive to hire the number of Europeans necessary for the task of extension as Lovink envisioned it. More importantly, Dutch extension specialists, trained primarily in science, were less well-equipped than educated indigenous people to negotiate the cultural and linguistic barriers between colonial scientists and indigenous farmers. Indigenous extension specialists became indispensable mediators between these two groups. Trained in Western science, but raised in indigenous society, these mediators could effectively translate both the language and intent of Western science to indigenous peoples.[28] Extension specialists ran schools for farm children, occasionally designed demonstrations, supervised demonstration fields, and practiced most of the 'close contact', i.e. talking to

farmers and encouraging them to adopt new techniques and materials recommended by the Department. Indigenous extension specialists, while admittedly not at the top of the scientific hierarchy, nonetheless became an essential cog in the project of Native development.

The spread of indigenous scientific mediators had a significant effect on the spread of scientific agriculture, by encouraging changes to practice, and by making the scientific approach more familiar to farmers. Extension specialists in charge of demonstration fields established relationships with farmers, whose land they often used, and explained the purposes and methods of the demonstrations. They also worked in agriculture schools, which often operated small demonstrations, therefore offering to some rural students an introduction to scientific agriculture. Exactly how 'scientific' this education was did change over time. While in the 1910s there was a good deal of emphasis on providing a theoretical understandings of plant biology, by the 1920s officials in the Department revised the training to be more 'pragmatic', focusing on the operation of experiments, and excluding study of the underpinning biological theories.[29] This change limited the wider spread of scientific education, even though students did gain some exposure to scientific methods. There is evidence that by the 1920s indigenous society had started to embrace the promise of science. Leaders in the royal principalities of Yogyakarta and Surakarta organized their own demonstration fields. Some villages made special requests for help in organizing their own demonstrations. One anonymous farmer in the 1920s argued that wealthy farmers should send their children to Europe for agricultural education to bring back the most modern methods.[30]

'Close contact' and the indigenous extension specialists did not just spread scientific thinking, they also made certain kinds of knowledge-production possible. As the extension service began to do demonstrations across Java, they gained a detailed view of the differences in climate, soil, water, and agricultural practice across the island. While some 'demonstrations' were intended to show the superiority of high-yielding seed varieties, extension workers often discovered instead the extent to which regional variations affected the yield of those varieties.[31] What had started as a search for a few high-yielding varieties of rice, became instead an effort to discover which varieties of rice would grow best in which areas. Consequently, demonstrations became experimental, comparatively exploring the outcomes of regimes of seed varieties, fertilizers, irrigation methods, and rotations for particular locales. Later, with the advent of agricultural economics, extension specialists expanded their studies to the economic life of villages, striving to gain a systemic understanding of agriculture, from the composition of soil, to the details of economic behaviour. This detailed scientific view of Java's agricultural landscape would have been impossible without the corps of indigenous and European extension specialists.

Demonstration/experiments done for Native development provided a modest but significant way for farmers' opinions to influence the projects as well. As extension specialists ran comparison tests of rice and other crops, they discovered that indigenous farmers valued – far more than yield – appearance, flavour, speed of ripening, and ease of harvest, for example. While the Department itself continued to espouse the philosophy that yield improvement was the primary goal, extension specialists had to modify that goal on the ground to meet the expectations and habits of farmers. The goals of Native development stayed the same, but its actual results were shaped by farmers' input to the process.

The scientific work of the Department was not lost on indigenous political activists in the Indies, although it did not target this largely urban group of reformers. Many Indonesian activists embraced the promise of science (and some, including Sukarno, the engineer who would become Indonesia's first president, were trained in technical fields). Activists did question however, whether the science was truly being used in the best interest of Indonesians. One critic named Darsono roundly criticized the agricultural extension service for offering advice that was useful only to wealthy farmers.[32] Darsono dismissed farmers who listened to Dutch extension specialists as 'bootlickers', but at the same time endorsed the trustworthiness of Native extension workers. For Darsono, the problem was not the science, but the motivations of those who disseminated it. A similar point was made by one critic who identified himself only as a Realpolitiker in a debate on the subject published in the newspaper *Daulat Ra' jat*. He argued that the Dutch would manipulate any change so that ultimately it did not benefit the people, but the Dutch alone.[33] Nevertheless, both he and his opponent agreed that science would be useful. Realpolitikers, however, argued that this would not happen until after the revolution, when the science was in the hands of Indonesians alone. Revolutionaries by and large saw science as a useful tool if it was independent of colonial control.

## THE LEGACY OF THE NETHERLANDS EAST INDIES DEPARTMENT OF AGRICULTURE

Development projects in the Netherlands East Indies, as in much of the rest of the colonial world, did not achieve a wholesale transformation of indigenous economic life.[34] Yet development work did provide the motivation to transform enclave-like institutions of scientific practice into bureaucratic institutions that reached more deeply into indigenous society. In the Indies, more indigenous people had access to scientific education, and a few were able to pursue scientific careers without going to Europe, something that would have been impossible in the nineteenth century. Most Indonesians, like most Dutch people, began to accept the promise of science as an agent of social change, even when disagreeing on what kind of social change was desirable. When the Republic of Indonesia began to construct its independent government in 1945, it duplicated existing scientific departments such as agriculture, and staffed them largely with those trained during the colonial era. In so doing it gave priority to maintaining the infrastructure of science for development. Although sending many students abroad, and welcoming aid and advice from agencies like the United States Technical Cooperation Administration (later the US Agency for International Development), the new Indonesian Ministry of Agriculture drew significantly on the scientific traditions of the colonial Department of Agriculture. Indeed scientific exchange has remained a prominent way that independent Indonesia has maintained ties to the Netherlands.

Across South-East Asia, science was able to play a deeper role in societies because it gained a stable place within state bureaucracies. These bureaucracies offered scientific careers, and eventually motivated the growth of educational institutions like the Technical University of Bandung in Indonesia, and Chulalongkorn University in Thailand. While this kind of support has allowed far more people to be educated in science than during the early twentieth century, it must be noted that there are still serious obstacles to the pursuit of scientific professions in South-East Asia. In Indonesia for example, higher education is expensive and out of reach for the vast majority of people. The most prestigious science degrees are usually those from foreign universities, placing yet another barrier in the way of the most ambitious students. This being said, the establishment of state bureaucracies did end science as a purely Western enclave and foreign practice. Science in South-East Asia has grown indigenous roots, which continue to inform and transform the Western scientific tradition.

## NOTES

1.  To give just a few examples, the United States had established its Department of Agriculture in 1862, which contained among other sub-departments, a department of chemistry for research into food and drug safety. Scientific forestry emerged as a tool for government in Saxony and Prussia in the late eighteenth century. For an interesting analysis of the importance of such scientific bureaucracies to democratic societies see Y. Ezrahi, *The Descent of Icarus: Science and the Transformation of Contemporary Democracy*, Cambridge, MA, 1990.

## CONCLUSION

*Dhruv Raina* and *Syed Irfan Habib*

By the middle decades of the twentieth century, most parts of South and South-East Asia were endowed with institutions of scientific and technological research. Researchers working at these institutions had joined a global scientific community with socio-intellectual ties extending over long distances. At the end of the twentieth century it then became pertinent to ask how these institutions were functioning in comparison with institutes in the developed world. How much had the societies of these regions benefited from science? In other words how much of the rhetorical promise of science was transformed into public good. And finally, what was the impact of scientific research undertaken in the region on world science?

As will be evident from the preceding articles, it appears that in certain areas of the sciences the institutions of research in different nations of the South and South-East Asian region have made a notable impact in the world of science. Further, depending on the resource endowment of the region, a degree of specialization has been achieved through institutions that have dedicated themselves to focused research, and through ties with the related strategic industrial networks of the area. While India appears to have benefited the most in terms of its dense network of institutions, it still appears to have a long distance to traverse in terms of making a significant mark in terms of impact indicators.

A study undertaken by Thomas Schott on the nature of ties between the centres of science in the United States and the rest of the world has some interesting insights to offer.[1] The study suggests that the globalization of science is not identical with the process of equalization. Sociologists of science have posed the question whether science lives up to the promise of being a public good, and if it does, for whom.[2] Science becomes a public good when the necessary infrastructure, research training, material and cultural facilities are simultaneously available, in order to render the entire system capable of participating as equal partners in the generation of scientific knowledge. The fact that the resources for scientific and technological research in the two regions are available but are spread out thinly has generated few institutes of excellence that manage to keep pace with developments at the international research front, or with cutting-edge research, or world-class research.[3] Other than

these islands of excellence, as in the period of colonial rule, the system of world science crystallizes into a centre-periphery formation. This has meant that while the periphery produces people who fit into research positions at the centres of science, the ideas themselves migrate from the centre to the periphery and influence research and research priorities at the periphery.[4]

If one takes the case of the South Asian region, no scientist has received the Nobel Prize in the sciences since 1933. During the postcolonial period three scientists who received their early education in the region, but who pursued their scientific careers in the West, were awarded the Nobel Prize: two for physics and one for medicine. This itself is an indicator of the difficulties encountered in pursuing science at the periphery and the constraints posed by the politicization of Big Science. We would like to mention two important findings that have come out of Schott's survey. A study of the nature of collaboration between the different regions of the world indicated that collaboration between institutions within a country has not grown as rapidly as foreign collaboration; and this is particularly true of the developing regions of the world. As a consequence, it appears that long-distance ties between scientists have grown much faster than ties between scientists of neighbouring nations.[5]

The concentration of research resources in institutes dedicated solely to research is reflected in the gradual displacement of the university as the primary site of knowledge production. Scientometric studies undertaken in India reveal that in the more advanced areas of scientific and technological research, the major contributions to scientific research come from the research institutes.[6] The universities still manage to hold the line in a few traditional research areas. This breakdown of the Humboldtian model of the university in the region has consequences whose impact still needs deciphering. Simultaneously, governments have been pressuring ministries and agencies of science and technology to restructure both organizationally and in terms of research priorities. This has many implications for research practices, research budgets and research priorities.

While these changes and pressures are manifest in most regions of the world, they acquire a crucial significance where

research systems have just begun to acquire stability, and in environments where they are suboptimal. But more than anything else this structural crisis has resulted in the marginalization of the social agenda due to science within policy discourse on science. The crisis due to the dysfunction of the scientific and technological research system in the 1970s generated an entire debate on 'relevant research' from within the scientific community.[7] The rhetoric of legitimation and the policy environment of science today reveal axiomatic differences, wherein the social contract of science is being drafted differently. Furthermore, the changing geopolitical scenario of the region has resulted in the reallocation of budgets towards research in security- and defence-related areas. Put another way, there are more resources available under the umbrella of defence-related research. These developments strain resources that could well be committed to the developmental requirements of South Asia. India and Pakistan have demonstrated nuclear capabilities, exacerbating the proliferation of nuclear weapons capabilities and the threat of nuclear war in the region. This is not to suggest that broad fronts of scientists and citizens across the border have not been campaigning for nuclear disarmament.

However, globalization has also opened new windows and opportunities in the information and biotechnology sectors. The region is able to produce a sufficient number of graduate students who can take up jobs to meet the demand of the information and biotechnology industrial sectors in the West. This has produced large-scale migration of graduate engineers and scientists from the South Asian region to the West. Furthermore, over the last couple of years some leading infotech giants from the United States have commenced shifting their R&D facilities to India particularly. While this is an indication of the pace and dimensions of globalization, it is too early to tell which of the two processes, the relocation of R&D facilities or the large-scale migration of trained technical professionals,

prevails. Leading institutes of technology and scientific research in India have worked out arrangements with universities and polytechnics in Europe for exchanging students and the pursuit of doctoral degrees abroad. This continues to pump the universities of the West, where doctoral enrolments are declining, with fresh blood. Hopefully, this exchange would also endow the institutes of these regions with infrastructure and integrate them more strongly into networks of 'cutting-edge research.' The next few decades will reveal whether these regions have entered the world of global science as equal partners.

Bahodor Iskandorovich Iskandarov*

## INTRODUCTION

East Asia entered the twentieth century through two wars: the First Sino-Japanese War, from 1894 to 1895 and the Russo-Japanese War, from 1904 to 1905. Although these two wars were related, they had different meanings and impacts. In the pre-modern period, China was the pre-eminent power in East Asia, and regional politics revolved around the Qing Dynasty, the last Imperial Manchurian dynasty to rule (1644–1911). This was an isolated system and had little contact with international systems in the other regions. The nineteenth century Opium Wars between China and Britain (1839–42, 1856–60) were the first ever assault from Western capitalism on the established system. The First Sino-Japanese War symbolized the total collapse of this system: China's last tributary state, Korea, now severed its former relationship and came under Japan's sphere of influence. Japanese military power, which had been developing since the Meiji Restoration in 1878, now exerted itself across the Asian continent. Japan defeated the corrupt and decaying Qing Government. The Western powers, however, still did not recognize that Japan was an equal player on the international stage. The Russo-Japanese War was a war for supremacy in East Asia, and Russia's loss enabled Japan to establish itself as an equal with Western powers. Britain, France and Germany had their own spheres of influence in the Asian continent, and they could do little in Northeast Asia. In spite of the Open Door Doctrine put forward by US Secretary of State John Hay in 1899, the United States was not in a position to compete with Japan in the region, and its major concern was to consolidate its position in the Philippines. Because of that, the United States made concession after concession to Japan during the first two decades of the twentieth century, allowing Japan first to take Korea as its protectorate, then to formally annex it in 1910, thus beginning its half century of colonial rule there.

The Boxer Rebellion in China at the very end of the nineteenth century was the last major confrontation between the Late Qing China and the Western powers and expedited the collapse of the feudal Qing rule. Dr. Sun Yat-sen successfully led the Revolution of 1911 in Southern China and established the Republic of China. But the situation was far from stable. With support from the foreign powers, General Yuan Shikai, who used to work for the Qing Dynasty, usurped the power. Yuan Shikai was dreaming of restoring the imperial system and tried hard to get foreign support. Japan was eager to turn China into its actual protectorate and took this opportunity to present the infamous Twenty-one Demands to Yuan's government. Both Yuan's shameless drive for emperorship and Japan's Twenty-one Demands aroused public indignation throughout China, and Yuan's dream was shattered. He died in 1916.

After Yuan's death nobody could control the Northern warlords, and China entered a period of internecine wars that were complicated by the foreign powers' competing for influence and supporting different warlords: Japan backed the Northeast and Anhui warlords, and America and Britain backed the Hebei warlords.

During the First World War the Western powers were busy in Europe and could not spare much attention in China. Using this opportunity Japan sent troops and occupied the leased territory of Germany in Jiaozhou (Qingdao) and the Jiaozhou to Jinan railway. At the Versailles Peace Conference in 1919, the Chinese delegates requested the return of the rights and interests seized by Japan during the First World War in Shandong province. The Western powers, for different reasons, supported the Japanese demands. The Chinese people's indignation erupted violently and the students in Beijing and everywhere held demonstrations, followed by workers' protests. This was the May Fourth Movement, which had profound significance in modern Chinese history. Backed by the Chinese people, the Chinese delegates to the Versailles Peace Conference refused to sign the treaty with Germany and said a loud 'No' to foreign powers for the first time in modern Chinese history.

The Versailles Peace Conference did not solve the outstanding issues between China and Japan and the situation in East Asia remained disturbing. After the end of the First World War the Western powers were eager to return to Asia and could no longer tolerate the Japanese expansion there. In 1922 at the Washington Conference on disarmament, the so-called Nine Power Treaty was concluded and Japan's aggression against China was checked. China returned to sharing its dominance with foreign powers.

The First World War made the Chinese intelligentsia disenchanted with capitalism, and Marxism as a new theory and world outlook spread rapidly. The Communist Party of China (CPC) was established in 1921.

Dr. Sun Yat-sen established his revolutionary base in Southern China and waged a tenacious struggle against the Northern warlords, but he suffered setback after setback. The bitter experience led him to believe that without support and cooperation of the Soviet Union and the CPC he would not prevail. He advocated 'uniting with CPC, uniting with the Soviet Union and supporting workers and peasants'. Having devoted all his wisdom and energy to the cause of the Chinese revolution, he passed away in 1925.

Cooperation between the Kuomintang (KMT) and the CPC changed the nature of the Chinese revolution and greatly expedited its process. In 1926 and 1927 the revolution won a significant victory in its struggle against Northern warlords. In April 1927 Chiang Kai-shek, who possessed military power, launched a coup d'etat, expelled the Communists, and put down the peasants and workers' movement. In 1927 he set up the Nationalist government in Nanjing. Between 1927 and 1937, before the outbreak of the War of Resistance against Japan, or the Second Sino-Japanese War, the Nationalist government achieved considerable success in promoting China's economic recovery and development.

The CPC's countermeasure was to stage the Nanchang Uprising in August 1927 and set up its headquarters in the Jinggangshan Mountain. Thus began the Civil War between the KMT and CPC, which lasted for ten years. Facing encirclement by the KMT, the CPC carried out a grand strategic transfer and completed the Long March during 1935 and 1936. The revolutionary base area moved to Northern Shan'xi province.

Japan was unsatisfied with the arrangement reached at the Washington Conference, and seizing the opportunity provided by the economic crises throughout the world in the late 1920s and early 1930s, conspired to attack the Chinese in 1931 in an assault known as the Manchurian Incident (18 September Incident). The Nationalist government's non-resistance policy and Western powers' weak response further emboldened the Japanese aggressors, and they rapidly occupied the whole of Northeast China. The US Secretary of State Henry Stimson sent a note to Japan announcing that the United States would not recognize the legitimacy of this change of situation nor any treaties and agreements between Japan and China which ran counter to the Open Door Doctrine.

Japan was not satisfied with its success and engineered the Marco Polo Bridge Incident (Lugouqiao Incident) in July 1937. In its aftermath Japan launched a full-scale war against China. Facing the danger of national subjugation, the KMT and CPC both realized the need to cooperate and thus began the War of Resistance against Japan.

Japan's purpose was to dominate the whole of East Asia and eliminate Western influence from the region. On 7 December 1941 Japan made a sneak attack on the US naval base at Pearl Harbor in Hawaii and the British colonies in Asia. The United States proclaimed war on Japan, and the battle for the Pacific began. In November 1943 the leaders of the United States, Great Britain and China met in Cairo and discussed the war against Japan. The Cairo Declaration, which was released on 1 December, solemnly announced that all the territories stolen by Japan from China, including Taiwan and the Northeast, would be returned to China after the Allied Forces won the victory over Japan. In February 1945 the leaders of the United States, Great Britain and the Soviet Union gathered again, this time in Yalta, and concluded several agreements about the Far East. The Soviet Union would join the war against Japan soon after the victory over Germany with the condition that all the rights and privileges lost to Japan in the Russo-Japanese War would be returned to the Soviet Union. Actually, the United States and the Soviet Union divided their spheres of influence in China with the Great Wall as the line of demarcation: the southern part belonged to the US, while the northern part to the Soviet Union. In August 1945 the US dropped two nuclear bombs on Japan over Hiroshima and Nagasaki. On 15 August 1945, the Japanese emperor announced unconditional surrender. On 3 September 1945, General MacArthur accepted the formal surrender of the Japanese on the deck of the battleship *Missouri* in Tokyo, symbolizing the end of the Second World War.

With the end of the war, the struggle between the KMT and CPC for the right to accept the Japanese surrender intensified. In order to avoid the civil war in China and US involvement in the civil war, US President Harry S. Truman sent General George C. Marshall to China to mediate the KMT-CPC conflict. The hatred between the two parties, however, was so deep-rooted, that the mediation failed and the civil war broke out in mid-1946. In spite of US support to the KMT in the civil war, the KMT suffered disastrous setbacks, and in October 1949 the People's Republic of China was established. Chiang Kai-shek with his defeated troops fled to Taiwan.

After the end of the Second World War, Korea was liberated from Japanese rule. According to the arrangement made by the United States and the Soviet Union, Korea was divided into two parts with the thirty-eighth parallel as the demarcation line. After the CPC won, Kim Il-sung was eager to consolidate the revolution and unify the two Koreas. And on 25 June 1950, the civil war in Korea broke out. Unprepared and disadvantaged in military equipment, the South Koreans retreated in defeat. However, UN troops, led by US General Douglas MacArthur, intervened and succeeded in landing at Inchon in mid-September. The North Koreans, forced to turn from the offensive to the defensive, began to disperse. China repeatedly warned that if the UN troops crossed the thirty-eighth parallel, China would not sit idly by. But MacArthur disregarded this threat and crossed the line in October. On 26 October 1950, the Chinese 'volunteers' army crossed the Yalu River and stopped the UN offensive. After three years of difficult and intensive negotiations the four parties (North and South Korea, China and the United States) signed the armistice agreement. Soon after that the

Chinese volunteers withdrew from North Korea, while the UN troops stayed on. Since the North-South Summit of June 2000, following 50 years of stand-off, a new 'Sunshine policy' has brought a thaw to relations between the two countries. It will take time, but relations should eventually be normalized.

The civil war in China seriously influenced the US policy towards Japan. The US policy makers envisioned an Asia policy based on close cooperation with the KMT government. But the defeat of the KMT in China's civil war made this outcome impossible and at the end of 1948 US policy towards Japan underwent a major transformation that moved from destroying a hostile country into building an ally. In 1947 the so-called Peace Constitution of Japan was passed. In August 1951 the peace conference was convened in San Francisco and the United States concluded a Peace Treaty with Japan without the participation of either the Soviet Union or the People's Republic of China. At the same time the US-Japan Security Treaty was also concluded, and Japan became the United States' major ally in East Asia. The Japanese Government used that alliance to implement a policy of relying on the US for security and concentrating instead on economic recovery, which produced a remarkable result. In the 1960s and 1970s Japan became the second-largest economy in the world. The Republic of Korea, too, witnessed remarkable economic development, and some companies, like Samsung and Hyundai, gained a global reputation.

China was quite successful in its economic recovery and implementation of the first five-year plan from 1953 to 1957. Mao Zedong, however, was not satisfied with the Soviet model of development and tried to develop faster. He launched a movement called the 'great leap forward' and organized peoples' communes in the rural area. The experiment was a total failure and the country's economy was seriously hurt. This, combined with natural disasters, led to widespread famine across the country during the early 1960s, especially in rural areas.

Although China and the Soviet Union became allies in the early 1950s, differences began to emerge, and soon after Stalin's death in 1953 the differences became increasingly evident and serious; by the end there was an open rift between the two communist giants. Mao Zedong launched the so-called Great Proletarian Cultural Revolution in 1966. Lin Biao, his long-time comrade in arms, and his wife Jiang Qing took this opportunity to create chaos and disturbance across the country, and paralyzed the nation's economy. Premier Zhou Enlai, being in a very difficult situation, tried his best to save the economy and avoid splitting the country.

The deterioration of Sino-Soviet relations reached a point at the end of the 1960s when China regarded the Soviet Union as the major threat to its security. Meanwhile the United States felt that Soviet expansion posed a serious challenge to its position in the Third World. The United States also felt an urgent need to disengage from the Viet Nam War, which was consuming enormous human and material resources and causing anti-war movements across the country. In February 1972 President Nixon visited China, breaking the thick ice in bilateral relations and changing forever the Cold War geopolitical landscape. Under the influence of Nixon's visit, China and Japan established diplomatic relations in 1974. The agreement opened a new era in the history of the bilateral relations, but

did not completely overcome the historical burden inherited by the two countries.

In 1976, Zhou Enlai, Zhu De and Mao Zedong passed away, one after the other. The party secretary Hua Guofeng, with support of the veterans, was able to suppress the so-called Gang of Four and the Cultural Revolution, which lasted for ten years and brought catastrophe to the country. A number of veterans, who were overthrown during the Cultural Revolution, were now rehabilitated, including Deng Xiaoping.

With his profound strategic vision and courage, Deng Xiaoping launched reform and openness at the end of the 1970s, and normalized diplomatic relations with the United States. It was not a coincidence that the two great events took place at the same time. It meant a change of China's national goal. Before China was a revolutionary country; its goal during the 1960s and 1970s was to launch the world revolution. After the third plenary of the Eleventh Party Congress at the end of 1978, China's national goal was to develop into a modern country and to improve peoples' living standards. Diplomatically, China insisted on an independent foreign policy for peace and developing friendly relations with all countries regardless of their social system and ideology. Starting from 1979 China began the rapid economic growth that Japan had experienced, and has now become one of the economic locomotives in the region.

In 1984 China and Britain concluded the agreement on Hong Kong's return to China after difficult negotiations. On 1 July 1997, China resumed its right to govern Hong Kong. Following Hong Kong's example Macao was also handed over to China in December 1999. Both Hong Kong and Macao are special administrative zones, and the concept of 'one country, two systems' has been applied. Since their return to mainland China, stability and prosperity has been preserved in both Hong Kong and Macao with firm support from the central government.

Since the late 1970s the situation in the Taiwan Strait has been greatly relaxed. The Chinese government has pursued a policy of peaceful reunification and promoted economic, cultural and personal exchanges between the two sides of the Strait. In Taiwan, separatist forces began to develop and with establishment of the Democratic Progressive Party in 1986 the reunification of China has been seriously challenged there.

Czarist Russia collapsed in 1917, and all nationalities in Central Asia launched uprisings in the hope of eliminating ethnic discrimination and oppression. After the October Revolution, soviet regimes were established throughout the region, becoming a part of the Soviet Union. The government of the Soviet Union helped the different nationalities of the Central Asian region to develop, while they made their own contributions to the prosperity of the country. The big problem was that the Soviet Union made every republic a single-product economy so that the central government could control the economies and planning in each republic. A policy of 'Russianization' was also implemented. In spite of this, Central Asia still achieved much during the Soviet period and was basically lifted out of economic and cultural backwardness. After the disintegration of the Soviet Union in 1991 new independent countries were established in the region. But they are still new countries, and are undergoing a difficult period of social transformation.

# CHINA

China once boasted of its brilliant ancient culture and scientific achievements. But it lagged behind after the rise of the West in the seventeenth century. After the Opium War from 1840 to 1842, Chinese intelligentsia turned to the West to save the nation (the so-called Westernization Movement). Again, China was defeated in the 1894 war with Japan. The Chinese intelligentsia regarded defeat as a national shame and came to understand that the nation could not be saved without reforms. They established societies and popularized new forms of knowledge, accelerating the process of learning from Western social systems and culture. Yan Fu translated Thomas Henry Huxley's *Evolution and Ethics* and other essays, Adam Smith's *The Nature and Causes of the Wealth of Nations* and Herbert Spencer's *System of Synthetic Philosophy* into Chinese. Henry Huxley's work, in particular, served as a major shock to the Chinese community of thinkers. Influenced by those works, China's progressive intellectuals with Kang Youwei, Liang Qichao and Tan Sitong as their representatives launched the Reform Movement in 1898, but failed. However, the Qing Court assimilated some of the points raised by them in its 'New Deal' in the last decade of the dynasty.

Traditional Chinese education took Confucian classics as its major content and imperial civil service examination as its end-point. In 1901, the Qing Court shut down the imperial civil examinations and decided to establish a national administration of education in 1905. As a result, the new schools devoted to teaching modern science and technology mushroomed and a growing number of young people went to study in Japan, Europe and the United States. A new breed of intelligentsia with modern political ideas and scientific knowledge was born and new revolutionary leaders arose. Dr. Sun Yat-sen established a revolutionary organization called Tung Meng Hui and proposed the Three Principles of the People (nationalism, democracy and people's livelihood) in 1905. His followers launched the 1911 Revolution and overthrew the Qing Dynasty. This marked the end of the imperial autocratic rule that had lasted for two thousand years in China and with it the pigtails – those symbols of Qing Court service worn by Chinese men – were gone. In the meantime, such bad habits as binding women's feet were officially forbidden.

## The May Fourth Movement

Yuan Shikai, a warlord, usurped the power after the 1911 Revolution and advocated respect for Confucianism and restoration of the ancient practices. However, the new breed of intelligentsia trained in modern education was growing in number and strength and the waves of new ideas and new culture proved irresistible. Chen Duxiu and some others launched the journal of *New Youth* in 1915. The journal radically criticized the backward aspects of traditional Chinese culture, raised the slogans of democracy and science, opposed some classical Chinese writings and advocated writings and literature in the vernacular. It became the flag bearer of the new cultural movement of the time. The May Fourth Movement broke out in 1919 and the Chinese intelligentsia were again awakened in the greatest wave of emancipation of the mind in modern China. After the May Fourth Movement Western ideas flowed into China with even greater intensity. Some of the liberal intelligentsia, headed by Hu Shi, were bent on the ideas of John Dewey and Bertrand Russell, and another group of radical intellectuals, headed by Chen Duxiu, Li Dazhao and Mao Zedong, who were influenced by the Russian October Revolution, became devoted to Marxism. The latter, aided by the Communist International, established the Chinese Communist Party in 1921, while the former, criticized by both the Kuomintang and the Communists, never managed to become part of China's mainstream ideas.

The new cultural movement produced a number of historical results. Lu Xun published his story *A Madman's Diary* in 1918, the first story written in the vernacular in the history of new Chinese literature. He went on to write *Kong Yiji, Medicine* and *New Year's Sacrifices. The Authentic Biography of Ah Q*, who tried to comfort himself spiritually even though he was humiliated, became an immortal artistic model. In his later years, Lu Xun mainly devoted himself to writing essays that are critical of the social evils of the day; with penetrating insight and humour he stabbed at the heart of the old society. Like Lu Xun, Guo Moruo was another talented giant of literary versatility. His contribution was mainly in the field of the new verse. He published in 1921 his collection of verses *The Goddess*, which seeks the emancipation of personality, and sings of youth and strength with a poetic zeal that knows no bounds. It is, indeed, the epitome of the spirit of the May Fourth Movement. After Guo Moruo came such poets as Wen Yiduo, Xu Zhimo and Ai Qing.

In January 1921, Shen Yanbing (Mao Dun), Ye Shengtao and Zheng Zhenduo established the Society of Literary Study, which advocated realism. In July of the same year, Guo Moruo and Yu Dafu set up the Society of Creation, which advocated romanticism, followed by the New Moon Society founded by Wen Yiduo and Xu Zhimuo and the Yusi Society by Lu Xun, Zhou Zuoren and Lin Yutang. A proletarian literary movement came into being in the areas ruled by the Kuomintang in 1928. The Chinese League of Leftist Writers was founded in March 1930. Among the leftist writers, Mao Dun was a great novelist. His novel *Midnight*, describing the complex contradictions and struggles in Chinese society in the 1930s, is an important landmark in the history of Chinese literature. Among the non-leftist writers, Lao She's *Rickshaw* unfolds a picture of the life of the common folk in Beijing. In his novel *The Family*, Ba Jin, with heart-stirring artistic appeal, accused the traditional family of ruining the young. Other well-known writers of the period of the Republic of China were Ye Shengtao, Shen Congwen and Qian Zhongshu.

Films and drama were new forms of art introduced from the West. China shot its first feature movie in 1913. Ouyang Yuqian, Hong Shen, Cao Yu and Chen Baichen were the most important playwrights. The highest achievement was marked by Cao Yu's tragedies entitled *The Thunderstorm* and *The Sunrise*. As plays and films took hold, traditional Chinese operas developed the basis of a rich dramatic heritage, featuring such masters as Mei Lanfang, Zhou Xinfang and Cheng Yanqiu. Mei Lanfang developed the singing and performing art of the female role, forming a unique school in the Peking Opera.

Music and painting developed too during the period of the Republic of China. 'The March of the Volunteers', composed by Nie Er with Tian Han's verse, which reflected the strong will of the Chinese people for national salvation and survival, became the national anthem of the People's Republic of China after its establishment in 1949. 'The Yellow River Cantata', composed by Xian Xinghai with Guang Weiran's verse, and He Luding's 'The Song of the Guerrillas', which sang of the iron determination of the Chinese and their confidence in the final victory over the Japanese invaders, were famous songs during the period of the War of Resistance against Japanese Aggression. Wang Luobin went to Northwest China and collected or composed himself such songs as 'In That Remote Place', full of local national flavour. Xu Beihong and Liu Haisu introduced into China Western painting techniques and reformed the traditional painting. Xu Beihong was particularly good at painting horses. Liu Haisu showed his virtuosity in landscape painting, and was dubbed 'the Lion of the East'. In traditional painting, Huang Binhong and Zhang Daqian were particularly good at landscape painting, while Qi Baishi excelled in painting figures, landscapes, flowers and birds. Qi Baishi advocated 'similarity and yet non-similarity with the real objects'. With a few simple strokes, he might wonderfully bring to life a single crab or several shrimps.

After the May Fourth Movement in 1919, Marxism spread to all corners of China. Li Da's *Outlines of Sociology* (1936) expounded the basic views of dialectical materialism and historical materialism. Mao Zedong proposed integration of Marxism with revolutionary practice in China. He finished *On Practice* and *On Contradiction* in 1937 in Yan'an. They exposed the relations between man's cognition and practice and the law of the unity of opposites in the objective world. These writings became the philosophical foundation of Mao Zedong's thought.

After the outbreak of the War of Resistance against Japanese Aggression, intellectuals in large groups went to Yan'an. Mao Zedong called a forum on literature and art in 1942, urging them to serve the workers, peasants and soldiers. Mao's speech at the forum exercised great influence upon the development of modern Chinese culture. Under its impact, a number of works with entirely new styles came into being such as the opera *The White-Haired Girl*, the epic *Wang Gui and Li Xiangxiang*, and the novels *The Storms* and *The Sun Shines over Sanggan River*.

After the establishment of the Nationalist Government in Nanjing in 1927, education made some headway. Besides regular education, Huang Yanpei established the China Vocational Educational Society. Tao Xingzhi advocated learning through practice and set up work-study groups. Yan Yangchu advocated popular education and established an experimental area to try out his ideas in Dingxian, Hebei province, with some success.

The development of modern China's ideas and culture was also manifested in the development of the educational system. During the late Qing Dynasty, the school system was copied from the Japanese one, which was itself derivative of the French and German systems. In 1922, the Ministry of Education worked out its draft plan for reform of the school system, which instituted the American system of six years for elementary, three years each for junior and senior high school and four years for university education. Three kinds of schools – middle schools, normal schools and vocational schools – were established.

Missionaries were the earliest disseminators of modern natural science in China. During the Westernization Movement, Li Shanlan and some other Chinese scholars translated dozens of Western scientific and technical works. Ren Hongjuan, Yang Quan, Zhao Yuanren and Bing Zhi, Chinese students at Cornell University, launched the Chinese Society of Science in June of 1914. By January of the next year, they were publishing the journal *Science* in Shanghai. The society moved to China in 1918. Under its impact, Chinese societies of engineering, chemistry, chemical engineering, physics, biology, botany and zoology were established. The Nanjing Nationalist Government established the Academia Sinica and the Beijing Academy as the national-level institutions of research, in 1928 and 1929 respectively.

Geology was the science that registered the greatest results during this period. The most outstanding geologists were Ding Wenjiang, Weng Wenhao and Li Siguang. Ding Wenjiang made outstanding contributions through his work on the geological structures and minerals in Yunnan and Guizhou. Weng proposed for the first time that during the Jurassic and Cretaceous periods of the Mesozoic Era there appeared large-scale orogeny. Li Siguang won great honours with his studies of palaeontology, the Quaternary glaciers and the East Asian geological structures. He published in 1939 in London *Chinese Geology*, which drew wide international acclaim.

Gratifying results were also achieved in the field of biology. The Institute of Biology of the Chinese Society of Science was set up in Nanjing in 1922. Hu Xiansu did major work in gathering and classifying Chinese plant specimens. *The Atlas of Chinese Plant Life*, which he co-authored, became a classic in Chinese biology.

Such scientists as Ye Qisun, Wu Youxun, Zhou Peiyuan, Chen Jiangong, Hua Luogeng and Su Buqing made contributions either in physics or in mathematics. Zhou Peiyuan worked under the guidance of Einstein and contributed to the development of the theory of relativity and gravitation as well as the theory of the cosmos. Chen Jiangong distinguished himself in trigonometric theory of numbers, Hua Luogeng in the theory of numbers and Su Buqing in geometry. Zhu Kezhen made gratifying achievements in meteorology, Zhan Tianyou in railway engineering, Hou Depang in the manufacture of soda ash, and Mao Yisheng in bridge engineering.

Archaeological studies were first undertaken by foreign scholars. In 1906, M. A. Stein, a Briton, discovered bamboo slips dating from the Han Dynasty of 200 BC in Xinjiang. The following year a large amount of scrolls inscribed by people of the Tang Dynasty (AD 618–907) were found in the Mogao Grottoes of Dunhuang. Special studies were undertaken on the basis of the two discoveries. Johan Gunnar Andersson, a Swede and consultant to the Beijing Institute of Geology, discovered the painted-pottery culture of the New Stone Age in Yangshao Village, Henan Province in 1921. Pei Wenzhong discovered in 1929 the skeleton of the apeman Beijing Man, who lived 400,000 or 500,000 years ago, in Zhoukoudian, Beijing. In 1928, large-scale work was launched to excavate the ruins of the Shang Dynasty (sixteenth to eleventh century BC) in Anyang of Henan, and large numbers of inscribed bones and tortoise shells of the Shang Dynasty had been found by 1937. Wang Guowei, Dong Zuobing and Guo Moruo studied ancient Chinese history as interpreted through these inscriptions, with great success.

## The People's Republic of China

The founding of the People's Republic of China in October of 1949 marked the beginning of an entirely new stage in Chinese history. Science, education and culture made initial headway, however, there were many twists and turns. There were repeated movements of ideological and cultural repudiation in the 1950s. Mao Zedong in 1951 wrote a *People's Daily* editorial criticizing *The Story of Wuxun*, which describes an educator who raised money by begging. In 1954, he supported two young critics of Yu Pingbo, a specialist of the classic Chinese novel *The Dream of the Red Mansion*, which finally initiated mass criticism of Hu Shi's theory. In 1955, the criticism of Hu Feng's ideas on art and literature escalated and members of the so-called Hu Feng counter-revolutionary clique were arrested. In February of 1957, Mao Zedong put forth the idea of letting 'a hundred flowers bloom, a hundred schools of thought contend', which was a correct policy to let art and science thrive. However, it was virtually given up after the anti-rightist struggle in the same year. After 1962, criticism expanded from art and literature to the fields of philosophy, economics, historical study and educational science. In 1966, the so-called Cultural Revolution was launched with the criticism of Wu Han's *Hai Rui Dismissed from Office*. The extreme idea of negating and sweeping everything away caught fire. Most of the schools suspended classes and the majority of cultural establishments were paralyzed; many important people were branded as 'demons and devils'.

Not long after the founding of the People's Republic, the government carried out a campaign to reform the educational system and education made headway on this basis. However, it was completely destroyed during the Cultural Revolution. After the overthrow of the 'Gang of Four', educational development returned to normal. The Chinese government decided in 1977 to restore the university entrance examination. A degree system was instituted in 1981. The Law on Compulsory Education was promulgated in 1986, calling for implementing the nine-year compulsory education program in a planned way. As the government was running the world's biggest education system, it found itself seriously short of funds. More recently, with a view to helping children who drop out of school in poverty-stricken areas, 'Project Hope' has been launched to rally society at large to support education.

Science has developed considerably in the People's Republic. The Chinese Academy of Sciences, with 22 institutes, was established in 1949. Since 1985, thanks to Deng Xiaoping's idea of 'science and technology as the primary productive force', the government has made a series of decisions to reform its scientific and technological management system. Now, China has set up a fairly comprehensive scientific and technological system and Chinese scientists have achieved major successes in theoretical mathematics, high-energy physics, structural chemistry, Earth science and biology. In the meantime, the oil, iron, steel, electronics, nuclear and space industries have grown rapidly.

China decided to build a nuclear industry in 1955. Such outstanding scientists as Qian Sanqiang, Zhao Zhongyao, Wang Ganchang and Deng Jiaxian contributed their talents to the cause. China successfully exploded its first atomic bomb on 16 October 1964 and its first hydrogen bomb on 17 June 1967. With great attention to the peaceful uses of nuclear energy, the Chinese government has of late built nuclear power plants in Zhejiang and Guangdong.

In 1963, China pioneered microsurgery and has since remained in the front ranks. The following year, Chinese scientists in their earliest efforts artificially synthesized bovine insulin and then yeast alanine transferred ribonucleotide. In 1983, China made a super computer capable of calculating well over 100 million times per second.

China launched its man-made Earth satellite on 24 April 1970 and its long-distance carrier rocket in May of 1980. And the new-type rocket Chang Zheng No. 3A, which can carry up to 2.5 tons was, launched in 1994. By August of 1994, China had launched a total of 42 multi-purpose man-made satellites. It has attained advanced levels in satellite return, multi-satellite rocket carriers and satellite surveying and control. In 1994, Chinese scientists could claim to be in the front ranks in nano-scale technology.

Science and technology have played a decisive role in China's economic growth. Before its founding in 1949, China only produced 120,000 tons of crude oil. Since 1959, based on new theories, a number of oilfields such as Daqing, Shengli and Dagang were discovered with an annual oil output of 146 million tons in 1994. From an oil-poor nation, China has become a major oil producer.

With full attention to natural scientific research, the Chinese government has established the national natural science funds and national natural science prize, the national prize for scientific and technological advancement as well as the national prize for scientific and technological inventions. The Chinese Academy of Engineering was established in June of 1994. The He Liang-He Li Fund prizes were conferred on Qian Xuesen, Huang Jiqing, Wang Ganchang and Wang Daheng in Beijing in January 1995. Qian Xuesen has done pioneering work in aerodynamics, aviation engineering, jet propulsion, the theory of engineering control and physico-mechanics, and played a tremendous role in the development of China's space industry. Huang Jiqing is a pioneer in geology in the People's Republic. His tectonic theory has guided China to major breakthroughs and discoveries of oil reserves in the land-facies sedimentation. Wang Ganchang is a pioneer and founder of Chinese nuclear physics. Wang Daheng has made outstanding contributions to the establishment and development of optics, optical engineering, optical precision machinery, space optics, laser science and metrological science. Among the 20 scientists who won the Fund prizes, Wang Yuan is one of China's leading mathematicians in the theory of numbers; Chen Jingrun is well-known for his proof of the Goldbach conjecture; Wang Zhenyi is a leading medical scientist in the treatment of leukaemia and a winner of the Catherine Prize – one of the major international awards in cancer research; Wu Mengchao is one of China's founding fathers of liver surgery; and Yuan Longping is the 'father of crossbred paddy rice' as he is called in the international scientific community.

The open reform policy in the current stage of development has provided both the social sciences and humanities with very good development opportunities. The Chinese Academy of Social Sciences was established in 1977 on the basis of the previous Department of Philosophy and Social Sciences of the Chinese Academy of Sciences. In 1978, the Chinese government decided to compile *The Chinese Encyclopedia*. The publication of all 74 volumes of

the *Encyclopedia* with 80,000 entries in 69 disciplines of knowledge totalling 125 million Chinese characters was completed in 1993. It is the biggest publication in the last few years. Other important publications include *The Complete Works of Chinese Art*; *The Atlas of Chinese Historical Maps*; *The Complete Works of Studies on the Characters Inscribed on Tortoise Shells*; *The Modern China Series*, etc.

Outstanding work has been done in archaeological excavations and protection of cultural relics. Excavations have been made in Hemudu (7000–5000 BC), the burial place of the terracotta warrior and horse figurines in the Mausoleum of Qin Shi Huang, the tombs of the Han Dynasty in Mancheng (second century BC) and Mawangdui, the Tomb of the King of Nanyue (second century BC). The fossils of the Lantian and Yuanmou apemen, gold-and-jade-inlaid garments, sets of ancient musical bells, paintings and calligraphic works made on silk, and bamboo slips inscribed with characters have been unearthed. Since 1961, the Chinese government has declared 242 places of historical or cultural interest under state protection. Beijing, Xi'an and some other cities are listed as famous cities of historical and cultural interest. The Forbidden City, the Great Wall, Zhoukoudian, the Mausoleum of Qin Shi Huang and the Dunhuang Grottoes have been inscribed on the UNESCO World Heritage List.

Such writers as Guo Moruo, Lao She, Tian Han, Ba Jin, Zhao Shuli and Yao Xueyin, who had already made a name for themselves, maintained their creativity after 1949. The play *Teahouse*, written by Lao She, reflected the social changes during the period of the Republic of China. Such novels as *Red Banner* and *Red Crag* try to give an in-depth study of large-scale artistic and historic works. He Jingzhi, Guo Xiaochuan and Wen Jie made their own experiments in the composition of new poetry.

During the Cultural Revolution, all withered except for modern Beijing Opera plays such as *Sha Jia Bang*, *Red Lantern* and *Seizure of Wei Hu Mountain* and the ballet *Red Women's Detachment* and four other so-called model plays. After the Cultural Revolution the 'scar literature' that describes the storm and stress of that tragic period became fashionable. Ever since all kinds of schools of creative art with different styles have thrived in a pluralistic structure.

The People's Republic has trained a large group of talented musicians. Fu Cong and many other pianists and vocalists have won international prizes. The violin concerto about Liang Shanbo and Zhu Yingtai describes a tragic love story with moving rhythms. The instrumental ensemble 'The Moon in Spring Water', adapted from the work of the same title by Hua Yanjun, a folk artist, moves the audience in the same way as if they were listening to a tragic story. *Rain of Flowers on the Silk Road* and *Fish Beauty* are, respectively, representative works of China's national dance and ballet. Chinese traditional acrobatics, after revision and improvement, have won many international laurels.

Though in use for thousands of years, Chinese characters are highly complex. The Chinese Character Reform Committee was established in 1954. It promulgated the general list of Chinese characters with simplified strokes in 1964. In the meantime, the Chinese government decided to popularize Mandarin Chinese, based on the Beijing dialect, in 1958. It announced the draft plan for the pinyin (Latinized on the basis of the pronunciation of the Chinese words) of the Chinese language in 1958 as a complementary

means to studying Chinese. At present, Mandarin Chinese has become the principal language of communication across the country. Thanks to the birth of a series of computer input modes such as the five-stroke system initiated in 1983, Chinese has been successfully applied in computer processing.

China is a country with more than fifty nationalities. The Chinese government practices national autonomy and freedom in religious belief. Chinese writers collected and collated in a planned way folk works handed down orally among the minority ethnic groups. The Mongolian epic *Jiange'er*, which speaks of brotherhood, marriage and war, has 100,000 lines of verse and is the literary treasure the Mongolian people. The Tibetan epic *The Story of the King of Gesa'er* portrays the heroic image of King Gesa'er and expresses the wish of the Tibetan people for political stability, prosperity and improved working conditions. The Chinese government has also devised written languages for such nationalities as Yi, Dong, Lahu, Jingpo, Zhuang, Bouyei (Puyi), Li, Xibo and Wa, which used to have only oral languages.

The level of sports practiced during the period of the Republic of China was very low. But after 1949, thanks to hard effort, it has risen. China has stayed at the top of table tennis honours for a long time. The Chinese women's volleyball team won the championships five consecutive times in major world championships in the 1980s. The Chinese men's gymnasts team won the world group championships several times. China re-joined the Olympic family and its sharpshooter Xu Haifeng scored its first-ever Olympic gold medal at the 1984 Los Angeles Olympic Games. In the last few years, the Chinese have scored a flurry of honours in weightlifting, diving, women's basketball, women's swimming and women's intermediate and long-distance running. In 1993, the Chinese won 103 world championships, and 38 athletes and 7 teams broke the world records in 57 events on 124 occasions. In 1994, they won 79 world championships and broke 41 world records. At the Hiroshima Asian Games of the same year, as China's gold medal tally was far more than the Republic of Korea and Japan, China became Asia's No. 1 sports power. However, China's track and field and men's football still lag behind but are catching up fast.

China is the country with the largest population in the world. In 1953, the Chinese government endorsed 'Rules for Contraception and Artificial Abortion'. It made an explicit call for birth control. Ma Yinchu, the President of Beijing University during that time, published his *New Theory on Population* in July of 1957, proposing control on the population and improving its quality. Unfortunately, his ideas were mistakenly criticized. Since the 1970s, the Chinese government has worked hard to control the population increase, and the birth rate dropped from 33.43 per thousand in 1970 to 18.09 per thousand in 1993. In the past 20 years or so, China has had 300 million fewer babies born. However, as the base number of population was too big, Chinese population hit the 1.2 billion mark in February of 1995.

Traditional Chinese medicine is one of China's major contributions to humankind. The Chinese government promotes the integration of Western medicine with traditional Chinese medicine and the collation of traditional Chinese medical heritage with scientific methods. The ancient art of medical treatment – acupuncture and deep

breathing exercises – has been rejuvenated, and acupunctural anaesthesia has been applied. In the last few years, Chinese medical scientists have been trying to use traditional Chinese medicine to treat such deadly diseases as cancer and AIDS. Many of these traditional ingredients have now been validated.

The tremendous development of science and culture after 1949 is clearly reflected in the following figures. By the end of 1994, there were 20,516 scientific research institutes, 1.53 million scientists and engineers, 1.88 million physicians and surgeons; 128,000 postgraduates, 2.8 million university students, 58.26 million middle school and polytechnic school students, 130 million primary school pupils. China boasted 2,681 performing art troupes, 2,875 cultural centres, 2,579 public libraries, 1,140 museums, 3,585 archives, 1,108 radio stations, 764 TV stations. Radio broadcast and TV transmission covered more than 80 per cent of the population. China produced 148 movies, printed 18.67 billion newspapers and 2.25 billion journals and published 5.93 billion volumes of books in the same year (excluding Taiwan, Hong Kong and Macao). Nevertheless, China is a big nation that had been poverty-stricken for a long time. It is still a developing nation with difficulties and problems of all kinds. China ranked 65th among 130 nations for life expectancy in the UNDP's Human Development Index in 1994. At the same time China had 180 million illiterates over 15 years of age and the national average time in school was only 5.4 years. By 2002, the UNDP's *Human Development Report* showed the following improvements: Life expectancy at birth had risen to 70.9 years; adult literacy ages 15 and above had risen to 90.9 per cent, and combined gross enrolment for primary, secondary and tertiary schools had risen to 68 per cent.

## Taiwan

Defeated in the Civil War, Chiang Kai-shek fled to Taiwan in 1949. After an initial period of chaos, Taiwan's economy began to take off from 1964 to 1973 and science and culture correspondingly made headway.

The Taiwan authorities designated 1954 as the year of science. They established a Science and Education Committee in July of that year that worked out the 'Long-Term Program for the Development of Science' and set up the Long-Term Science Development Committee in 1959. The Taiwan Academia Sinica got financial support from the United States and established centres of mathematics, physics, chemistry, biology and engineering science in 1964. The Science Promotion Committee headed by Wu Dayou was established in 1967. The Taiwan authorities expanded the Science Development Committee and set up the National Science Committee of the Executive Yuan in 1969. Ever since, the funds for scientific and technical research and the number of people engaged in scientific research have rapidly increased. The funds appropriated to scientific and technical research rose nearly five-fold and the number of people engaged in scientific research shot up by 100 per cent in 1981 as compared with 1978. Nevertheless, scientific research in Taiwan is mostly in applied science, and basic research receives much less attention.

Not long after he went to Taiwan, Chiang Kai-shek promoted the slogan of 'education first, teachers first'. Since

1968, the Taiwan authorities have mandated nine years of compulsory education. They promulgated the National Education Law in 1979 and Rules for Compulsory Education in 1982, stipulating that nationals from 6 to 15 years of age must go to school and that those who fail to do so will be fined. In 1982, the rate of attendance of junior high school pupils reached 98 per cent. To develop vocational and technical education, Taiwan set up the Industrial and Technical College in 1974, enrolling graduates from senior vocational schools. Their aim is to link up the vocational schools, polytechnic schools and technical colleges with education and employment.

Taiwan's film industry has made rapid progress. Its output of feature films recently ranked third in the world, coming after Japan and India. However, though the output was high, the quality was variable. There is a new wave of ideas almost every eight or ten years in Taiwan's literature as the pendulum swings between traditional native literature and modernism. A good representative of the former is Chen Yingzhen, and Bai Xianyong is an important modernist writer.

## JAPAN

This section is divided into two periods: the interwar period and postwar development.

The Chinese were earlier than the Japanese in recognizing the superiority of Western astronomy in the seventeenth century and the strength of foreign military technology in the mid-nineteenth century. But the Japanese excelled in recognizing the importance of the industrial infrastructure behind modern military technology and the significance of Western political institutions such as imperialism. In the process of catching-up in military technology at the turn of the century, Japan overstepped the mark and launched into imperial expansion by invading neighbouring Asian countries.

### The interwar years

The First World War did not yield any significant breakthroughs for Japanese science and culture. The war was largely a European matter, but Japan nevertheless took advantage of it. Because of the lack of Western competitors in Asian markets during the war, Japan enjoyed a veritable economic boom.

Ideologically, however, like everywhere else in the world, Japanese intellectuals and scientists were fascinated by the success of the Soviet Revolution in 1917. The periods that followed the First and Second World Wars are similar in being characterized by waves of democratization, although the political contexts of these periods are quite different. The former is called Taisho democracy (after the name of the era), whereas the latter is dubbed 'sengo' (post-war) democracy. As the name suggests, 'the war' for the Japanese means the Second World War, not the First.

The post-First World War economic boom mentioned above was accompanied by the expansion of higher education. Up until that time, the government bestowed university status only on governmental institutions where faculty and students were, according to the constitution, supposed to serve the national interest. Parallel to the rise

of the Taisho democracy and the privatization trend were government measures in 1914 aimed at reforming the university system. These were put into effect in 1918, when an act was issued to confer university status on private as well as prefectural institutions, and what is more, research was added to the official function of universities in addition to education. As a result, a number of higher education institutions were established after the First World War. However, when the students who had been admitted into the expanded higher education system graduated, they were greeted by economic depression in 1928 and the following years. Unemployment was high.

It was, however, thanks to lessons learnt from the First World War that scientific research, particularly in the field of chemistry, was for the first time recognized as an indispensable component of a modern nation-state. Because supplies had been disrupted by the outbreak of war in Europe, Japanese industries made serious attempts at developing import-substitution technology. Reverse engineering was the major path they followed. All of the above encouraged the establishment of both public and private research institutes.

Scientists had previously been busy establishing university education, part of the institution-building in the early phase of modernization during the Meiji period. The post-First World War generations were freed from such tasks and sought, instead, to challenge the research frontier being forged in Europe. The Japanese scientific community had come of age and was able to produce internationally oriented academic scientists.

Internationalism prevailed in the scientific community, with luminaries such as Albert Einstein, Margaret Sanger, and H. G. Wells invited to visit Japan and enthusiastically welcomed by Japanese intellectuals and scientists.

Public universities were the most important, if not the only, windows on the West, through which new trends in science and culture entered Japan. Universities enjoyed high status compared to public and private laboratories and institutions.

University-affiliated research institutes came into existence right after the First World War. The first such institute was the Aeronautical Research Institute, affiliated with Tokyo Imperial University, which was inaugurated in 1918. This was followed by the Tokyo Astronomical Observatory, also of Tokyo Imperial University (1921), the Metals Research Institute of Tohoku Imperial University (1922) and others. In these institutes, professors and assistant professors were all appointed to engage solely in research work, while enjoying life-long tenure.

After half a century spent transferring Western culture, science and technology, first from the West to the Japanese public sector and then from public to the private sector, the private sector had been placed on a strong footing.

Let us take a typical example of Japanese private science development in the Toyoda family. Sakichi Toyoda, the founder of the Toyota Corporation, was a local carpenter who took advantage of the domestic patent system and imitated imported machinery. He established the Toyoda Loom Works in 1906. It was his son Kiichiro, a graduate of the Engineering College of Tokyo Imperial University, who started a systematic approach to research and promoted the family's entry into the automotive industry in the late 1930s.

In the absence of a rich domestic market, the Japanese car industry initially had to depend on military subsidies.

Rather than aim at the production of passenger cars, the goal was to build up domestic capability in the production of trucks and tanks, both essential to national security. The development of Japanese aircraft technology was equally dependent upon military support throughout the interwar period. Thus, privatization went half-way, largely dependent on military sponsorship and government encouragement.

There emerged, however, another line of scientific and technological development in the post-First World War period. Following developments elsewhere during the war, a growing number of businessmen, academics and bureaucrats became convinced that Japan needed a large, centralized, research establishment. They tried to copy the recently established German Kaiser Wilhelm Gesellschaft (established in 1911) and founded Rikagaku Kenkyusho (the Institute of Physical and Chemical Research, abbreviated as Riken) in 1917. In 1937, they promoted *kagakushugi kogyo* (scientific industry) rather than 'capitalistic industry', reflecting the technocratic stance that they subscribed to.

The idea of a science uncontaminated by capitalism was not translated directly into any actual movement of scientists, as the system was so radically different from elsewhere. Only after the big 1923 Tokyo Earthquake did a student-led movement aimed at relief for the poor emerge among medical students at Tokyo Imperial University. The students were suspected by police of being political dissidents.

Senji Yamamoto, a pioneering leftist biologist, had been active in claiming laboratory democracy and advocated 'proletariat science'. He participated in the labour movement and popularized Margaret Sanger's ideas of birth control. He was assassinated by a right-wing extremist in 1929.

From 1930, government suppression of left-wing thought became so severe that many scientists turned to the history of science, and philosophical discussions on science and technology. The historical materialism advocated by Boris Hessen at the Second International Conference of the History of Science in 1931 was enthusiastically studied and two translated versions of his work appeared in Japan.

Kinnosuke Ogura and other scientists and philosophers formed the Yuibutsuron Kenkyukai (Society for the Study of Materialism) in 1932 and issued their monthly *Yuibutsuron Kenkyu*. Most of its members were arrested and imprisoned. In 1941, the year that Pearl Harbor was bombed, the History of Science Society of Japan was organized, providing shelter for many leftist and liberal scientists who joined it. By replacing the words 'Marxism' or 'materialism' with the word 'science', they were easily able to avoid official censorship.

In 1931, the government tried to cope with the economic environment by shortening university education and by professionalizing the higher education sector. Such measures were doomed to fail, given the fierce opposition of the university establishment. In that same year, the Manchurian Incident occurred. In the subsequent economic boom created by military production, the need for rationalization of the tertiary education sector was no longer necessary. Thus, Japan's recovery from the Depression came earlier than in the USA under the New Deal.

It was against the backdrop of a military oriented economic boom that the Japan Society for Promotion of Science (JSPS) was established towards the end of 1932.

The JSPS encouraged group rather than individual research, and also invited not only university scientists but also private, government and military scientists to cooperate in team projects.

During the war, Japan was isolated from the Western world, its major source of scientific and cultural information. Only a very limited number of scientific journals were imported by submarine from Nazi Germany.

Ironically, however, it was a happy period for Japanese scientists and engineers who, for the first time, were recognized as being indispensable to the war effort. It was also a time during which Japanese scientists became more independent of Western influence.

Japanese efforts were spearheaded by the establishment of a new Technology Agency aimed at enhancing state control of science and technology. Unfortunately for the Agency, other governmental departments did not cooperate and their attempts to harness science for the war effort were lacklustre. Science students were exempt from conscription during the war. The ratio of humanities majors at higher schools to science majors was normally 6:4, however, this ratio was effectively reversed by government policy, which sought to increase the number of scientists and technologists. By the end of the war in 1945, humanities majors had practically disappeared, having been conscripted prior to graduation.

During the first 30 years of this century a new culture based on popular society took shape. This was exemplified by the popularity of the modern novel as the favorite literary form. Toson Shimazaki wrote *The Broken Commandment*, which described the self-awakening of lower-class youth in Japan. Katai Tayama's novel entitled *A Cotton Quilt* vividly depicted a middle-aged intellectual's longing for a schoolgirl. Their works reflected the thoughts of Japan's new social classes in early years of the century.

There was a sharp struggle between the different approaches to culture. One ideological stream was Minbonshugi (Japanese Democracy), and Tatsukichi Minobe, a Professor at Tokyo Imperial University, was its major standard-bearer. This trend propelled the popular movement for democracy and freedom. Another trend sided with modern international views, which advocated cutting down on armaments and initiating peace, for the sake of international cooperation with Europe and America.

## The postwar period

Postwar reform in Japan was wide in scope. Land Reform, the most important, affected the very powerful class of peasant landowners (89.1 per cent of peasants). Secondly, workers' power was rising. By 1960 ten million workers participated in various kinds of trade unions and workers' movements on a daily basis. Under pressure of the left wing and community of nations, Japan promulgated a new Constitution in 1946, clearly stipulating that sovereignty is formally vested in the people. Article 9 of the Constitution says that Japan should relinquish all armed forces and abstain from war. On the other hand, the system included the existence of political parties and an executive Cabinet. In 1955, a number of conservatives joined the Liberal Democratic Party. For the next 38 years the LDP (Liberal Democratic Party), having most seats in the House of Representatives, was continually in office. The Socialist and Communist Parties and other left-wing parties were powerful in the opposition because they united the workers and masses in Japan's cities. A desire for peace was the prevailing trend, and Marxism, existentialism and American philosophy were all warmly welcomed by the Japanese.

The post-First World War phenomena of Taisho democracy was revived after the Second World War and labelled 'sengo' democracy. Despite apparent similarities, the two democratic movements were radically different. The former was primarily an intellectual exercise imported from the West, whereas the latter was adopted according to the American occupation policy. Even though imposed by the occupation directives, democracy was welcomed wholeheartedly by the Japanese, who had bitter memories of the coercive, ultra-nationalistic ideologies of the wartime and military governments.

In January 1946, Japanese intellectuals and scientists created the Federation of Democratic Scientists (Minka) in the hope of rebuilding a democratic Japan through the creation and dissemination of science. Though organized by prewar Marxists, membership in the new organization was extended to all who were active in every field of learning, including academic scientists, practicing engineers and medical doctors. Their common enemy was wartime militarism, which was viewed as having impeded the development of science and democracy. Their slogan resembled that of the Chinese May Fourth Movement in 1919, where science and democracy were promoted as part of a political campaign to combat feudalistic Confucian traditions.

The occupation forces sought to eradicate the militaristic elements of Japanese society and encourage research and development primarily for economic recovery. They were less enthusiastic about promoting basic science, which they considered as being too extravagant in a country fighting off mass-starvation.

After the occupation, the Japanese switched from a wartime survival strategy based on military technology to a more market-oriented, commercial one. Nevertheless, the same 'progress or perish' drive has characterized Japanese industry even to this day.

Those in Asia who had survived wartime Japanese invasion watched fearfully lest there be a revival of Japanese expansionism. But Japanese people had also been victims of harsh wartime suppression of thought and expression. Those who had suffered during the war became steadfastly pacifist, and it was they, in the final analysis, who were responsible for transforming military-oriented science and industry into economy-oriented progress.

After the end of the war, Japanese academic science was still respected internationally, as it was possible to carry out research equipped only with 'pencil and paper'. This was exemplified by the theoretical work of Hideki Yukawa, who was the first Japanese scientist to be awarded the Nobel Prize in 1949. Meanwhile, corporate science was undergoing a crisis due to economic stagnation, but this situation was reversed as economic recovery advanced. Today, the private sector contributes more than 80 per cent of total Japanese R&D expenditure.

Although the centre of scientific activity shifted from Germany to the USA in the 1920s and 1930s, the Japanese scientific community adhered to the old pattern of sending students to Germany as in prewar days. During the

occupation years, however, the trend changed radically and almost all went to the USA, taking advantage of Fulbright programmes and others scholarships to pay their way. Upon their return, they established new paradigms and became the leaders in their respective disciplines.

In the 1970s, the situation was reversed after the high economic growth of the 1960s. Americans no longer had the funds to hire Japanese academics, constrained by severe budget cuts implemented around 1968. On the other hand, the Japanese industrial sector began sending their employees to American laboratories where professors had research contracts with Japanese corporations. In the meantime, Korean and Taiwanese scientists in the USA were being lured back home by their home governments' policies aimed at reversing the brain drain.

In the 1970s, there were scientist-critics who quit their trade and became 'ecologists' of a kind, berating science for its detrimental impact on society. A literary critic, Junzo Karaki wrote a famous 'Memorandum on the Social Responsibility of Scientists' which questioned the way of thinking of Hideki Yukawa, Japan's Nobel laureate in physics, who had been active in urging the abolition of nuclear bombs. He suggested that he should direct his attention more to matters concerning his professional occupation rather that focusing on the more basic value of human existence.

It was a time when Western historians of science started to look upon traditional East Asian science as an 'alternative science'. In the late 1960s, China proclaimed a new research method in science involving mass participation of the type espoused by 'barefoot doctors'. This movement was interpreted by Japanese radical intellectuals as being an experiment in anti-professionalism, and viewed as providing timely lessons for the overspecialized science profession found in advanced countries. For developing countries, it suggested a more realistically attainable goal of appropriate technology.

Progressivism was seriously challenged by the campus protests of the late 1960s, which hit most industrialized countries in the West. Japan was no exception, even though political causes like the Viet Nam War were missing and economic growth was at its height.

The student protests and university reforms of 1968–70 and the environment and ecology movements in 1972–73 had an impact on science and culture; however book publication statistics show that the oil crisis, which occurred in the fall of 1973, had a greater influence on ordinary citizens, encouraging a change in attitude towards the use of natural resources and energy. It was not student campus riots so much as the anti-pollution movement that had the greatest impact on industry. This, combined with the oil shock of 1973, encouraged the government, particularly MITI (Ministry of International Trade and Industry), to shift the focus of industrial policy from 'heavy, thick, long and large' kinds of products manufactured by energy-intensive heavy and chemical industries to 'light, thin, short and small' products manufactured by knowledge-intensive industries such as microelectronics and biotechnology. In spite of the transformation of Japan's industrial structure and the trauma of two oil shocks, Japanese industry as a whole continued to develop into the 1980s.

In the 1980s, it was widely noted that a special feature of Japanese culture has been its high technology. The Science and Technology Agency promoted the slogan *kagakugijutsu*

*rikkoku* ('nation building by science and technology', a type of technonationalism). The words have the nationalistic connotation of building up Japan's own creative technology as a bargaining tool against the USA. Neither European nor Third World countries featured in the Japanese range of vision.

Since 1980, the US has recognized Japan as a technological competitor and the FBI started investigating Japanese infringements of American intellectual property rights. The IBM industrial espionage incident in 1982 involving the arrest of Japanese company personnel by the FBI shocked the world. The Japanese, mindful of a hostile US attitude, adopted the new slogan of 'internationalization' instead of 'technonationalism'. This change of slogan implied a general switch in international strategy from competition to cooperation.

The change in slogan was officially recognized by the Science and Technology Council in 1984. Corporations differed in how they incorporated internationalization into company policy, but most microelectronics companies like NEC, Toshiba and Mitsubishi adopted appropriate measures in the mid-1980s in order to avoid headlong conflict with the USA. Internationalization also served as a way of familiarizing employees with foreigners who were given positions alongside them at the workplace.

Some companies acquired costly research institutes in the USA, in an attempt to promote synergies with American enterprises. The result has been that R&D is less and less subject to the control of the Japanese government.

After the Second World War, along with Japan's economic recovery and rapid growth, the country has stepped onto the stage of international culture since the 1960s.

In late 1940s and 1950s, many Japanese people became introspective and self-critical about their responsibility for the war: they advocated 'a hundred million people repentance'. A whole school of literature emerged whose main subject was to dissect the reasons and the horrors of the war. With the second and third generations the trend was towards pacifism. Yasushi Inoue wrote a number of works, such as *The Top of Building in Tenbyo Period* and *Dunhuang*, praising friendship between the peoples of Japan and China.

After the 1950s and with the economy reviving, Japan adopted a more popular society. The way of life also changed under the influence the American culture. All kinds of popular media flourished. Newspapers like *Asahi Shinbun*, *Mainichi Shinbun* and *Yomiuri Shinbun* were so popular that their combined circulations reached sixty million copies. Broadcasting, TV and magazines became an important part of people's daily life. Popular writers such as Seicho Matsumoto, Seiichi Morimuro, Jiro Akagawa and Shinichi Hoshi sold millions of their books. They described common Japanese joy, anger, grief and happiness; or they recounted dark transactions between political and financial circles. Adult fairy tales, mysteries and science fiction were equally important trends in popular culture.

Japanese culture also went out to the world. Traditional Judo was successfully placed on the international Olympic Games' events. Kara-Okay, better known in the West as karaoke, a kind of self-entertainment, was invented and introduced everywhere in the world with the aid of electronically recorded music. Yasunari Kawabata and Kenzaburo Oe were awarded Nobel Prizes for literature, the former due to his depiction of Japanese traditional beauty, and the latter due to his humanism.

After the 1970s, there was a return to tradition in Japanese culture. Traditional opera again became very much appreciated. Some famous Kabuki actors and actresses were given the title of National Treasure on Earth. The major reason for this trend was Japan's role as an economic giant, rising nationalism and emphasis on Japanese cultural specificity.

## Conclusion

The most remarkable transformations during the period are summarized below. The notion of progress for survival was the major driving force for the Japanese, during both the prewar period of arms build-up, and in the postwar period of economic recovery. This zeal was also responsible, however, for overseas colonial expansion in the prewar days and contributed to the environmental pollution which Japanese society had to face in the postwar period. High technology was and has been the most prominent feature of postwar Japanese culture, occurring in the absence of any particularly serious religious, class or race conflicts, and at a time when ultra-nationalism had been largely wiped out. Economic development was mostly entrusted to the private sector, with some official guidance during the early days of technology transfer. In this way, lessons were learnt from Japan's prewar experience but at the high cost of defeat at the end of the Second World War.

## THE KOREAN PENINSULA

By the end of nineteenth century, with the adoption of an open port policy, science and technology were introduced from the Western world into the Korean Peninsula.

In 1898 a joint venture was established by the Korean royal family between Seoul Electric Company (Hansong) and an American named Colbran. As a result, the first streetcar showed up in Seoul. In 1900, electric lights and modern lighting installations were also introduced in Seoul. In the early twentieth century, two railway lines, Seoul to Pusan and Seoul to Sinuiju lines, were constructed by the Japanese.

Around 1904 and 1905, Korea was forced to accept the so-called protection of Japan, which initiated the bourgeois national independence movement and the patriotic enlightenment movement. Though distinctive from each other, the two movements jointly formed the dominant political and cultural concern. Educational aspects of this new cultural movement were taken over by The New People's Association, along with other enlightened organizations. Before 1910, when Japan finally annexed the peninsula, 3,000 modern private schools had been established in Korea. Feudal culture and thought were disappearing, and modern science, history, geography, law and mathematics were successfully introduced. Such names as Auguste Comte, Hegel, Bacon and other modern philosophers' theories were widely known.

The New Cultural Movement aimed at arousing people's consciousness and attacking the Japanese invaders. Articles written by two forerunners of the movement, Chang Chi-yon and Huang Hyun, attacked Japanese annexation and ignited the wrath of the Korean people. Their articles were reprinted in various international newspapers.

After the annexation Japanese administrators issued a so-called education law, and schools were now under their strict control. Koreans were forced to adopt Japanese names. As a result, Korean students were being kept in ignorance of their own culture. Between 1910 and 1922, the number of private schools in Korea dropped from 2,000 to 600.

In 1919, the March First National Independence Movement along with the declaration of independence issued in Tokyo by 33 independence advocators encouraged the Korean people to resist Japan and liberate their own country. After this movement, Marxism and Leninism were introduced to Korea. Marxist study groups, like the Proletariat Federation, the Reading Club and the Social Science Research Society, appeared in Seoul, Pyongyang, Pusan, Daegu, Hamhung, Wonsan, Inchon and other industrial cities as well as some rural areas. Such magazines as *New Life*, *The Light of Korea* were published in public and propagated Marxism and Leninism. Various resistance groups, political parties and organizations were founded, whose aim was to expel the Japanese invaders and gain independence.

In the early twentieth century, Korean science and technology saw little progress, though *The Korean Science History* was published by Hong Yi-sup, and bridge construction and ship-building started to develop. In 1917 the schools for specialized scientific and technological training appeared. However, by the end of 1944, there were only 266 graduates, and by the end of the Second World War, only 700 graduates in total from the Kyongsong Industrial School, the Kyongsong Mining School and the Daedong Industrial School.

In 1931, the establishment of the Society of Korean Language Research initiated the reform of Korean characters. This led to the Society producing a *Korean Dictionary* and *Unified Principle of the Orthography of the Korean Alphabet*. These were not only academic achievements, but also meant the enlightenment of the academic circle. In 1933 the new spelling system issued by the Society had spread throughout the country.

The seeds of the new literature planted in the early twentieth century began to bloom about 20 years later. The New Trend School (also called Puro) started in 1923, and was soon well established. The Korean Proletariat Artists Federation (KAPF), set up in 1925, promoted Puro literature. Meanwhile, the anti-Japanese literature was also flourishing. Such poets as Han Yong-un, Yi Yuk-sa and the writers Yi Sang-hwa, Sim Hun, and Hyon Chin-gon were representative figures of the period. Other masterpieces include *Your Reticence*, written by Han Yong-un, *Some Day*, by Sim Hun, and *Poor Wife* by Hyon Chin-gon.

### The Democratic People's Republic of Korea

After the Second World War, the Korean Peninsula was split into North and South and in 1948 separate governments were established for each. The war between the two parts, which lasted from 1950 to 1953, was devastating for the entire peninsula.

For half a century, the two parts have offered contrasting political systems. The North respects a strict socialist system, while the South has adopted parliamentarianism.

The Juche Idea, the theoretical basis guiding the establishment of the Democratic People's Republic of

Korea (DPRK), and the Korean Labor Party focus on such principles as initiative in one's own political views, an independent economy and self-reliance.

The DPRK pays great attention to education. Soon after the country's founding, illiteracy was eliminated among the 2.3 million illiterate people who accounted for 25 per cent of the total population at that time. Starting from September 1972 an 11-year compulsory education system was initiated and in September 1977 an outline for socialist education was formulated. Today in the DPRK, children must be enrolled from nursery to high school. At the turn of the twenty-first century, the DPRK has the Kim Il-sung Comprehensive University and 170 other institutions of higher learning, as well as over 500 secondary specialized schools.

In December 1952, the Korean Academy of Sciences was established. In February 1964, the Academy of Social Sciences was separated from the former Academy of Science, and then the Academy of Medicine, the Academy of Light Industry, the Academy of Education, and the Academy of Agriculture were established in turn. In the 1970s an institute was established within the Social Academy of Science to focus on Juche Idea research. Today there are more than one million scientific and technological experts in the DPRK. In half a century, the DPRK has made good progress in science and technology. Achievements include producing fertilizer with clean coal, producing vanillin with limestone and producing fibres with reed. In the 1980s, the metallurgical and casting industries advanced, and synthetic rubber and chemical fibres can also be manufactured domestically. The development of nuclear capacity in recent years also suggests a certain level of scientific competence.

Since the 1970s, both the arts and sports have developed considerably. The general Federation of Literature and Arts, made up of special arts unions for writers, musicians, artists and film artists have created literary and artistic works and given performances in accordance with Juche art idea. The opera *Blood Sea*, the novels *The Year 1932* and *Pyongyang Time*, the historic novel *Peasant War between 1894 and 1895*, and the film *Fourteen Winters and Springs* were all warmly received.

In sports, Koreans have broken world and Olympic records in shooting. Its female athletes won gold medals in the 33rd and 34th World Table Tennis Championships. A youth get-together was held in Pyongyang in early July 1989. Students from 180 countries and regions, representatives from over 60 international organizations and 470 senior officials from over 90 countries participated.

**The Republic of Korea**

The Republic of Korea (ROK), established on 15 August 1948, has distinguished itself in education, science and technology as well as culture during its first half century. After the mid 1980s, its economy took off and, together with other dynamic, export-led developing countries in the Asian region, it became known as a 'tiger' economy.

The ROK adopted a distinctive approach to education that guarantees compulsory education at the primary school level. Beyond the primary level, however, it offers two types of further education: formal education, which takes the form of junior school, senior school, elementary professional

college, college, university and postgraduate education; and informal education, which includes citizen school, radio and correspondence school, and vocational training. Expenditure on education represents 22.8 per cent of the total budget of the government, and 3.2 per cent to 3.4 per cent of the annual GNP. As a result, educational institutions have developed rapidly. According to the statistics of 1991, there were 8,400 nursery schools and the numbers of primary, junior and institutions of higher learning were, respectively, 6,000, 2,500 and 580. Primary schools students totalled 4.75 million and all children of school age were enrolled in primary school. Some 99.5 per cent of these primary school graduates entered junior schools, totalling 2.23 million. There were 1.54 million students attending institutions of higher learning.

In 1954, one year after the end of the Korean War, the Institute of Sciences was established under the Ministry of Defense, the first institute of its kind in the ROK. In 1958, the Atomic Energy Act was passed by the parliament and a year later, the Atomic Energy Institute was established.

Since 1962, the ROK has been formulating five-year plans to develop its economy and promote its science and technology. On 1 April 1967, at the beginning of the second five-year plan, the Ministry of Science and Technology was established, a state councillor was appointed as supervisor and the country celebrated its first Day of Science and Technology, which marked the beginning of a new push to develop its national capacity in science and technology. The Korea Science and Technology Research Institute and the Korea Academy of Sciences were established respectively in 1968 and 1971. The financial group for funding sciences was also established to guarantee academics enough money to cover their research. As a result, the country installed a comprehensive system for science and technology research. In 1973, the ROK launched a national scientific movement to gain international prestige with technology and set itself the target of becoming one of the 10 leading world superpowers in terms of science and technology.

In 1978, a nuclear reactor for generating electricity for commercial purposes was built. By the end of the 1980s, 12 nuclear power stations had been built and by the end of 1991, the installed capacity of nuclear power plants reached 17.616 million kw, 47 per cent of the total electricity generated in the country. The ship-building industries saw rapid development, too. From the 1970s to the 1990s, the automobile output rose from 30,000 to 1.96 million cars a year, thus making the ROK a major car producer in the world, even though the area of the country is less than 100,000 square kilometres. In the 1960s, electronic technology in the country was limited to the simple assembly of semi-conductors and radios; now it means such hi-tech products as complete information transmission systems, large screen digital colour TVs and laser disks. At present, the ROK is the world's second biggest manufacturer of video recorders, microwave ovens, and facsimile printers. It takes third place in manufacturing color TVs and telephones.

To realize the strategic target of becoming a superpower in science and technology, the ROK government and scientists spent 20 years constructing Taedok Science Town, an R&D science park that was completed in the early 1990s. Numerous research institutes and industries are located here with more than 70,000 specialists who work at the Korea Standard Science Institute, the Nuclear Power

Institute, the Electronic Communication Institute and Chungnam University. At present, another similar hi-tech town is under construction in Kwangju. The local governments of Pusan, Taegu, Jeonju and Kangnung also started similar constructions in 1993.

In the fall of 1993, EXPO '93 was held in Taejon, the third city in Asia after Osaka and Tsukuba in Japan to host such an event. Officially known as the Daejeon International Exposition, it was a kind of technological Olympics covering economics, science, technology and culture. At EXPO '93 Korean scientists demonstrated their achievements in such fields as resource utilization, information communication, space exploration, life sciences and environmental protection.

Post-war Korean society has witnessed a multi-faceted development. Under the 36 years of colonial rule and three years of war in the early 1950s, people suffered hardships and had no confidence in their future. Western existentialism took hold and influenced a young generation of artists and writers. *John's Collection of Poems* written by Chang Yong-hack, and *Square*, a best-selling novel by Choe In-hoon, were typical products. After the 1970s and the industrialization of the Republic of Korea, social conflict became increasingly evident as the two major ideological factions advocated either 'participation' or 'resistance'. 'Ozek', a poem written by Kim Ji-ha, a resistance poet, aroused people's concern with its attack on social injustice.

Despite the influence of American culture, many Chinese traditions persist. Koreans still practice Buddhism and Taoism, especially Confucian rites. The direct contact with Western philosophy intensified the interest in traditional culture and ideology.

The ROK has impressed the world with its flourishing sports scene, especially in ball games, water sports, wrestling, boxing and weiqi (also known as 'go'). In the 1982 New Delhi Asian Games, the ROK took third place, and in the 1986 Seoul Asian Games, it moved up to second place. At Los Angeles in 1984, it took 19 medals including six gold, six silver and seven bronze medals. The 1988 Seoul Olympic Games were a milestone in the ROK's sports history because South Korea was only the second country in Asia after Japan to host the Olympic Games, and it is the second capital of a developing country to welcome the Games, after Mexico City. The Olympic Center, Olympic Park, athletes' village and media centre were constructed especially to meet the needs of the Olympic Games. The ROK lived up to the name of sports superpower by taking fourth place in the world with 16 gold, 10 silver and 11 bronze medals.

## THE MONGOLIAN REPUBLIC

In the early twentieth century, the scientific and cultural levels of development in Mongolia were rather low. Influenced by the government's patronage of Lama Buddhism – the Yellow Sect – a great many men became monks. According to statistics, in the later Qing Dynasty, there were 747 temples and 105,577 monks in Outer Mongolia, constituting approximately 44 per cent of the male population. Before 1912, Outer Mongolia did not possess a single secular educational institution. Although modern civilization had already begun to spread in Outer Mongolia by 1915 – for example, with electric power plants,

workshops for the repair of firearms, and small-scale print shops, telephone companies, and telegraph bureaus – these modern facilities constituted a negligible share of the national economy.

In July 1921, the Mongolian People's Government, a constitutional monarchy, was founded in Ulan Bator with the aid of the Soviet Russian Red Army. In November 1924, the first convocation of the Great Hular, Mongolia's legislative assembly, ratified the constitution and pronounced the existence of the People's Republic of Mongolia.

Since 1921, the development of science, technology and culture in Mongolia has undergone three stages, corresponding to changes in its political and economic situation.

### 1921–1940 – development of democratic culture in a non-capitalist system

This initial stage of democratic cultural development in Mongolia began with a campaign to eradicate illiteracy. The campaign addressed not only lay people, but also lower-ranking monks as well. From 1935 to 1937, over twenty thousand junior monks participated in the study of Mongolian. By 1940, statistics suggest, 28.8 per cent of the population above 8 years of age was already literate – one of the principal achievements of the first stage of the Cultural Revolution. In 1921, Mongolia's first primary school was opened in the capital, Ulan Bator, and from 1922 schools for all social classes were set up one after another for each League and Banner (Mongolian socio-military administrative units), and in major residential areas. A financial management school was established in 1925, followed up by schools of veterinary medicine, telecommunications, and nursing in 1926, and the first normal school for training teachers in 1928. By 1940, the country possessed 319 primary schools, and the number of students was rising rapidly: the total of both primary and secondary school students surpassed 24,300, some 20 per cent of all school-age children at the time. Also in 1940, there were seven vocational schools educating 1,332 students, numbering 1.8 per cent of the population. In addition to education in these institutions, there were more than three thousand people receiving vocational training.

Mongolia's first scientific organization, the Institute of Economics, was founded in November 1921. It was devoted to research on language, literature, history, and folk customs. In December 1930, the Institute was enlarged to become the Committee on Science, to which agriculture and geology research departments were added. The Mongolian Institute of Economics and its successor, the Committee on Sciences, contributed greatly to research in Mongolian literature, history, geography, geology, botany, and animal husbandry. The various maps which they issued were of great assistance in the readjustment of Mongolia's administrative divisions, the exploitation of its natural resources and in planning its industrial distribution. The Institute's investigation of traditional pastoralism and breeds has raised the quality of Mongolian herds and increased herd productivity.

In the 1920s and 1930s, modern Mongolian literature progressed towards maturity. 'Yin He Ma,' 'Hu Qin Hu,' 'Country Scene,' 'First Moon Tears,' and the long poem 'My Motherland,' all by D. Nachukdolki, and the novel *The*

*Deserted Girl* and poem 'My White-Haired Mother,' by C. Damutinsulun – both founding fathers of modern Mongolian literature – are some of this period's most famous literary creations.

The curtain was raised for Mongolian stagecraft with the 1922 performance of the drama *Sando Minister*. Famous stage plays of the 1920s and 1930s include Nachukdolki's *Three Mountains*, *The Truth* by C. Buyanamohe, *Just Eighteen Years Old* by S. Ayouxi, and *The Wolf Pack* by D. Namudage.

During the same period, modern Mongolian visual arts and music also came into being. The painters Paledu Shalabu and D. Manebadar are especially well known; Manebadar excelled in his use of folk decorative patterns, and was deeply versed in traditional Mongolian fine arts. The most influential musician of this era was M. Dugarzhabu, one of the founders of modern Mongolian music, whose compositions 'The Red Flag,' 'Bounteous Mongolia,' and 'Little Cowherds' can still be heard today.

Mongolia's first cinema, the People's Movie House, opened in Ulan Bator in 1934. The nation's first motion picture studio was established in 1936, producing the film *Mongolian Man* as its first feature. In 1931, the Soviet Union helped Mongolia to construct its first radio station, which began broadcasting in May of that year.

The first modern hospital in Mongolia was established in October 1925 in Ulan Bator, staffed by Russian doctors. By 1940, Mongolia had a total of twenty hospitals, in addition to 177 branch hospitals and clinics as well as 923 native doctors and nurses.

Before the 1920s, Mongolia's principal athletic activities consisted of the traditional 'Thirteen Feats' (for men) – among them horse racing, wrestling and archery. But in the 1920s, modern sports began to spread in Mongolia, becoming popular mainly in the army, schools, and among the youth.

## 1941–1990: bypassing capitalism to formulate and develop a socialist culture

The Mongolian government succeeded to a high degree in combating illiteracy. According to statistics from 1971, 67 per cent of the population between the ages of 13 and 49 attained at least the primary school level of education. By 1975, that proportion had risen to 74 per cent. In the process of fighting illiteracy, the Mongolian government had decided to reform the writing system, replacing old Mongolian with a new Mongolian written language, accelerating to a certain degree the pace of the anti-illiteracy campaign. The development of ordinary and vocational education was likewise rapid. In 1960, Mongolia achieved its goal of educating all school-age children through primary school. In 1962, there were 419 ordinary schools, up to 570 by 1978. In addition, special schools were opened for orphans and for the physically and mentally handicapped. In 1965, the country possessed ten vocational schools, training two thousand students; by 1980, these figures had risen to 37 and 22,100, respectively. Between 1960 and 1980, the number of secondary school students more than tripled, from only 6,900 to 23,200.

The Soviet Union and other countries also contributed to the development of Mongolia's human resources, training more than 2,200 experts in their universities and polytechnic institutes. More than 90 per cent of the higher academic degrees held by Mongolian scientific research personnel between 1940 and 1960 were received from the Soviet Union. The Mongolian National University (MNU) was founded in October 1942. From 1942 to 1991, more than 27,300 students graduated from the University, and among them seventy-one doctors of science, 671 doctoral associates, twenty-six professors, sixty-five associate professors, thirty members of the Academy of Sciences, three national labour heroes, and twenty-nine recipients of national honours. At present, MNU contains four teaching and scientific research institutes, two affiliated colleges and research centres, more than a dozen laboratories, four departments, forty teaching and research sub-sections, nearly four hundred teaching and scientific research personnel, and trains 2,390 undergraduates and more than sixty postgraduate students.

With the expansion of scientific endeavours in Mongolia, the country's scientific institutions underwent several readjustments. In May 1961, the Mongolian Committee on Sciences and the Committee on Higher Education were reorganized into the Mongolian Academy of Science. However, the basis of science and technology in Mongolia was still weak, and progress was slow. The major scientific achievements of this period include the following.

Research in animal husbandry and veterinary medicine produced high-quality academic papers such as 'Surgical Therapy for the Treatment of Yak Dizziness,' and 'Sheep of the Gobi and Altai'. Contemporary husbandry and veterinary medicine began to make inroads; and new livestock breeds like the half-fine-hair 'Erhun' sheep and the Gobi Gurvan Saikhan goat were being raised. In agriculture, new 'Erhun' wheat was introduced, and new varieties of fruit trees were experimentally tested. Rapid growth occurred in geological and geographical research and mineral prospecting, with substantial results. Exploration and mining in the Erdunte region, where Mongolia's massive copper and molybdenum deposits are located, has been going on for twenty years, which constitutes the greatest achievement of Mongolian mining development and of Mongolian-Soviet cooperation. The copper and molybdenum produced there accounted for the largest share of foreign currency earned by Mongolia, and were one of the pillars of its economy. Since the 1960s, Mongolia has explored more than five hundred sites for mineral deposits and apparent deposits, among them rare and precious metals, ferrous metals, coal, and precious stones. Mongolian geologists have produced geological maps of varying scales. Another important achievement of the country's geologists and geographers is publication of the *Atlas of the Mongolian People's Republic*, which consists of two principal parts: 'Natural Conditions and Resources,' and 'The National Economy'. The Atlas is 144 pages in length, and contains 276 maps and charts, systematically analyzing Mongolia's natural geography, economic geography, and political geography.

In the field of space exploration the Mongolian astronaut Gurragcha successfully participated with Soviet counterparts in a 1981 space study mission.

In the social sciences, Mongolian scientists have carried out extensive research on their country's history, language, literature, philosophy, and economy, and have published numerous monographs and books, such as *The General*

*History of the Mongolian People's Republic, Ethnology of the Mongolian People's Republic, Modern Mongolian Language, Modern Mongolian Grammar and Phonetic Structure, Young People's Encyclopedia, Comprehensive Dictionary of Mongolian Customs*, and so on.

Mongolian literature flourished during the 1940s. The major achievements consisted chiefly of works praising the Mongolian people's patriotism during the Second World War and the friendship between Mongolia and the Soviet Union. In the 1950s, Mongolia published its own full-length novels *The Dawn* and *In Altai*, marking a new stage in the development of Mongolian literature. In the 1960s, the novels *Crystal-Clear Tamir River, Years of Turmoil, Mountain Torrents, Mobile Seats, A Great Destiny* and *The Clatter of Hoofs* were published, as well as collections of poetry by Gaitabu, Yawuhulang and Puribudaorji. Among these the most popular was *Crystal-Clear Tamir River* by Luodaidanba, which vividly and movingly depicted the panorama of life and customs in Mongolian society during 1920s. Since the 1940s, Mongolian drama has evolved briskly; many richly themed works have been staged, including the historical plays *The Wise Mandu Sea Queen, Arquirshana*, and *The Khan of Shalai River. The Birthday* and *Brothers* depicted the joint Mongolian and Soviet struggle against Japanese militarism in the Second World War; and others reflected the life of the Mongolian people after the war. In the 1940s, Mongolian cinema was predominantly aimed at promoting patriotism.

Mongolian efforts in medicine and health care also developed apace. In 1960 there were 630 hospitals and clinics, equipped with 8,303 hospital beds. These figures had increased greatly by 1980, at which time Mongolia possessed 2,541 hospitals and clinics, and 16,503 hospital beds, and the basic level of health had reached a relatively high level.

### Since 1991 – the impact of economic crisis on Mongolia's science and culture

After the collapse of the socialist system and disintegration of the former Soviet Union, trade declined sharply from 1989 to 1993. Since August and September 1990, Mongolia's economic condition has steadily worsened. For example, the gross national product for 1991 was down by 16.1 and 12.8 per cent from 1989 and 1990, respectively; the industrial output fell by 16.7 and 11.7 per cent; agricultural output (including animal products), fell by 6 and 2.4 per cent in the same period. In 1992 the Mongolian economy continued its downward slide.

The declining market for cultural production, a shortage of funding for scientific research and stagnation in educational progress, were increasingly evident. To take education as an example, in 1991 the number of school drop-outs reached 20,100; only 11 per cent of planned school construction was finished and the opening of 109 schools was delayed. About 45.5 per cent of kindergarten buildings were serving purposes other than those for which they were meant; while another 22 per cent was in danger of collapse. Schools and kindergartens in rural areas were short by more than 430 teachers. Since 1994 however, the economy has rebounded somewhat, showing a growth of 6.3 per cent in that year, but the task of recovering lost ground in cultural and scientific development remains critical.

## CENTRAL ASIA

Between the seventeenth and nineteenth centuries, the socio-economic situation in Central Asia had hardly changed at all. The feudal age continued even as capitalist relations were taking root in society. A peculiar feature was the combination of essentially feudal economies with patriarchal social relations that coexisted with many remnants of tribal forms of living. The tribal form was actually a legal fiction disguising private ownership of land and cattle. Feudal ownership was combined with a small centralized state having little internal unity. Exploitation and arbitrary rule increased from year to year. Feudal rents were becoming more and more ruinous. The system of granted land estates and *waqf* property – an Islamic legal term for land dedicated to religious purpose – were helping the feudal ruling class to maintain their wealth. A slave trade had existed everywhere since ancient times, especially in Bukhara and Khiva. Arminius Vambery, a nineteenth-century scholar and traveller, informs us that there were 20,000 slaves in Bukhara alone. Class differentiation was rather significant. The intermediate producers and the peasants were exploited by the state through imposition of *kharadj*. In Bukhara, for example, an extraordinary war tax was levied at the same time as many other duties. Abuse on the part of the ruling class caused a great uprising among the Kipchak population in 1821.

In some cases, when arbitrary rule and coercion became intolerable, in particular on the part of Khiva and Bukhara authorities, groups of Turkmen migrated to the Astrabad region, and Tadjiks and Uzbeks went to Afghanistan. The northeastern borderlands of the khanate were populated by Karakalpaks, who had settled here along the Amu Darya river in the early nineteenth century. The economy was based on agriculture and cattle-breeding. Here Uzbek feudal lords had dominated the landless populations, and played an important part in the social and political life of the Khivan khanate. Military conflicts between Bukharan and Khivan Khans were frequent. A Turkmen tribe, the Yomuts, was a principal force in the Khivan invasion. The Karakalpak population, left without military assistance from the Bukharan emir, had to submit to Khiva in the first decade of the nineteenth century. Khan Mohammed Rahim occupied a rather important place in the Khivan khanate in the first half of the nineteenth century. He succeeded to a large degree in centralizing the state and strengthening central power. After several wars he captured the Aral regions and also undertook several campaigns against Kazakhs. Merv, an important Turkmen centre, submitted to Khivan power in 1822. This all resulted in significant expansion of the territory. The new evolving state was largely dominated by the clergy, who enjoyed certain privileges. Its armed force was principally represented by *noukers*, whose occupation was to run either before or after the mounted horseback riders. Half of all cultivated lands belonged to the Khan and his relatives; the clergy, the merchant class and general population were considered legal tenants. A land tax was paid in money and in kind. Turkmen, Karakalpaks and Kazakhs suffered most from these taxes, and the number of slaves was significantly greater than in neighbouring feudal states. Arbitrary rule and violence had caused an uprising headed by Er Nazar, a Karakalpak chief, whose heroism will remain forever in the history of the Karakalpak people.

Up to the end of the nineteenth century certain unification trends were becoming visible among heterogeneous population groups of the Fergana Valley under the Khan Umar (1809–22) and his successor Madali-khan (1822–24). The city of Kokand had appeared earlier in the Fergana Valley, in the middle of the 1700s, surrounded by densely populated areas. Nobility, the owners of large land estates, dominated the region with its settled population. In the 1800s political domination shifted to Fergana hojas, who concentrated political power in their hands for some time. The second ruling group consisted of middle landowners who remained the mainstay of state power and also commanded the armed forces of the khanate. The highest ecclesiastical dignitaries, represented by *qadis* or judges, as in Bukhara and Khiva, held responsibility for general supervision over activities of the clergy. Local historian Mohammad Khakim believes there were as many as 40,000 officials in Kokand. Just as in the neighbouring states, owners of *waqf* possessed great financial means. The *kheradje* was a principal tax imposed on the great number of landless peasants who were also obliged to rent land. Their earnings with small parcels were very low and they often substituted their labour in place of cash levies. Peasants were legally free, but as a result of indebtedness to the state as well as general economic dependence on large landowners, they were not free in practice. The Kipchaks maintained a traditional patriarchal kinship system with strong tribal chiefs. The nomadic population, especially Kirghizes of Kokand khanate, preserved the khan's charters confirming possession of their lands.

As to culture and education, there were schools of two different kinds in this part of the Islamic Orient. *Maktabs* were primary schools where children from the age of 6 to 15 years received their education. A graduate was expected to know the basic obligations of a Muslim and understand the religion's dogmas. Lectures were read in Arabic and Farsi languages. In larger cities, separate schools for girls also existed, with a reduced curriculum. Similar schools functioned among nomadic Kirghiz, Kazakh and Turkmen populations. The higher-level Muslim schools were called *madrasas*. These were also confessional, and their curriculum was based mainly on scholastic theology and the *Sharia* as well as Muslim canonical law. Educational institutions were maintained from incomes on *waqf* lands and other property. For the most part, both *maktabs* and *madrasas* were concentrated in large cities, especially in Bukhara, Samarkand and others. Education was entirely in the hands of the clergy, and the level of knowledge was generally low.

Notwithstanding this, Bukhara *madrasas* attracted many people not only from Central Asia, but also from the Volga regions and Orenburg. Since ancient times Bukhara had enjoyed a reputation as a holy city and also as a centre of sciences and education.

All in all, the central cities, best typified by Bukhara and Samarkand, are of the greatest historical and cultural interest. *Madrasas*, which played a significant part in the life of this region, gave to the world such famous thinkers as Al-Biruni, Avicenna, Nosiri Khosrov and many others. Such splendid monuments as the Samanids Mausoleum (ninth century) in Bukhara, the Kalyan mosque and Miri-Arab *madrasa* (fifteenth century), Baland and Hoja Zainuddin mosques (sixteenth century), and the great mausoleums of the Shah-i-Zindah, Bibi-Khanum and Gur-Emir are known throughout the world.

Together with official theology, Sufism with its dervish orders also played a significant part here, with Timur's contemporary Hoja Bekha-ud-din the most prominent Sufi. The Central Asian writer Sadriddin Aini once remarked about these splendid monuments: 'magnificent and luxurious from their facades, cramped and uncomfortable inside, these buildings seem to reflect the hypocrisy, hostility and outward splendor of the feudal age'.

Towards the end of the eighteenth and beginning of the nineteenth century, certain progress in market relations was becoming visible. Some individuals concentrated not only on large land estates but also on trading and managing artisan enterprises. At the same time feudalism was a brake on such developments. The population at large and those in cities found that economic ties were severed or made difficult by the borders as well as by intermittent clashes and wars among the three large khanates.

The feudal khanate was a little centralized state. Exploitation and feudal arbitrary rule were increasing from year to year. In Bukhara, a new bazaar levy, the *aminona*, was introduced, and Emir Nasrulla introduced a *yarga* tax and forfeiture of property. In 1859 all this resulted in a civil war, with Kazakhs, Karakalpaks and Turkmen laying siege to the Kungrat dynasty capital. In the second half of the nineteenth century British imperialism in Central Asia was at its most aggressive. At the same time, Czarist government policy in the region was being dictated by the colonial ambitions of Russian capitalists seeking foreign markets, and by its strategic situation. Sometimes the conquest was by force, but in other cases it took more peaceful forms.

In 1861, Orenburg's Governor-General drew up plans for capturing Turkestan and Tashkent. Two detachments were sent, one commanded by Colonel Mikhail Chernyayev, and another under Colonel Nikolai Aleksandrovich Veriovkin. In May 1864 Chernyayev stormed and captured Aulie-Ata, and Veriovkin captured the large cultural centre of Tashkent. In September 1864 Chernyayev began siege of Chimkent, which at that time was subjected to Kokand khanate rule, and captured it after several clashes with Kokand troops. In October 1865, Chernyayev reached the fortress of Niez-bek, where he defeated Bukharan troops and captured Tashkent. To accelerate the conquest, General Romanovskii was detailed to Turkestan to succeed Chernyayev, who continued his offensive against the Bukharans. Khodgent fell to the Russians, as did Ura-tiube, Samarkand and Kokand. Meanwhile Emir Muzaffar proclaimed 'holy war' against the Russians. But he lost the battle of Djizak on the approach to Samarkand and Russian troops continued their offensive into the Bukharan territory. Up to this time the Turkestan Government under General Konstantin von Kaufman was established on land conquered since 1847, with Tashkent as its centre. In the summer of 1868 a peace treaty was concluded between Russia and Bukhara, leaving the latter a vassal of Russian Czarism. In the spring of 1870 Russian troops occupied all the territory along the Zeravshan River and invaded Khiva, which was captured the same year by Russian troops commanded by von Kaufman. Then Russia seized the opportunity provided by an uprising in the Kokand khanate and conquered the whole of it in 1876. The road was open for further movement toward Turkmen territory, particularly Kizyl-Arvat and the western part of the Akhal-Teke oasis. A new expeditionary army, headed by General Mikhail Skobelev, was formed in 1881. Skobelev immediately moved his troops

against Geok-Tepe, and on 28 December engaged in a famous skirmish that ended in hand-to-hand combat. On 12 April 1881 the fortress of Dengil-Tepe was stormed and taken, and Ashkhabad surrendered some time later. The fate of the Turkmen was finally decided. On 6 May 1881 the Trans-Caspian Province, which included newly conquered regions, was established with Ashkhabad as its centre. In 1887 a new northern border was drawn between Russia and Afghanistan up to Zarkul lake. Khiva, like Bukhara, was declared a vassal of Russian Czarism.

After the conquest was completed, the peoples of Central Asia and Kazakhstan lost their independence and from then on lived in a state of political disintegration.

In the wake of the October Revolution, a wave of revolutionary fervour swept the whole country, including Central Asia – Kazakhstan, Uzbekistan, Kirghizstan, Tadjikistan and Turkmenistan. Faced with radical changes, these tradition-bound peoples were able to achieve great success in industry, agriculture and culture during the twentieth century. Often their successes were rooted in friendship between peoples and the mutual assistance inherent in the social life of the country. Guided by principles of international solidarity, the international community has also played an important role in the daily lives of people in Central Asia.

After 1917, the equality of nations and the equal right of national minorities to freely develop in their own way became a reality, and everything was done to improve their economic and cultural level. Full equality of women and freedom of conscience were recognized, while the remnants of the old society were suppressed. The People's Commissariat of National Affairs was established after the Fifth All Russia Congress of Soviets in 1918, with the purpose of promoting all possible measures for cultural development and class-consciousness.

In 1918 the Turkestan Congress of Soviets confirmed recognition of the local language as a state language, and decided to publish literature in all local languages. A great effort was made to expand the network of general education schools, to offer courses for protection of cultural heritage and historic monuments, and to create a Soviet press that would publish literature in local languages. Commissions were set up to eradicate adult illiteracy, which was the greatest brake on economic progress and cultural revolution. By 1924–25, literacy in Turkmenistan alone had already increased 4.7 times as compared with 1920. Organization of Soviet General Education began to provide schooling for children without distinction of age, nationality or religion. Short teacher training courses appeared in Turkestan and Kazakhstan to train teachers for the national and primary schools. Some time later similar schools were opened among the nomadic and semi-nomadic population. In 1920, 35 Turkmen schools opened in Poltoratsk Uezd (district), with 1,500 boys and girls of all ages. During the first three years of Soviet power in Turkestan the number of schools opened each year averaged 75, five more than during the fifty years of Czarist domination.

At the same time, out-of-school education was rapidly progressing for all strata of the population. For example, there were 17 such schools in Przheval'sk Uezd of Kirghizia. Because of classroom shortages for nomadic peoples, some schools opened in yurts. In 1918 the school reform in Kirghizia was completed, and consolidated labour schools replaced the former estate schools. New requirements and new methods were introduced for both Russian and indigenous pupils, due in part to the influence of the First Congress of Popular Education of Turkestan, held in 1918. In September of the same year a similar congress took place in the Bukei Horde in Kazakhstan.

On 21 April 1918 the Turkestan People's University was opened. In September 1920 the Central Asian University in Tashkent was founded, and many of Russia's best scientists and scholars came there to teach.

Political news and opinion was provided by central organs like *Pravda* and *Izvestiia*. In Tashkent, *Nasha gazeta* (Our Newspaper) appeared for the first time on 2 April 1917. Later, publication of republican newspapers started, *Izvestiia Tsik, I Sovnarkoma Turkestanskoi respubliki* (News of the Central Executive Committee and the Council of People's Commissaries of the Turkestan Republic), *Krasnoarmeets* (Red Army Soldier) and *Golos Krestianina* (Voice of the Peasant) among them. In June 1918, the first issue of an Uzbek-language newspaper was published. Newspapers in Tadjik and other languages of the peoples in Central Asia followed, as did new locally produced magazines.

One of the greatest successes was the emancipation of women in Central Asia, which was seen as an essential part of the proletariat's struggle for its liberation. There were many obstacles due to vestiges of feudal and patriarchal societies, total illiteracy of the population, and such traditional customs as obligatory wearing of the *paranja* (veil), and arranged marriages of teenage girls. It is in these years that many oppressive practices against women were put to rest.

From October 1917 to March 1918 the Soviet power marched triumphantly through Central Asia and Kazakhstan. Turkestan joined the RSFSR as an autonomous republic. It included all of Turkestan within its geographic borders excluding Khiva and Bukhara. The bulk of the population consisted of Uzbeks, Kazakhs, Kirghizes, Tadjiks, Turkmens and Karakalpaks. The idea that power belonged in the hands of workers and poor peasants provided strong revolutionary motivation for the toiling classes of Khiva and Bukhara, where semi-feudal regimes still existed. But they were resisted by the Bukharan and Khivan khanates, who were hostile to reforms undertaken in Soviet Turkestan and Kazakhstan.

In February 1920 a great uprising against the feudal regime of Djunaid-khan began in Khiva. Local progressive intellectuals turned to the government of Turkestan and to the Turkestan Commission for support. Russian revolutionary troops defeated Djunaid's bands and Soviet power was established in the city.

In April 1920 the first All-Khivan Kurultai (council) of people's representatives was convened in Khiva. It proclaimed the Khivan khanate abolished and inaugurated the Khorezm People's Soviet Republic (KhPSR). In 1921 the Soviets deposed the young government of the People's Republic of Khorezm, later replacing it with the Khorezm Soviet Socialist Republic (SSR), and also abolishing the voluntary incorporation of the respective ethnic regions of Khorezm into the Turkmen SSR, the Uzbek SSR and the Karakalpak Province (Karakalpak Autonomous Soviet Socialist Republic since 1932). Meanwhile, a revolutionary crisis was brewing in Bukhara. On 6 September 1920 revolution broke out and the Emir fled. On 6 September 1921 the All-Bukharan kurultai adopted the Constitution

of the Bukharan People's Soviet Republic (BPSR). These popular-democratic revolutions in Khorezm and Bukhara were brilliant proof that it was possible for some traditional peoples to pass to socialism directly without passing through a capitalist phase. Trained personnel were scarce, and the old intelligentsia was widely employed when available. Nevertheless, the process of attracting the old intelligentsia to the side of Soviet power was slow and irregular, and a big effort was made to train new personnel in keeping with the new spirit.

There were many different levels of development among the peoples of Central Asia. Some peoples possessed a bourgeois intelligentsia, while the others did not. Representatives of other nationalities and groups, Russians, Tatars, Jews and others, were employed in leading industries of the national economy together with representatives of autochthonous nationalities. The central educational institutions in various branches of science in large cities played a major part in training highly skilled professionals. Such institutions as the Institute of Red Professorship, the Communist University of the Peoples of the Orient and others also helped develop leadership for the national republics, while other institutions, from *rabfak* (workers' faculties) to the largest educational institutions in big cities like Moscow and Petrograd trained personnel for local teacher training colleges. In the early 1930s teacher training institutes and universities were opened in many republics of Central Asia and Kazakhstan, and specialized medical, agricultural, and veterinarian institutes started functioning in the Asian capitals. Highly skilled specialists were invited from other republics to help out, and they rendered great service in developing national capacity. Large industrial enterprises began to appear on the base of pre-revolutionary handicraft shops. Up to the time of the national-state delimitation in 1924, literacy rates in Uzbekistan alone had increased more than three-fold. As early as 1926 there were 913 general education schools in Uzbekistan with more than 77,000 pupils, and two higher education institutions in Tashkent and Samarkand. By 1938 there were 30 higher education institutions in Uzbekistan with 15,600 students. By the late 1920s and early 1930s it was becoming necessary to centralize research, management, education and planning around single centres. In Turkmenistan, formerly a very weak republic, such a centre was established in 1927 to unite all branches of science. At this time, a planned and concerted research effort to explore the Kara-Kum Desert began in Turkmenistan.

In October 1940 the Turkmenistan branch of the Academy of Sciences of the USSR was founded. Special attention was paid to making more rational use of desert pastures, and new forage plants of the cotton family with higher albumin contents were introduced.

The first conference devoted to natural resource problems of Tadjikistan took place in Tashkent in 1925. Its objective was to initiate a comprehensive study of natural resources and cultural heritage of the Tadjik people, beginning with research on the physical geography and economy of Tadjikistan. In the same year, two research expeditions conducted geological surveys and collected anthropological and linguistic materials.

In 1928, an expedition to Pamir was organized jointly with German researchers. This expedition resulted in the discovery of several glaciers and névé fields in the northwestern corner. In 1930, the USSR Academy of Sciences held a conference on geological and surveying work in Dushanbe. In 1931, the first congress on non-ferrous and rare metals took place in Khodzhent, and in 1933, the Academy of Sciences organized a conference in Leningrad devoted to modes of energy production and industrialization in Tadjikistan.

Great changes were occurring in the republic. If there were only 60 industrial enterprises in Tadjikistan in 1932, then this number had increased to 209 in 1937. A metalworking industry was created, and a machine production and repair facility was constructed in Dushanbe. Besides cotton-cleaning plants, there was silk-processing, leatherworking, and garment-making.

On 14 April 1951 the Academy of Sciences of Tadjikistan was established, which played an enormous role in furthering development of science and culture in Soviet Tadjikistan through economic growth and better management and use of natural resources. From 1 January 1945 through January 1946 more than 20 new industries became operational. By the 1960s, the construction and transportation industries were developing vigorously. Later enterprises included an oil and fats plant, a carpet-making plant, textile manufacturing, electrical equipment, and a mining and mineral extraction plant in Adrasman. Industry became the backbone of the republic's economy. Goods manufactured in Tadjikistan were exported to many other countries. Great attention was also paid to development of cotton plantations in the Vakhsh Valley, construction of irrigation canals, reclamation of uncultivated lands, construction of power plants, and development of such varied scientific disciplines as seismology and gastroenterology. The principal goal was always to accelerate the rate of technological progress.

These successes would not have been achieved without the support and assistance of the more developed republics in the Soviet Union. In 1924, the Kara-Kirghiz Autonomous Province was constituted within the RSFSR (Russian Soviet Federated Socialist Republic). This significant event brought the first statehood to the Kirghiz people and in December 1936 it became a Union republic. In August 1954 the Academy of Sciences of the Kirghiz SSR was founded as a branch of the Academy of Sciences of the USSR. Originally, the Academy consisted of the Institutes of Geology, Botany, Water Resources and Energy Technologies, Zoology and Parasitology, Regional Medicine, History, Language and Literature. In 1956 the first scholarly works on the anthropology of the Kirghiz people were published. The same year saw publication of a two-volume *History of Kirghizia*. These Highland cattle-breeders from ancient times had their poets and singers like the famous Toktogul (1861–1933). The vast spiritual heritage was passed from one generation to another through the epic *Manas*, which contains more then a million lines of verses and is 20 times bigger than the *Odyssey* and *Iliad* together. It appeared more then a thousand years ago and sings the tale of the legendary Kirghiz hero Manas, giving a history of the people. In 1958 sub-disciplines on materials science, philosophy, and several laboratories were added in the Institute of Economics. From 1964 to 1979 new departments of physics, mathematics, chemistry and life sciences were established in the framework of the Academy of Sciences. By the beginning of the 1990s more than 1,200 researchers worked in the Academy, which was playing a leading role in national development. Great successes were achieved in seismology, especially with regard to techniques of seismic mapping.

Scientists and engineers from several research institutes of the Academy of Sciences of Kyrgyzstan carried out extensive geological, climatological, geographic and seismological studies around the Aral Sea and Lake Balkhash, and the construction of water reservoirs was planned. Engineers there analyze and test the best methods of building dams in the mountains in Kirghizia, Tadjikistan, Armenia and Georgia. Scientists in Kirghizia also do significant work on fine-fleeced sheep-breeding (there are 12 million of such sheep here), which attracts very large investments.

The high and powerful Tokhtogul dam is situated on Kirghiz territory, as is the dam of the Nurek power plant, a unique engineering work, situated in the southern highlands. Construction of these dams seemed to offer proof of the great potential of socialism and of the friendship of peoples. The Nurek dam is also recognized as being the world's first installation with a high head of water to be constructed within the grade 9 zone of seismic activity.

The USSR Academy of Sciences played a tremendous part in fostering scientific development and establishing satellite academies throughout the Central Asian republics. In their turn, the academies achieved prominence in selected fields within the broader system.

In August 1920 the autonomous Kirghiz (Kazakh) Soviet Socialist Republic was constituted within the RSFSR, with its capital in Orenburg. The republic included regions with predominantly Kazakh population around Semipalatinsk and Aktiubinsk. Later some territories were transferred to Kazakhstan. Grouping of Kazakh lands under a single authority made it possible to constitute a Union republic, with the capital in Alma-Ata.

Kazakhstan scientists achieved much in Earth and metallurgical sciences, mining, biology, molecular chemistry, astrophysics and social sciences. The country serves as a good example of the importance of fundamental research. Thanks to research in the social sciences, many economic, ideological, social and legal problems were resolved, including issues touching on spiritual culture, language, literature and art. In the prewar years, more than 2,580 large industrial enterprises were operating in Kazakhstan. At the same time secondary and higher education institutions were created in many specialized fields like teacher training, medicine, and veterinary studies.

Kazakhstan and Uzbekistan differed from the other republics of Central Asia by the size of their population and area, as well as by their wealth of internal resources. Kazakhstan possessed great masses of cultivated land, while Uzbekistan had great cotton fields in addition to its industry. Crops from these republics not only supplied the USSR but were exported to foreign countries. Successful economic and cultural development of these two republics was promoted not only by assistance and support from the Soviet Union but also by the presence of large numbers of people of Russian origin. As a whole, internationalism was always a distinctive feature of the Central Asia population, and they flourished especially in the years following the Second World War. Kazakhstan State University in Alma-Ata was a major institutional force in the region's development. Scientists in Central Asia conducted joint research on the area's natural and social resources. They prepared topographic maps of southern Tadjikistan and at the same time studied nuclear physics and space rays. The USSR Academy of Sciences coordinated and determined the main directions of research done by the national academies. Up to the 1970s the number of scientific personnel in Kazakhstan exceeded 11,300, with 4,400 of them involved in research. Along with great scientific and industrial successes the republic made great strides in agriculture. Cultivation of the virgin lands began in this period and there were great harvests of grain. In Turkmenistan, after its Academy of Sciences was founded in 1951, there were 41 functioning scientific institutions with 656 Doctors of Science.

Scientific research and cultural development were also promoted through conferences to discuss large-scale projects and economic prospects. Construction of Turkmenkanal (Turkmenian Canal) to the Amu Darya River, a tremendous project, was an invaluable incentive for development. It made possible reclamation and cultivation of the Kara-Kum Desert, construction of new cities with large populations and gardens, and the beginning of cotton-growing in these areas. Turkmenistan is now an important supplier of oil and gas, as well as a great industrial and cotton-producing region. The republic possesses universities and institutions for medical, agricultural, pedagogical, and polytechnic training, and other higher and secondary educational institutions. During the Great Patriotic War (the Second World War), Tashkent, Alma-Ata and other cities became not only bases for enterprises evacuated from Russia, Ukraine and Belarus, but also centres for relocated scientific institutions. Many great specialists were brought in along with the plants and factories, a process that facilitated training of national cadres from among gifted young people. Local research institutions began publishing works on the history of their peoples with the help of Russian and Ukrainian scholars, thereby strengthening friendship between peoples and giving a new impetus to internationalism. With the help of the USSR Academy of Sciences, new scientific institutions were established in larger cities. Uzbekistan scientists, for example, were well known for their work in nuclear physics, solid-state physics, mechanics and seismology. Fundamental research was especially successful and proved increasingly useful in developing new technologies and materials, instruments and equipment. For the first time scientists successfully predicted an Earthquake in the Alai Valley in 1979 and were accurate to within a few hours. More than 600 foreign scientific delegations visited Uzbekistan alone and 39 international symposiums were held there.

As to other neighbouring republics, Tadjikistan should be credited with notable scientific successes, built on continuing advances in the disciplines established from 1959 to 1972: astrophysics, seismology, organic chemistry, biology, mathematics and physics. In humanities, the histories of the peoples of Central Asia were published in all republics beginning in the 1950s. Contacts with various scientific centres and organizations greatly expanded. For example, the Tadjikistan Institute of Chemistry studied brown coal deposits in the Uzbek and Kirghiz Republics. The Institute of Biophysics and Physiology of Plants discovered several new species. The Gissar Observatory made high-precision measurements of space stations *Mars 3*, *Luna 181* and *Luna 191*.

The growing prosperity of people in the USSR boosted the mass media there; more than 180 million readers of all nationalities can read printed works in 89 different domestic languages and 56 foreign languages. In 1914 there were no general libraries in Uzbekistan, Tadjikistan, Kirghizia,

Turkmenistan and Kazakhstan. Now each of the republics possesses public libraries with great collections of literature. In 1972, some 1,398 public libraries in Kirghizia kept 12,038 thousand copies of books and magazines. In Uzbekistan, the number of libraries had increased from 3,418 in 1960 to 5,909 in 1972, and their collections grew from 18.4 million to 34 million volumes; for the Tadjik SSR, the respective figures are 884 and 1,242 libraries and 4.9 million and 8 million volumes, for the Turkmen SSR 1,168 and 1,185 libraries and 560,000 and 6.9 million volumes.

Uzbek, Tadjik, Turkmen and Kazakh literature has achieved extraordinary heights. Already in the prewar period, contemporary literature was making inroads and writers and poets such as K. S. Aini, M. Aibek, Mirzo Tursunzade, G. Guliam, V. Kerbabaev, Chinghiz Aitmatov and others became well known even abroad. In recent years many talented artists of the former Union republics have also received international attention.

Each republic was proud of its culture and achievements and each nation and nationality had always preserved its peculiar features, national character, language and traditions. Soviet culture and science embraced all the best features. Soviet literature and art constantly reflected the unity of international and national themes, especially when describing social processes and issues.

With each year international contacts were strengthened and joint research with outside institutions increased, especially with those in Eastern Europe. Young people from the Middle East, Africa and Latin America came to study in Central Asia. The bonds of local unity and cohesion were very intense, a sense of solidarity that was well demonstrated during the hard times of the Second World War. Coming back to the present, all countries have witnessed changing priorities in fundamental and applied sciences as market relations play an increasing role in determining the speed and nature of technological renewal. As market conditions are applied to science, priorities set through competitive selection will decide which projects are implemented.

In recent years, the reform process in Central Asian countries of the Commonwealth of Independent States (CIS) has been gradually expanding. In Kazakhstan, for example, quantitative and qualitative changes are actively under way. The crisis in the chemical and energy industries has now stabilized and since 1994–95 the main emphasis has turned to better management of the republic's own resources, a balanced budget and less dependence on foreign loans. The pace of change and reform is different in each country, but the process is the same.

# OCEANIA

## Roy Macleod

## INTRODUCTION

Fifty years ago, on 6 August 1945, a B-29 of the US Air Force called *Enola Gay* took off from Tinian, a tiny island in the northern Marianas, and dropped the first atomic bomb on Japan. Following Hiroshima and, two days later, a second bomb on Nagasaki, the Pacific War came to an end. A prodigious fear of Western science and technology had helped curtail the world's most costly war. This moment – of lasting global significance – marked also a moment in regional narrative, a dramatic instalment in a long history of Western science and practice, which had for centuries made a laboratory of the Pacific. From Magellan's voyage round the Horn in 1520, to the American sortie from Micronesia, the Pacific had become a contested space for discoverers and explorers, missionaries and colonizers, naturalists and anthropologists. First sighted by oceanic navigators from the Indonesian archipelago around 20,000 BC and settled by 1000 AD, the region we now call Oceania became, by the nineteenth century, a tropical necklace of colonies – and as such, projections of Europe. Its places, its peoples have inspired Western art, science, literature, and scholarship. At the close of the twentieth century, the future of the Pacific cannot be understood without an appreciation of its past and those factors that have shaped its present.

That present is now viewed with an insistent eye. Today, fifty years after the end of the war, the island nations of Oceania, and the countries of Australia and New Zealand, reveal a history of settlement and assimilation of Western culture – separated in many respects from Asia and the civilizations of the Pacific Rim. Within these fifty years, however, has emerged a sense of political and cultural independence, which is testing historical relationships with the superpowers and the cultural assumptions of the West. This fact alone has obliged the world to take an increasing interest in the region, and its Rim, on the eve of what is heralded to become the 'Pacific Century'.[1]

## OCEANIA AND ITS PLACE IN THE WORLD

In the map collection of the National Library of Australia, 'Oceania' first appears on the map by Abraham Ortelius,

entitled Maris Pacifici, dated 1589. It is the name now given to the many islands – geographers estimate between 20,000 and 30,000 – that are scattered on a line 17,000 km across the south and central Pacific, an ocean that covers a quarter of the world. Some of these islands are thousands of square kilometres; others are mere volcanic peaks barely visible above the water. The population of the region now comprises 8.5 million people, shared among nine nation-states, of which Papua New Guinea is the largest, with 70 per cent (4 million), and Niue is the smallest (ca. 2,500 in 1991). There are also three French overseas territories, French Polynesia, New Caledonia, and Wallis and Futuna, and two self-governing states (Niue and the Cook Islands) in free association with New Zealand. In 1994, the population of the islands was 80 per cent indigenous, and all are experiencing a high rate of population growth (2.2 per cent) in 1994. The name 'Oceania' was popularized in the 1840s by French geographers after the early French explorer, Jules Dumont d'Urville, to designate the three islands groups – that is, Melanesia (Black Islands), which stretches from New Guinea, Palau and the Marianas on the west to Fiji in the east; Micronesia (Little Islands), a string extending north of Melanesia and west of Polynesia; and Polynesia (many islands), reaching from Hawaii in the north to New Zealand and Easter Islands in the South.[2] Australasia, which variously has also meant Australia (with or without Tasmania) or Australia and New Zealand, is considered geographically and culturally separate.[3] Both will be discussed in this chapter.

Archaeological evidence indicating successive waves of human migration east and south – from the Indonesian archipelago to Australia and New Guinea, upwards of 60,000 years ago, and to the islands of the Pacific in the last 5,000 years – continues to be the subject of intense scientific debate. These cultural migrations brought many plants and animals new to the region, so beginning the long history of the Pacific as a 'laboratory' for human experimentation. The Austronesian family comprises between 600 and 1,500 languages, spoken from Malaysia to Philippines, to which must be added more than 800 languages in Papua New Guinea (PNG), so the region became a fertile area for European anthropological and linguistic research. Melanesia today has approximately 1,000 languages, and the other two groups have 100 more.[4] The region's diversity is emphasized

by its isolation and difficulty of access. The mountainous parts of PNG were daunting to European explorers in the nineteenth century, and remain almost impenetrable to outsiders today, while many islands in the central Pacific are visited by few creatures other than migratory birds.

## EUROPEAN EXPLORATION AND COLONIZATION

The European presence in the Pacific began in 1513, with Spanish sightings of the Pacific, and with Magellan's voyage in 1521. East of Timor, Spain consolidated its empire in the North Pacific, while in the south, Portuguese and Dutch explorers traced the outlines of New Holland. But it was not until the eighteenth century that Europeans made their presence felt among the indigenous inhabitants of the 'south seas'. Between 1760 and 1810, French and English navigators, including Louis Bougainville and James Cook, systematically charted and surveyed the southern ocean, New Zealand, and the eastern and southern coastlines of Australia. European navigation was accompanied and made possible by the nautical applications of science and systematic cartography, and celebrated in the collection of data, artefacts, and specimens of flora and fauna – 'tools of empire' that contributed to educated Europe's map of the world.[5]

European collectors established the Pacific as a paradise of natural diversity, and following the experiences of Cook and Sir Joseph Banks, there were repeated private, naval and government expeditions.[6] But if Western science gained vastly from its contact with the Pacific, indigenous cultures preceded European contact with a range of local knowledge systems, which comprehended natural history, celebrated formalized art and sculpture, inspired mathematically patterned basketry, intricate weaving and adaptive architecture, and called upon an extensive knowledge of weather, currents and winds in the practice of inter-island travel and trade. Measures of time were applied to agriculture and fishing, while experience brought a range of local knowledge of soils and vegetation, fauna, topography, and the medicinal uses of plants. Polynesians are masters of wood and stone carving, Melanesians are known for their elaborate totemic art, and Micronesians, for their functional use of natural materials. Australian Aborigines have developed complex belief systems and a highly adaptive understanding of local ecology and environmental management. In the twentieth century, these have become reservoirs of cultural and artistic inspiration for Europeans and indigenous peoples alike.

European colonization brought new languages, particularly English and French, to Oceania, as well as a range of customs, employment practices – and diseases – unfamiliar to native peoples. From the nineteenth century, contact not infrequently produced a 'fatal impact' in the form of death, depopulation and dislocation of traditional village life.[7] Private and government-sponsored expeditions led to overseas knowledge of places and peoples, while colonial administrators documented flora, fauna and mineral resources. Europeans established cities, including Papeete, Suva and Vila, which attracted rural labour and disrupted community lifestyles. 'Balance', it is said, disappeared from traditional village-based cultures.[8] From the early nineteenth century, education was largely in the hands of missionaries, and there was little higher education until after the Second

World War. Literacy rates rose higher in some countries (notably Fiji) than in others, but remain challenging. In Papua New Guinea, two universities were established before independence, but elsewhere, university remains a luxury. Throughout the islands there survives a rich cultural heritage which, if at first viewed unsympathetically by missionaries and officials, in now seen as a special part of the common heritage of humankind.

In Australia, European engagement took different forms. Australia has been described as Europe's geographic 'unconscious', a place of imagined mystery and fantasy, whose native populations were reluctant to deal with Europeans and spoke of their origins in a distant Dreamtime.[9] Darwin found the continent a 'land of contrarieties', and so it remained. Although, from 1788, New South Wales and Tasmania were founded as penal settlements, the antipodean colonies actually served a wide range of British naval, strategic and commercial interests throughout the region. Free immigration to what became Victoria, South Australia and Western Australia conveyed different traditions of settlement. Overall, the European presence, in the words of a noted historian, was 'born to the age of science' and the history of the continent embraced the zealous pursuit and application of science and technology, the observation and recording of nature, and the inventory of natural phenomena.[10]

Like the Pacific islands, Australasia was of interest to European science became of its exotic and unusual flora and fauna, which attracted collectors and afforded specimens to metropolitan museums, zoos, and botanical gardens, and for a position from which to observe the southern skies.[11] Systematic exploration of the region was vital to the resolution of geographical, geological and morphological controversies that had raged for centuries, and for completing and cataloguing the 'map' of the discoverable world. European science drew heavily upon its rich and unusual flora and fauna, and the field sciences, including the sciences of man. The Pacific was drawn into readings of social Darwinism, mirrored in late-nineteenth- and twentieth- century colonial (so-called 'white Australia') policies towards immigration, with their restrictive measures against non-British and non-European (including Aboriginal) peoples.[12]

Both in Australia and New Zealand – where free white settlements followed lines of careful policy – scientific culture emerged more as a cultural given than as an object of policy. Despite the 'tyrannies of distance' from Europe, scientific controversies reflected debates current in Britain and North America.[13] From the beginnings of civic life, and responsible government in the 1840s, colonial legislatures devoted resources to public museums, and to both public and private education, and colonial capitals vied with each other for primacy and participation in intercolonial and international exhibitions. Patterns of colonial scientific enterprise were similar to those found in Britain's earlier 'settler colonies' in North America and colonial institutions in British India – including the exchange of specimens and artefacts, the establishment of local learned societies and journals, and the creation of professional associations – while patronage and reward systems flowed from the institutions of Britain.[14]

Not surprisingly, the cultural world of the colonial capitals of Australia and New Zealand were constructed as similar, if smaller, versions of the leading provincial towns

and cities of the metropolis.[15] In Australia, the first university (of Sydney) was established as a self-conscious adaptation of English traditions, in 1851; and was followed by universities in Melbourne and Queensland; there were four by the turn of the century (and 35 today). Scientific cooperation prompted closer association within New Zealand, among the six colonies of Australia, and across the Tasmania Sea. In New Zealand, the first university was established in 1869 at Otago, and there are now over twenty, together with a sophisticated infrastructure of research institutes, many of world standing.

To the colonist, as to the colonizer, natural science held the virtues of utility, and the circumstances of colonial life encouraged practical work in astronomy, analytical chemistry, and in the 'economic' sciences of botany, breeding, and agriculture, geology and mining. Transplanted Britons introduced current theories, methods and techniques in physics and biology to schools, universities and governments practice. But in the context of 'settler capitalism', less public attention was paid to pure research in the mathematical and physical sciences and, judging from the proceedings of colonial learned societies – established from the 1840s to the 1890s – theory often seemed less rewarding than experience. Australians were easily reminded that early explorers had lost their lives pursuing European beliefs and looking for inland lakes that were not there, or finding river systems that were different from any known in Europe, or Africa, or the Americas.[16]

By the beginning of the twentieth century, a view of colonial enterprise sometimes characterized as 'practical idealism' supported a wide range of invention and innovation. The appropriation and acceptance of new technologies, especially American, was widely applauded. But Australians and New Zealanders also showed a flair for improvization and adaptation that constituted a unique form of innovation producing a remarkable technological history of its own. Local innovations such as the iconic 'stump jump plow', the cyanide process for the extraction of gold, and sea-going refrigeration tended to celebrate practical creativity, and as such were welcomed by the pastoral, mining and agricultural communities.[17] From the gold rushes of the 1850s, if not before, 'Yankee notions' that eased the circumstances of domestic life in the cities or in the bush were assimilated more rapidly than goods from Britain, but active imitation of American industrial manufacturing styles and processes awaited the early twentieth century. Imperial policy ensured that the Dominions, like India, remained primary producers for Britain's industries and markets for her manufactured goods. Economic dependence on overseas investment, and on the primary industries of wheat, wool and minerals, continued to shape Australian life until well after the Second World War. Much the same was true of New Zealand, with its far smaller population and smaller industrial base. Invention and innovation grew from a tradition of importation and adaptation for domestic use, as with the colonial railways, rather than for export.[18]

The early years of this century, which saw the creation of the federated Commonwealth of Australia (1901), saw growing Australian and New Zealand interest in science for its practical value in agriculture – including weather forecasting, crop and soil improvements, and irrigation – and in certain aspects of manufacturing. The First World War – in which Australians and New Zealanders served with Britain's imperial forces in the Pacific, Europe and the Middle East – presented serious economic challenges to both countries. As in Britain, both established new government agencies – the DSIR in Britain and New Zealand, the CSIR in Australia – for the promotion of scientific and industrial research.[19] Through the interwar years, these agencies, together with the universities, placed research in the agricultural and Earth sciences on a firm foundation, and saw their increasing practical application in economic terms. Science (and to an extent, invention) slowly acquired a sense of 'place', a sense that certain laboratory techniques, choices of problem, research strategies and ways of thinking were recognizably 'Australian' or 'New Zealander'. Nonetheless, both countries continued to rely heavily upon British research traditions, and typically sent their best graduates (Lord Rutherford is an outstanding, but not unique, example) 'home' for research training. In the process, both countries lost some of their most able people who, once abroad, would never return.

Through the interwar years, science and technology had a popular following, but given the fact of small domestic markets, imperial preference and tariff walls acted to discourage local innovation and export. The truncated evolution of the Australian motor car industry became a case in point – an excellent machine could not be made profitable in a small market where inexpensive imports could easily seize hold. The consequences of the enormous losses of skilled manpower during the First World War, coupled with dependence on British capital and the effects of the Great Depression, made the 1930s a time of great difficulty for industrial development. Under the circumstances, the establishment of a fundamental research base, and an infrastructure for technological innovation, was long deferred.

## CONSEQUENCES OF THE SECOND WORLD WAR

The Second World War brought many changes to Oceania, Australia and New Zealand, many of which influenced post-war political and cultural events. From September 1939, distant events in Europe had immediate consequences for its colonial possessions in the Pacific. After the fall of France, Noumea and Tahiti installed the Free French Government, and Polynesians were among the Pacific Battalion that fought in the Middle East from 1941. Australia and New Zealand sent men to Britain and a Maori battalion saw service in Greece. At the end of the First World War, Australia had become a surrogate power in the administration of mandates created by the League of Nations for former German possessions in Papua and New Guinea, and Japan had replaced Germany in Micronesia. Now both rushed men to their colonies' defence. Following Pearl Harbor, and the fall of Singapore, the rapid Japanese advance forced heavy fighting on both land and sea, in which the Allies met defeat along a line stretching from Papua to the Solomons, and into the central Pacific.

As Japan occupied the phosphate islands of Nauru and Banaba, and the Gilbert and Ellice islands, native peoples were brought into the front lines as conscripted labour, and suffered appallingly. In PNG, villagers conscripted by the Australians, as one historian has put it, carried the war on their backs. Elsewhere, evacuations dislocated or destroyed whole communities and cultures. Fighting on their own against a powerful invader, when European administrators

had abandoned them, created a new sense of purpose and dignity among islanders, notably in PNG, Fiji and the Solomons, and made impossible any easy return to pre-war, colonial mentalities.[20]

While Australia and New Zealand were never invaded, Darwin suffered heavy and repeated bombardments, while all Australians, experiencing submarine attacks along the coast, feared a planned Japanese invasion, and the country withdrew what troops it could from Europe to make what many saw as an inevitable stand. Following Allied victories in the Coral Sea, and later at Midway, however, the Japanese threat was diminished, and then disappeared, and Australians fought their way back into Papua New Guinea. At home, national independence in economic and industrial affairs, viewed as a momentary exigency during the First World War, became a prominent question during the Second. Australians and New Zealanders, cut off from traditional British manufactures, were now obliged to make good their own, in industries ranging from shipbuilding to aircraft engines. Following the collapse of British power in Singapore in 1942, both Dominions looked to the United States as their principal defender. Between 1941 and 1945, the transit of over three million American troops, with their vast logistic trains, made a lasting impression, and drew Australia, in particular, far closer into the American strategic orbit than ever before, with lasting consequences for post-war attitudes and policy.

The sudden arrival of American forces also transformed life in many of the pacific islands, which became staging posts for the island-hopping counter-attack against Japan. In New Caledonia and the British colonial islands, Americans built a new world of Quonset huts and airfields, tinned food and armoured cars, money and social relationships that symbolically and in practice appealed to the Pacific tradition of gift and exchange. In New Guinea, Melanesian cargo cults assimilated this miraculous wealth within traditional frameworks of religions ritual, in the process contradicting missionary and administrative teachings. As a consequence, the war fortified local traditions, undermined colonial policies, introduced new ideas, ended the myth of European (and Japanese) supremacy, and brought islanders into contact with outsiders. Anti-colonial sentiment grew as assumptions about the permanence and invulnerability of the colonial order collapsed. After the war, Australia assumed a larger role in the region, in the administration of Papua New Guinea, while the British, French and Americans remained in the islands of the central Pacific. The war was a turning point in the history of colonial rule, but its consequences were not to prove as sudden, or as extreme, or as ideological in their character, as those that almost immediately took hold in Africa, India and Southeast Asia. The 'Pacific way', as it would be called, apparently required a different path to independence and development.

In Australia and New Zealand, post-war reconstruction encouraged the development of manufacturing industries and the exploitation of natural resources and trade in natural products. At the end of the war, the populations of both countries were over 90 per cent British by birth. To acquire the labour force needed to build huge projects such as the Snowy Mountains hydroelectric and water scheme, immigration quotas were expanded, and when sufficient British migrants did not come, waves of southern Europeans did. In ways not seen since the gold rushes of the nineteenth century, Australia began to experience the reality of multiculturalism. In the mid-1950s the Federal Government set out to improve facilities at the impoverished, pre-war universities and to strengthen the research base at CSIRO establishments, while in Canberra, an Institute of Advanced Study and research schools were established at the Australian National university to lure distinguished expatriate Australian scientists and social scientists back 'home' and to increase Australia's knowledge of its Pacific neighbours – including Papua New Guinea, whose administration Australia had acquired.[21]

During the 1950s, breakthroughs in soil science, genetics, and irrigation technologies – many of Australian origin – enabled a rapid expansion of agricultural industries, while the wool industries looked for new markets. Driven by new technologies of exploration, and vast private enterprise, a new wave of mineral booms, beginning in the 1950s, continued well into the 1970s. Australia became known, somewhat ironically, as the 'lucky country', and through the 1960s and early 1970s its population enjoyed an enviable standard of living.[22] Continuing a tradition of exploration begun by British and Australian expeditions before the First World War, Australians contributed substantially to the International Geophysical Year in 1957, and to the regime established by the Antarctic Treaty of 1959, which provided for the scientific study of the Antarctic landmass and the southern oceans. The Australian Antarctic Territory, which was transferred to Australia by Britain, and is administered from Canberra, includes almost a third of the 'last continent', and an area almost as large as Australia itself. Over the last twenty-five years, New Zealand has also played a key role in Antarctic Treaty discussions, particularly concerning proposals to exploit the region's marine and mineral resources. Both countries maintain establishments there, which have been models of international cooperation with the former Soviet Union and other treaty signatories.

In the 1950s, following Britain, both Australia and New Zealand courted the prospect of limitless power from nuclear plants, and in the 1960s, Australia participated, often as a proxy for American interests, in some of the more bizarre nuclear projects envisaged by president Eisenhower's 'Atoms for Peace' plan and Project Plowshare. New Zealand, whose energy needs were met by other sources, soon left the nuclear picture, but Australia's nuclear development led to the installation of two research reactors, and a proposed nuclear power plant on the eastern coast, south of Sydney. In the early 1970s, faced by the uneconomic cost of nuclear electricity, given existing alternatives of coal and hydro-power, Australia declined to embark upon nuclear power, and after much criticized delay, signed and ratified its participation in the Nuclear Non-Proliferation Treaty.[23] During the 1980s, Australia played an important role in the work of the International Atomic Energy Agency in Vienna, and has acted as a regional moderator in discussions of the increasing use of nuclear power in the Asia-Pacific region.

## THE POST-COLONIAL PRESENT

The writing of history necessarily reflects the assumptions of its time. In the twentieth century, Oceania and Australasia have been studied from several different perspectives. The emphasis on discovery, exploration, and colonial encounters

that dominated the literature between 1900 and 1939, has gradually given way to a literature of introspection, comparison, and respect for indigenous 'voices'. With decolonization in the 1960s and 1970s came a newer history, emphasizing regional development and the role of the Pacific in a new internationalism, but within a world still dominated by superpower rivalries (Map 20). A growing interest in cultural unities in the 1980s, has given way in the 1990s to a recognition of the region's many 'separatenesses'. The administrative and linguistic unities imposed from outside masked the consequences of colonial rule for European culture.[24] As the 'master narrative' of colonial rule has fractured, once-easy divisions between pre-colonial, colonial and post-colonial developments are now being set aside in favour of local narratives, in which peoples, places, and cultural identities command greater attention. Historians who once wrote from the standpoint of relations with the imperial powers, now speak of much more complex processes of 'engagement' and self-definition. With this has come recognition that the region's supposed transition from a colonial past to a post-war, post-colonial future has been anything but smooth. Arguably, the present began with the

political coups in Fiji in 1987.[25] Places in the Pacific once thought paradisiacal no longer seemed securely so.

Nothing quite so dramatic as a coup has threatened Australia, but constitutional relations with Britain, traditionally close – and notably so during a long period of Liberal and Coalition party rule between 1945 and 1972 – were frayed in 1975, when the elected government was forced to resign by the representative of the Crown. When Britain entered the European Common Market, both Australia and New Zealand were obliged to review their economic and political positions, which has had far-reaching consequences for public and institutional practices. While educational, family and trade links remain strong, loyalties to the monarchy have much attenuated within the last decade; and many now find it ironic that the Queen of England should be Australia's Head of State. There is talk that Australia will eventually proclaim itself a republic, albeit one within the Commonwealth. Whatever the case, successive Australian governments have stressed continuity in their role in the Western alliance. After the war, Australia's defence policy – which had always relied upon the participation of its 'great and powerful friends' – turned increasingly towards cooperative agreements with the

United States. These were first codified in the ANZUS Treaty in 1951, and later exemplified by its presence in the conflicts in Korea, Viet Nam (Australia was the only country to side militarily with the US in that conflict), and the Gulf War. While New Zealand has shown fewer signs of incipient republicanism, it has asserted a powerful sense of national self-reliance, reflected in a series of austere economic policies, and in its rejection of American nuclear ship visits. Both Australia and New Zealand, along with most of Oceania, have taken up outspoken positions against the continuation of French nuclear tests – the last series of which, in 1995, served to remind inhabitants that the region still remains a laboratory for Europe.

During the last twenty years, both Australian and New Zealand governments have taken major steps to redress centuries of mistreatment and neglect of their indigenous peoples. In 1967, Australian Aborigines, who comprise about 1.5 per cent of the Australian population, were at last invited to share in the symbols and privileges of citizenship; and through the 1980s, increasing (but, so far, inadequate) attention was paid to persisting and difficult problems of Aboriginal health and welfare.[26] In 1992, an historic decision of the High Court of Australia opened the way for the determination of native title in land rights, and negotiations since promise new possibilities for compensation, although not without a legal struggle. Earlier, nation-wide preparations for the bicentennial of European settlement (or 'invasion', as some prefer) in 1988 drew attention to changing cultural identities in Australia, and the importance of Australia's role in the Asia-Pacific region. As Japan and the Republic of Korea emerged as major trading partners, so both countries reviewed their economic, diplomatic and defence links with the United States and Britain. Within the last ten years, what it means to be 'Australian' in an increasingly multicultural society has been a recurrent topic of historical and popular debate. Emerging self-definitions have encouraged a new tolerance and respect for women and minorities. In New Zealand, where British traditions have been perhaps slower to fade, biculturalism has progressed beyond mere lip service to treaty obligations, and is now enshrined in the educational and cultural life of the country. It is expected that *pakehas* (i.e. persons of European descent) will be taught Maori in primary school.

Today, the many different peoples of Oceania seem united only in wishing for political identity and economic independence, and are deeply divided on the ways and means of achieving either. If a complex colonial history underscores the region's past, so it frames its present. Europe (notably France) continues to express an interest in its future, as does the United States, but it is likely that Japan, which helped initiate the concept of a Pacific Basin community, will play an increasingly dominant role in its management. But in many islands, neither political nor educational systems, nor communal relations, nor concepts of ownership exist which Western science-based enterprises could be built upon; even while much effort is devoted to attempts to diversify the economic base by improving agriculture and mineral resources for export to other countries on the Pacific Rim.

The scientific and economic future of Oceania depends to a considerable extent upon the settlement of unresolved political tensions, which in turn reflect the different traditions of the three large cultural groups and their many ethnic divisions. In 1947, by the so-called 'Canberra Agreement', the former Allied governments with colonies in the region established the South Pacific Commission to ensure social and economic stability of what promised then to be a turbulent region. Gradually, between 1960 and the 1980s, the five-country membership of the Commission was enlarged to include 22 of the island nations and territories, in which the Commission, with its headquarters in Noumea, has sought new ways of implementing appropriate technology in agriculture and marine resources, while cultivating community health, rural development, women's programmes, and community education. However, its current budget is only about $22 million, and falls far short of what is needed.

Until 1962, all the islands had some form of colonial or protected status, and used borrowed forms of colonial rule, except for Tonga and Western Samoa, which retained monarchies and aristocratic forms of government. Today, ten of the islands are independent countries,[27] nine are trust territories,[28] while three others form part of the Trust Territory of the Pacific Islands,[29] technically under United Nations Control but actually administered by the United States. Five of the countries are members of the United Nations, and nine are members of the (former British) Commonwealth. New Caledonia, French Polynesia and Wallis and Futuna are seeking political independence. American Samoa, Guam, the Commonwealth of Northern Marianas and Belau have retained their dependency status with the United States, while Niue, the Cook Islands, the Marshalls and the Federated States of Micronesia have entered 'free association' agreements with their former colonial powers (the latter two, with the United States).

All four are members of the South Pacific Forum, set up in 1969 to encourage regional cooperation as an avenue to prosperity and collective influence. This presently includes 14 countries of Oceania plus Australia and New Zealand, and acts as a caucus on regional issues. Perhaps its most noticeable success has been its institutionalized opposition to nuclear testing, the traffic in nuclear weapons, and the dumping of radioactive wastes within the South Pacific Nuclear Free Zone, created by the Treaty of Rarotonga in 1985. The Forum's regional bodies include the Forum Fisheries Agency, the Pacific Forum Line (to provide a reliable shipping service in the region), and the South Pacific Regional Environmental Program (for environmental protection). These have pursued cooperation policies to regulate drag-net fishing, and to study the effects of global warming upon low-lying atolls. Such measures are valuable, but whether they create a climate for the popular understanding of science is at best debatable. Science policies in the region have included many attempts on the part of UNESCO and other agencies. Papua New Guinea has had a government science policy apparatus since 1975. But 'Pacific science' remains a field of study dominated by the nations and scholars of Europe and the Rim;[30] and international recognition that there is also a science 'of the Pacific Island peoples', which can embrace local as well as Western practices, is a much more recent development.[31]

Generalizations are difficult, but all the islands can be considered 'Third World' countries, with wide discrepancies in local wealth, political instability, and threats to civil order. Almost all the islands have, since the 1970s, faced increasing pressures from ethnic and democracy movements. In Vanuatu, there is a volatile peace, in Fiji, a recent history of military coups and ethnic strife, and in Papua New Guinea, a

simmering rebellion. Many Micronesians live in towns, but most Oceania islanders are rural dwellers, whose economy is based upon primary agriculture and marine resources. The per capita GDP of the thirteen islands varies from the relative wealth of Fiji, with $1,182, to Kiribati, with only $271. Inter-island trade is very small, while earnings from traditional plantation commodities (sugar, coffee, copra, etc.) have largely disappeared. Some look favourably upon the experience of Indian Ocean and Caribbean countries, as examples of what small island states can achieve. Others are less optimistic.[32]

The distribution of natural resources varies widely, and while marine resources are relatively abundant in some of the 200-mile Economic Exclusion Zones established in the 1970s – a development that may well have enormous implications for regional development – others have little.[33] In terrestrial resources, Papua New Guinea and Fiji are relatively well endowed, while the atolls of Kiribati and Tuvalu, at the other end of the spectrum, are not. Papua New Guinea boasts three forms of secondary industry – resource processing to convert raw materials (such as coffee, tea, timber, copra and cocoa) into consumer process; small-scale industries, such as motor vehicle repair and soft drink manufacture that are by-products of urban life, and service industries. There has been little opportunity for heavy industry to be built, owned or operated by local entrepreneurs. In 1994, 70 per cent of secondary industry in Papua New Guinea was foreign owned (88 per cent of which was Australian); while the small proportion (c. 10 per cent) of the secondary industry workforce that was expatriate received 50 per cent of industrial wages. It is hoped that the country's huge mineral wealth in Bougainville, when fully exploited, will be processed, with a view to producing 'value added' before export, as well as profitable subsidiary industries. The 'value added' process, which took years to introduce in the far more technologically sophisticated mining industries of Australia, may take more to complete in Papua New Guinea.

The applications of science and technology, once thought as a tool kit of possible solutions to the problems of underdevelopment, seem now far more problematic in their ownership and use. The role of science and technology in economic survival is linked to political change, and to an increased participation in international trade.[34] Island aspirations are high, but infrastructures are unsteady. The restraining effects of small overseas markets are compounded by high imports, producing systemic deficits. For most islands, a recipe for economic survival relies heavily upon fishing, international agreements, overseas aid (a fifth of Australia's aid budget goes to Papua New Guinea), investment (notably from Japan and the European Union), and tourism. In the immediate future, tourism more than trade – and both more visibly than scientific research or development – are likely to define the political economy and culture of the smaller islands, while in the larger, the interests of multinational mining companies, often involving high capital-intensive technologies, have become, and will probably remain, sources both of wealth and political resentment. Emigration to North America, Australia, or other wealthier climes – there are three times as many Niueans who live in New Zealand as in Niue – has had an important impact, in which it is difficult to weigh the value of remitted earnings against the loss of talent.[35]

In this context, Western science has brought important changes, but few revolutions. In a region almost entirely post-colonial, science and technology play an essential part in everyday life, but the systems are paid for and built by external aid and expertise. The conservation of wildlife and resources, the recognition of communal ownership, and the careful monitoring of 'eco-tourism' all require concerted efforts among the islands and their regional agencies, lest they disadvantage the environment and its inhabitants. Advanced technologies of communication and transportation have replaced traditional forms, but Western and Japanese investment and commercial fishing practices threaten, as well as benefit, the interests of local populations. If there is one area where there is growing solidarity, it is against the use of the Pacific as a testing ground. For many years, islands that formed part of British and American nuclear and missile testing facilities drew economic benefit from that connection. Now that nuclear testing has ended, islands held under special agreements by the great Powers, including the Phoenix group, will be obliged to seek other solutions. For one – Johnston Island – a solution is clear, as it remains one of America's six depositories of chemical weapons, and forms part of current plans to incinerate such weapons from the American arsenal. For the region in general, given that traditional agricultural export prices continue to fall, experts recommend more attention to private sector enterprise – inevitably linked, as always, to international expertise and overseas investment.

The 'plight' of the Pacific and its islands lies in profound contrast to the prosperity of Australia and Aotearoa/New Zealand. Today, Australia (pop. 17 million) and New Zealand (pop. 5 million) are the Pacific's regional powers, and are world leaders in the arts, sciences, and literature. Both have extensive relations with their Oceanic neighbours, as with Asia, the Americas and Europe, and both are drawn increasingly together in economic and defence cooperation. In Australia and New Zealand, the techno-scientific infrastructure is resilient, but its support is the subject of recurrent debate. Australia has over 600,000 students in higher education, and spends annually 1.6 per cent of its GNP (1992–93) on research and development. Its scientists contribute about 2.1 per cent of the world's scientific literature, above the country's proportional research spending. Australian research spending in 1992 was the second-highest rate level of involvement with the public sector. Within the OECD, Australia's ratio of scientists and engineers to its labour force is 50 – above the median of 45, and higher than that of other Asia-Pacific countries, although far below Japan (75) and the United States (76).[36]

Science is no longer 'colonial' in either country, although both are 'interdependent' on the dominant economies, particularly the USA and the European Union, for much of their collaborative effort. Recent efforts to focus resources on a smaller selection of fields in which they can 'compete' have led to considerable debate in both concerning 'concentration' vs. 'balance' in research and infrastructure. In both cases, there has also been considerable effort – in Australia, by modifications within the research-intensive CSIRO, and in New Zealand, in the dismemberment of DSIR – to link basic research to industrial goals and social and economic outcomes. New Zealand has restructured its science agencies into ten Crown Research Institutes (CRIs), to produce knowledge of relevance to industry, but also to ensure that Maori interests are served. Today, there appear to be no Maori scientists, using Western definitions, and projects proposed by Maoris to the Public Good Science Fund are few, but as CRI scientists and Maoris engage with

one another, there is potential for new models of associating science and technology with the expressed interests of indigenous peoples.[37]

Given the sheer diversity of the region, Western scientific culture has been unevenly experienced. For the same reason, the educational impact of science is difficult to measure. The University of the South Pacific, established in 1968, has several regional campuses in which science is taught; and the francophone Pacific is strengthening provision for science in higher education in French Polynesia and New Caledonia. In Oceania, it is clear that science and technology, while holding much potential for marine development, have not been the salvation of the islands; on the contrary, in some ways, as elsewhere in the world where modern science has confronted indigenous systems, technology transfers have had the usual two-edged effect of creating employment and expanding horizons, while threatening traditional values and established cultures. Basic facilities are limited. For example, Tonga spends 13 per cent of its national budget on health, but with a population of fewer than 100,000 people, this represents only $28 per person, which has to cover health education as well as medical care. It is not surprising that Tongans still debate AIDS more as a question of morality than as a disease.[38]

Researchers repeatedly demand public health measures to counter water-borne diseases that are by now unfamiliar in the West.[39] Nutritional shortages linked to the consumption of processed foods are contributing to 'diseases of affluence, without the affluence'.[40] Global environmental problems are endangering the coral reefs and islands, threatening the health of local populations historically dependent on sea food, and causing concern throughout the world.[41] Claims and counter-claims cloud the environmental consequences of the French nuclear tests since 1966 on the Taumotu atoll of Mururoa, 1,250 km south-southeast of Tahiti, but it is clear that the matter is affecting not only international public opinion, and island nationalism, but also the tourist trade from which France (and Polynesia) had hoped so much.[42]

Meanwhile, from American Samoa, come reports of a boom in personal computers, producing new possibilities for networking and exchange of ideas. As deep-sea mining becomes more economical, the oceans may offer new opportunities for technology, but the extent to which islanders will reap the profits of such activity remains to be seen. Meanwhile, the phosphate industry on Nauru, and the ecology of Nauru itself, is nearly exhausted, while the environmental consequences of high-tech mining in Bougainville are hotly contested. The means of achieving sustainable development is high on the agenda of the South Pacific Forum, and of United Nations agencies with missions in the region. But there is little mention of Oceania in the planning documents of APEC, which focuses more upon Australia's participating in the expanding Asia-Pacific market. Current policies towards Oceania risk becoming nothing more than another phase in the developmental colonialism that has characterized the history of the region.[43]

## RETROSPECT AND PROSPECT

'Oceania' and the 'Pacific' are names given by Europeans to a region that Europeans first invented, later colonized, and still effectively control. Through three phases of Western influence – 200 years of Spain, 150 years of Britain and France, and 50 of the United States – its vast spaces are invested with meanings that others have imparted to it, but whose complexities are still largely unrecognized outside the region.[44] There is no dearth of Pacific scholarship. On the contrary, there are at least twelve major English-language journals devoted to Pacific questions in the fields of politics, economics, geography, anthropology and science; and many others – edited in Russia, France, Germany, the Republic of Korea and Japan – publish studies of the region.[45] From the diversities of the region, Europeans have collected and codified metropolitan 'museum cultures' of languages, art, artefacts, and natural products. Its islands and seas have served as quarry, plantation, farm, and site of rival religions and cultural 'civilizing missions'. Despite protests, it remains a laboratory space in which two countries used to explode nuclear devices, and a third still does, and where, until recently, three countries tested missiles. Its history has seen four centuries of Western science and culture, and a history of acceptance, assimilation, modification and rejection. But while science may help us understand the region, it is less certain to change it.

That change may, or must, come from the indigenous peoples themselves. From traditional cultures and languages 'outsiders' and settlers have still much to learn. Now, as in the eighteenth century, Western 'experts' may return home better informed about tropical agriculture and marine life from talking with Melanesian farmers and Micronesian fishermen, than from their science-based university seminars.[46] Domains of natural knowledge previously dismissed as merely 'ethnoscience' are beginning to receive belated recognition.[47] Increasingly, attention to traditional, 'holistic', farming and fishing practices – whether as an antidote to modern life, or in accommodation with modern techniques – has suggested ways of improving the health and nutrition of islanders who are otherwise impaired by Western diets. Finance to enable the individual or community development of successful traditional practices, rather than their mere replacement by technologies transferred from elsewhere, may give an impetus to local innovation.[48] The contribution that such practices may make to 'sustainable development', now widely canvassed by the United States, as well as regional conferences, must hold part of the answer for the post-colonial Pacific.[49]

In an age of declining aid budgets, regional assistance is uneven. Few, if any, Australian universities are conducting research on 'alternative' technologies that may be used in island development, or into the Western scientific basis of alternative medical strategies as used in the islands. By contrast, most large, publicly funded Australian museums now have Aboriginal curators and educators, and the proposed National Museum of Australia in Canberra will give Aboriginal histories, oral traditions and ways of knowing a central place among its three component spaces. In New Zealand, the new National Museum now under construction in Wellington is to be centred around Maori history and the experience of biculturalism. As such, whether it will complement concepts in Maori, or Maori science, remains to be seen.

All such developments are contested, and many remain problematic. From South Africa to India, the experience of 'Third World' countries has shown that high tech and traditional methods can usefully coexist. Primary and

secondary education in such countries can usefully learn from the history of local, rather than foreign, ways of transmitting scientific ideas – out-of-school knowledge can be privileged, instead of resisted, while local languages can be employed to assist the communication of concepts describing natural objects and processes.[50] From the mixed legacies of the West, the peoples of Oceania have contrived 'evolving amalgams', new indigenous cultures, which absorb the power of science and technology, while challenging its dominance in every walk of life.[51] Direct satellite access to television for science and cultural education is a present and expanding reality throughout the region; it remains to be seen what uses are made of it, and what philosophy will govern its regional programming. Meanwhile, from island societies where young people are taught knowledge of nature along with a respect for ecological practices, there is much the West can learn.[52] An understanding of science and its practices as an ethical system – as well as a model of the world, and a search for objective, reproducible knowledge following discoverable universal laws – may be among the greatest, if so far unrealized, benefits of this engagement.

At the turn of the millennium, Australia and New Zealand are small, highly developed cosmopolitan societies, securing access to the expanding markets of Asia while sustaining ties of culture and community with the Americas and Europe. At the same time, both envisage a role – what a recent Australian foreign minister, Gareth Evans, called 'constructive commitment' – in Oceania, a region that remains otherwise burdened with the legacies of underdevelopment, political and ethnic unrest, poor literacy, and economic dependence.[53] No one believes that remedies are easy.[54] Some argue that the islands should be spared further Western intrusion; others seek workable adaptations. Increasingly, the recognition and apportionment of intellectual property rights in so-called 'closed' traditional knowledge systems and techniques is becoming an important issue in international law, with potential consequences for island cultures and economies. Elsewhere, significant structural readjustments that might lead to a fast-growing export base, linked to the 'new Asia', are possible, but history suggests how difficult they will be to achieve.[55] The region has been cast bravely into the script of the new 'Pacific Century', but for the foreseeable future, it seems questionable whether Oceania – or Australasia – will be more than a minor actor in the great spectacle that will take place in a region dominated by the economic superpowers, and the giants of North Asia.

## NOTES

1.   For an overview of the region, see T. U. Fairbaim et al., *The Pacific Islands: Politics, Economics and International Relations*, Honolulu, 1991

2.   D. Oliver, *Oceania: The Native Cultures of Australia and the Pacific*, Honolulu, 1989, Vols. 1 and 2.

3.   The term 'Oceania' normally excludes the non-tropical Ryukyn and Aleutian islands and the Japanese archipelago, and also excludes Indonesia, the Philippines and Formosa, which are regarded as more closely related to the Asian mainland, and Norfolk Island, which is a territory of Australia. Australasia was once taken to include New Zealand (and will be in this chapter), although this usage is not now politically correct, while of course Tasmania is a state of Australia.

4.   For regional information, see A. Bescher (ed.), *The Pacific Rim Almanac*, New York, 1991; S. Hoadley (ed.), *The South Pacific Foreign Affairs Handbook*, Sydney, 1992; *The World Factbook*, Washington DC, 1993; and the *Macquarie World Atlas*, Canberra, 1994.

5.   Useful introductions to the literature include O. H. K. Spate, 'South Sea to Pacific Ocean: A Note on Nomenclature', *Journal of Pacific History*, Vol. 12, No. 3–4, 1977, pp. 205–11; *The Spanish Lake: The Pacific since Magellan*, Vol. 1, Canberra, 1979; and B. W. Smith, *European Vision and the South Pacific, 1768–1850: A Study in the History of Art and Ideas*, Oxford, 1960, New Haven, 1985.

6.   See N. Thomas, 'Licensed Curiosity: Cook's Pacific Voyages', in: J. Elsner and R. Cardinal (eds), *The Cultures of Collecting*, Melbourne, 1994, pp. 116–36; R. MacLeod and P. F. Rehbock (eds), *Darwin's Laboratory: Evolutionary Theory and Natural History in the Pacific*, Honolulu, 1994.

7.   A. Moorehad, *The Fatal Impact*, London, 1966.

8.   For the extensive literature on Island history in English, it is useful to begin with D. Scarr, including *The History of the Pacific Islands: Kingdoms of the Reefs*, Melbourne, 1990; *Fragments of Empire: A History of the Western Pacific High Commission, 1877–1914*, Canberra, 1967; (with J. W. Davidson), *Pacific Island Portraits*, Canberra, 1970; and *More Pacific Islands Portraits*, Canberra, 1979.

9.   Readers unfamiliar with Australian history could profitably begin with R. White, *Inventing Australia: Images and Identity, 1688–1980*, Sydney, 1981, and continue with the popular, if polemical, R. Hughes, *The Fatal Shore*, New York, 1987.

10.   For introductions to the literature, see R. MacLeod and P. F. Rehbock (eds), *Nature in its Greatest Extent: Themes in the History of Western Science in the Pacific*, Honolulu, 1988; C. Finney, *Paradise, Revealed: Natural History in Nineteenth-century Australia*, Melbourne, 1993.

## AN INTERDEPENDENT WORLD: ACHIEVING PEACE AND SUSTAINABLE DEVELOPMENT THROUGH INTERNATIONAL COOPERATION

*Georges-Henri Dumont*
in collaboration with *Sergei L. Tikhvinsky, Gregorio Weinberg*
and *Tao Wenzhao*

The twentieth century has left the present century a legacy fraught with consequences and concern for the future. The processes of interdependence and globalization were initiated and advanced in all fields of activity; no continent was left untouched, but flagrant inequalities persisted. The century's unprecedented scientific and technological progress affected the everyday lives of people in those countries that had access to such advances.

The example of speed itself is particularly striking. Before the Second World War, express trains travelled at an average speed of 100 to 150 kms per hour. By the end of the century, they were able to attain record speeds of over 250 kms per hour. Although ocean liners hardly increased their average speed beyond 29 to 30 knots, hydrofoils and hovercraft reached speeds of 65 knots, or 110 km per hour. The development of aviation was closely linked to its military applications: after being used in a limited manner in 1914, aviation became decisive in the period from 1939 to 1945. Helicopters could travel no faster than 650 kms per hour, the speed at which the relative velocity at the tips of their propellers approaches the speed of sound. However, jet planes, both military and civilian, largely exceeded that limit: by 1976 the supersonic jet attained a cruising speed of over 2,000 kms per hour. The main obstacle to further progress was the high level of investment and maintenance costs. At the end of the twentieth century, it seemed that while space flights would be able to achieve still greater speeds, this was no longer the case with land, sea or air transport.

Information technology is evolving at an ever-increasing pace. Computers are getting smaller while their capacity is increasing. The Internet now provides all sorts of information in a split second. In industry, robots programmed to carry out essential production processes more quickly are gradually replacing unskilled workers and easing the workload of others.

There has been opposition to the use of industrial robots and office technology in some quarters, but it is clearly no more than a rearguard action in the industrialized countries, where the most it can achieve is assist in transition processes and in the preparation of new employment policies. Another aspect of technology's impact on everyday life was the key role of architects and civil engineers in the construction of bridges and canals and the erection of towering office and apartment blocks.

The revolution in information technology is one of the most remarkable achievements of the twentieth century. It has greatly changed peoples' lifestyles. The widespread use of the technology tremendously facilitates the information flow, business transactions and communication between inhabitants of different countries and continents.

Biologists learned how to manipulate life itself. From 1978 onwards, *in vitro* fertilization was commonplace, and living organisms could be created and genetically modified. Although life scientists identified 19,099 genomes in an Earthworm and 25,000 in a garden weed, they were still unable to explain life. Such developments raised more ethical questions than ever before. Meanwhile, life expectancy for both men and women had continually lengthened – but only in the developed countries.

The exchange of knowledge made possible by the mass media, the development of transport and communication, and the work of curators, archaeologists, ethnographers and translators has enriched all of the world's cultures. For the first time, the cultural heritage of the peoples of Asia, Africa and Latin America became part of the cultural heritage developed by Europeans and North Americans. The level of education of the general population improved, and plans to eliminate illiteracy were drawn up. Despite these achievements, by the end of the century, approximately 30 per cent of the adult population of the planet remained unable to read or write.

Decolonization and national liberation, which became widespread from 1960 onwards, have not reduced the gap between rich and poor, and countries receiving aid are having great difficulty in coping with the increasingly large-scale population movements.

Sports and physical education became widespread. The Olympic Games was relaunched in the late nineteenth century, on the initiative of Pierre de Coubertin, enabling the world's different peoples to compete with one another in a spirit of peace, even if efforts to win medals and break records were tinged with nationalism and sometimes tainted by the use of illicit drugs. New sports, such as hang-gliding, windsurfing and ballooning emerged.

The tremendous development of science and technology had far-reaching effects on the lives of individuals and on the social and economic conditions of modern human existence in general. However, further development of the quality of life and standards of living is threatened by recurring conflicts between, and within, nations. This has contributed to widening the gap between rich and poor countries and also constitutes a threat to the ecological environment.

The world continues to exist in a state of turbulence, despite the end of the Cold War. Regional disturbances, ethnic conflicts and civil wars continue to break out throughout the world. Ideologies dominate the world political scene, and conflicts between different nations have been sparked off by historical, linguistic, cultural and religious issues.

The imbalance of the world's economic growth, creating a large divide between rich and poor countries, has left one-fifth of the world's population in abject poverty, deprived of the benefits of modern technological development. This poverty has not only prevented a large proportion of the world population from enjoying a minimum of comfort, but will, if not remedied, have repercussions on the future development of the rich countries as well. Our world will remain utterly divided as long as this discrepancy between the rich and the poor countries continues to exist.

In the competition for the benefits of economic development, entrepreneurs often seek immediate success with large profit margins and pay little or no attention to the protection or the development of the environment or the replenishment of natural resources. As a result, the ecological environment is rapidly deteriorating. The rain forests are shrinking at a surprising rate and arable land is being dangerously encroached upon by desert. Waste gases and the contamination of water, pollution of all sorts and the rise of global temperatures due to over-consumption of energy pose serious threats to the very existence of life on the Earth (not to mention the nuclear threat).

It is our duty to arrest this perilous march towards disaster by making careful use of the advanced scientific and technological knowledge currently at the disposal of the modern world. The advantages accruing to nations with access to the vastly developed resources of science and technology have made them rich and independent. If they can share this wealth with all the other nations, in a spirit of solidarity, the world will certainly be a better place for all.

An important lesson we have learned from the history of the twentieth century is that, however rich and strong these nations have become through the conquest, subjugation and colonization of poorer nations, history will probably mete out justice to them. A spirit of reconciliation and

cooperation should thus become the guiding principle for dealing with conflict situations.

The development of transport, communication and the mass media enables us to obtain more information more quickly than ever before. Yet, even though the same information systems are used throughout the world, each people will react differently according to its own cultural sensibility. It is thus imperative to advocate a tolerant and rational dialogue between all peoples, emphasizing the need to recognize the dignity of all human beings, regardless of sex, race, colour or political affiliations, and to ensure universal respect and protection for human rights.

One of the characteristics of the twentieth century, and more particularly its final decades, was the decline of widespread world views. It has been said, rightly, that the eighteenth century ended with a worldview that 'ordered' and 'rationalized'. Influenced by the Enlightenment and related currents of thought (e.g. the *Encyclopédie* and in particular d'Alembert's 'Discours préliminaire'), the period's world view was optimistic (Condorcet's embryonic notion of 'progress'). The nineteenth century and the beginning of the twentieth generated a new worldview, which also claimed to 'order' and 'rationalize' (e.g. the influence of the philosophical ideas of Auguste Comte in France and Herbert Spencer in England and the political ideas of emergent socialism and liberalism), and was at the same time 'optimistic' (consolidation of theories developed from 'progress' and the more recent theories of 'evolution'). Yet, by the end of the twentieth century, we found ourselves faced with a sort of ideological and axiological upheaval, which, in part, explains the climate of crisis that characterizes the early twenty-first century. We have no desire to reinstate either the Enlightenment or positivism, and we are well aware of their limitations, simplifications and mechanical approach. Suffice it to say that nowadays we lack a comparable worldview and a moderately satisfactory set of values that is acceptable to the majority of the world's population. One need only think of the twentieth-century explosion of irrational, pessimistic thought, authoritarian and fascist political ideas, and scientific trends based, not always legitimately, on principles of doubt and uncertainty. Two world wars and their consequences seem to support the viewpoints of the pessimists. To complete this very schematic overview, we should mention that a serious crisis weakened one of the last worldviews, Marxism, which claimed to 'organize' reality and to be 'optimistic'. Moreover, a certain pretentiousness brought Marxism dangerously close to dogmatism. Religious organizations have also been grievously scathed by the undermining of many of their doctrines and assumptions, as much by criticism based on nineteenth-century evolutionism as by the century's cosmologies, without forgetting the obvious and complex processes of secularization. Many religious groups therefore appear to have adopted a defensive attitude, attempting to reconcile science and religion; the fanatic fundamentalists, on the other hand, have taken the offensive and adopted aggressive and intolerant positions, like obscurantist philosophers always opposed to developments in science and technology and their implications. We should also note the spurious extrapolation of 'chaos' theories to the social and human sciences from physics and mathematics, and 'post-modernism', which has made it even more difficult to get on with the urgent task of reformulating a worldview. In the spirit of UNESCO, we should bolster all pluralist

movements that help to reconstitute a new worldview capable of offering a more structured understanding of reality and gradually helping us to regain a less pessimistic view of the future (or a more optimistic one, essentially based on some key ideas such as science and culture at the service of humanity and society), and to become more rational, since rationality is under attack from various quarters, some of which have been briefly mentioned above.

A related issue is the crisis surrounding the notion of 'universality', mistakenly identified with Eurocentrism, which is one in a series of ethnocentrisms that have developed in all periods and places. Eurocentrism has distorted the image of the world and hindered a proper understanding of it. The phenomenon diminished throughout the twentieth century, particularly since the Second World War and the subsequent process of decolonization. For a long time, great civilizations and cultures of Asia, Africa and Latin America were often condescendingly referred to as 'classical' or 'peoples without history' while others were ignored altogether, but with the waning of Eurocentrism, they could be reintegrated into history, from which they had been marginalized or excluded by the so-called 'West'. We now have to face the challenge of constructing a new kind of universality, which should be more than a broader form of Eurocentrism and more effective. In doing so, we should bear in mind that this new form will not be definitive; indeed it will always be incomplete and subject to new influences. Perhaps this idea of universality, which is consistent with the spirit of UNESCO, will help to reconstitute the deteriorating world view. The search for such a new world view should take into account the need for dialogue among cultures and the recognition of the equal dignity of human beings. To quote the illustrious Mexican novelist Carlos Fuentes: 'When we exclude, we betray and impoverish ourselves. When we include, we are enriched and find ourselves'. The search for ancient roots and processes shows us that identity is many-faceted and constantly evolving and not written in stone.

Furthermore, it should be stressed that culture is not just past or present; since it embraces creation and promise, it is also future. Culture should encompass science and technology and should dismiss communication media, which are dangerously straying from the cultural values societies have adopted and have even created their own counter values in certain cases. A number of experts, such as Swedish sociologist Peter Berger, believe that culture is essentially an attempt to make sense of the world around us, which is essential in light of the turmoil and crises of the contemporary world.

On the subject of urbanization and industrialization, it is worth pointing out that in the great majority of developing countries, urbanization was, and remains, out of step with industrialization. This phenomenon, as complex as it is spectacular, has brought poverty (and destitution) to the cities, and, until the late twentieth century, poverty had been largely a rural phenomenon. Unlike the first period of industrialization in developed countries and regions, the current phase, arising from the new scientific and technological revolution, is not generating employment. Urban poverty has returned and appears in two different forms according to the areas concerned (developed or developing). However, the end result is the same in both cases: a rise in unemployment and poverty in the cities and,

as its direct and immediate consequence, a decline in the quality of urban life (deteriorating services, environmental pollution, dilapidation of housing and the urban landscape, rising delinquency and drug addiction, etc.). Increased marginality and large-scale unmanageable population movements have revealed new challenges for the labour market (concerning the shortage of qualifications for the constantly evolving working environment) and for culture (integrating into a new environment without losing one's identity, in terms of customs, traditions, values, and so on). These factors can partly explain manifestations of xenophobia and racism.

A world based on cooperation, human rights and preservation of world peace calls for important measures including the adoption of a broader concept of culture. We believe that rather than engaging in the usual sterile discussions on what constitutes popular culture or national culture, it is far more important to give the concept of culture itself some substance. This entails stripping the concept of any restrictions and concentrating on its *integrating function*, an aspect increasingly important in a society threatened by problems of alienation and rootlessness and the resulting loss of collective memory. French sociologist Alain Touraine insists precisely on the role of memory in protecting us from biased and misleading information, which is habitually used to give us a distorted view of reality.

We must also underline the limitations imposed on the knowledge of historical processes by narrow or minority views (e.g. history focusing on men to the detriment of women and Eurocentric history). At the very least, we should aim to make a contribution to history so as to give it the 'identity' sought by French historian Fernand Braudel (1902–1985), which includes all the forgotten protagonists: indigenous peoples, workers, slaves, peasants, social outcasts, not to mention all those regions and countries previously neglected. This will call for new categories of analysis. If this requires any justification, one could cite the concepts of time, space and causality, which are now indispensable for a proper understanding of contemporary society. Moreover, science and technology should play a key role in devising these new categories.

In addition, we should comment on the use and transformation of some key ideas, such as those concerning 'progress' and their association with the past and 'development'. The latter notion, as is well known, evolved rapidly from its initial economic connotation to its current meaning related to human development, or just plain development, pluri-dimensional and dynamic. The ideas of 'change' and 'growth', although less often used, should not be overlooked either.

It is also extremely important to note that education systems face two major challenges in addition to their traditional objectives, the most important of which is to form 'individuals' and not just 'producers', consumers, citizens or spectators. One challenge is the 'explosion of knowledge', and the other results from the increasing (and increasingly diverse) demands society places on education systems.

As far as we know, Earth is the only planet in the universe sustaining a complete living system, and we bear a collective responsibility for protecting it. Our resources are not inexhaustible, and the population explosion places an increasing burden on them. We must control the increase

of the world's population effectively while carefully and efficiently using our resources. The reaction of the biosphere to humanity's abuse is global, despite the origin of the abuse. Development should no longer be pursued at the expense of the environment. The latest findings concerning environmental protection should be applied in a framework of effective international cooperation to resolve various problems currently affecting our land, air and water, in order, for example, to protect the ozone layer, counteract the greenhouse effect, stop soil degradation and desertification, promote biodiversity, decrease vulnerability to natural disasters and reduce the damage they cause. These goals were set by the Kyoto Conference (1997), but the application of the resulting protocol by the states responsible for the largest carbon dioxide emissions still leaves much to be desired.

The conference on sustainable development held in Rio de Janeiro in 1992 (the United Nations Conference on Environment and Development) was attended by the representatives of some 180 countries, who discussed the programme for the twenty-first century proposed by the former Norwegian prime minister, Gro Harlem Brundtland. The conference adopted a declaration on issues concerning the environment and development and various important decisions related to the protection of the environment.

True to the spirit of its founding concept of a culture of peace, UNESCO has never ceased its work for the preservation of peace throughout the world. This mandate was reaffirmed at the international congress on Peace in the Minds of Men held in Côte d'Ivoire in 1989. The concept of a culture of peace was introduced into UNESCO's programme by its General Conference in 1994.

In certain respects, globalization goes hand in hand with interdependence, but because it tends to reduce everything, including cultural values, to a marketable commodity and to disregard social aspects, many intellectual and artistic communities and labour unions have taken position against it. Anti-globalization demonstrations, often violent, have converged on meetings of heads of state, but as the process of globalization seems unstoppable, attention is turning instead to the different ways of managing it.

The greatest challenges now facing humanity involve the numerous threats to its security resulting from international terrorism, the proliferation of weapons of mass destruction, financial crises, and epidemic diseases, such as HIV/AIDS, SARS, Ebola, avian influenza and mad cow. International terrorism seriously threatens people's right to a peaceful life, and the United Nations Security Council has passed several resolutions to combat this scourge. To deal with these threats, closer and more effective cooperation within the international community is extremely necessary, and in this context, the United Nations has a pivotal role to play.

It is disturbing that at the end of the twentieth century – and into the twenty-first – the authority of the United Nations has been undeniably undermined, particularly as regards Article 53 of its charter: 'no enforcement action shall be taken under regional arrangements or by regional agencies without the authorization of the Security Council'. Whereas, in the Gulf War, military action was undertaken with a mandate from the Security Council, in Kosovo, NATO intervened without such a mandate.

In fact, the United Nations is facing a crisis because people's perception of the law is out of step with existing legal instruments. This crisis would be useful if it led to a reform of the Security Council and clarification of the right of members of the United Nations to take action, whether individually or collectively. The institution of a permanent International Criminal Court, created in 1998, to judge war crimes is an important step in the right direction, yet more widespread ratification is required.

Nevertheless, the United Nations system is the linchpin of the legacy passed on to the twenty-first century by the twentieth. Its survival, with the adjustments made necessary by the course of events and changes in attitudes, is essential to stability and development in an increasingly interdependent world.

To meet the challenges the world is now facing, the United Nations needs reform. But the purpose of reform must be to strengthen the organization rather than weaken it, so that it is able to continue to play an essential role in the stability and development of an increasingly interdependent world.

# CHRONOLOGICAL TABLE

| SUB-SAHARAN AFRICA | EUROPE | WEST ASIA, THE MIDDLE EAST AND THE MAGHREB | CENTRAL, SOUTH, SOUTH-EAST ASIA AND OCEANIA |
|---|---|---|---|
| | | 1898 The Fashoda incident. | |
| 1900 First Pan-African Conference, London. | 1900 Sigmund Freud, the father of psychoanalysis, publishes *The Interpretation of Dreams*. Death of Oscar Wilde. | 1900 Mustafa Kamel founds the *al-Liwaa'* daily newspaper in Egypt. | |
| | 1900 Universal Exhibition in Paris. | 1900 Inauguration of the Egyptian Museum in Cairo. | |
| | 1900 Quantum theory proposed by Max Planck. | | |
| | 1900 David Hilbert identifies 23 unsolved mathematical problems. | | |
| | 1901 First ceremony of the Nobel Prizes in Stockholm. | 1901 Iran grants oil concessions to foreign companies. | 1901 The Philippines become US territory following the Philippine-American War. |
| | 1901 Marconi's successful transatlantic communications. | | 1901 Habibullah succeeds his father, Amir Abdul Rahman Khan, to the Afghan throne. |
| | 1901 *Three Sisters*, by Anton Chekhov. | | 1901 Creation of the Commonwealth of Australia. |
| | | | 1901 The Dutch adopt the 'Ethical Policy' in Indonesia. |

# INDEX

# PLATES

*Plate 1* Isaak Brodsky, oil portrait (1930) of Lenin at the Smolny Institute, St Petersburg (conserved at the Historical Museum in Moscow). In 1917, the Russian leader chose the building as Bolshevik headquarters during the October Revolution (Photo © DeA Picture Library).

*Plate 2* Rosa Luxemburg and members of Germany's Independent Socialist Democratic Party. The Polish-German writer and revolutionary founded, with Karl Liebknecht, the Spartacist League, which became the Communist Party of Germany (Photo © DeA Picture Library).

*Plate 3*  On the streets of New York City following the stock market crash of October 1929, a man tries to sell his automobile. The collapse of Wall Street sent shockwaves through the entire world (Photo © Bettmann/Corbis).

*Plate 4*  On 7 December 1941, the Japanese launched a surprise attack on the headquarters of the US Pacific Fleet in Pearl Harbor, Hawaii, killing some 2,400 people, damaging 21 ships and disabling over 300 aircraft. The assault prompted US entry into the Second World War (Photo © Sipa Press).

*Plate 5*  In 1921, the Cossack military commander Reza Khan (*centre*) seized power in Persia (later Iran) in a coup. He was proclaimed Shah in 1925 but was forced to abdicate during the Second World War (Photo © Bettmann/Corbis).

*Plate 6*  Spanish-born artist Pablo Picasso in his studio at Vallauris, France, where he lived from 1948 to 1955 (Photo © DeA Picture Library).

*Plate 7*  The African-American jazz trumpeter Dizzy Gillespie, 1986. Gillespie was one of the leading proponents of bebop, a musical style employing rapid tempos and complex improvisational techniques, developed in the 1940s (Photo © William Coupon).

*Plate 8*  Charlie Chaplin in *Modern Times* (1936), a film critiquing modern working conditions. Set in a large factory, the film depicts Chaplin's celebrated Little Tramp struggling to survive in the advanced, industrialized world (Photo © Bettmann/ Corbis).

*Plate 9*  Greta Garbo in her role as *Mata Hari* (1931). Hollywood owed much of its early success to immigrants like the Swedish-born star and others including Charlie Chaplin, Fritz Lang and Ernst Lubitsch (Photo © Sipa-Press).

*Plate 10* Exterior view of Notre-Dame-du-Haut Chapel, Ronchamp, France, designed by Le Corbusier and begun in 1950. Le Corbusier was one of the most influential pioneers of modern architecture (Photo © Archivo Iconografico, S.A./ Corbis).

*Plate 11* The 39-storey Secretariat building, part of the United Nations Headquarters in New York City, designed by Wallace Harrison with Le Corbusier and others. The UN, the largest and most representative international organization in the modern world, was founded in San Francisco in 1945 (Photo © DeA Picture Library).

*Plate 12*    A meeting of members of the North Atlantic Treaty Organization (NATO), Paris, December 1957. This international organization was founded on 4 April, 1949 to ensure a system of defence against the USSR and its allies (Photo © Bettmann/Corbis).

*Plate 13*    Patrice Lumumba, the first prime minister of the Democratic Republic of the Congo, following its independence from Belgium in June 1960. Sésé Sekoin Mobutu forced him from office soon after in a coup. He was assassinated in January 1961 (Photo © DeA Picture Library).

*Plate 14*    Anti-apartheid activist Nelson Mandela leaving prison in 1990, after nearly 28 years. In 1993, he and South African President F. W. de Klerk shared the Nobel Peace Prize for their efforts towards racial equality. Mandela was elected president of South Africa in 1994 (Photo © Kuus/Sipa-Press).

*Plate 15*    Egyptian President Anwar Sadat, US President Jimmy Carter and Israeli Prime Minister Menachem Begin on 17 September 1978 in Washington DC, at the signing of the Camp David Accords (Photo © Wally McNamee).

*Plate 16*    The first Palestinian *intifada* (Arabic for 'uprising') began in 1987 as violent civil protest against Israeli occupation of the Gaza Strip and the West Bank. Pictured here, a confrontation in Bethlehem in 1988 (Photo © Tiktiner/Sipa-Press).

*Plate 17*    On 9 November 1989, the Berlin Wall, a 49-km-long barrier constructed in 1961 to prevent residents of communist East Germany from defecting to free West Berlin, was opened to unrestricted transit. Soon after, this potent symbol of the Cold War was dismantled (Photo © Jacques Witt/Sipa-Press).

*Plate 18*    In 1993, Wayne Knox, of the Bell Laboratories, created a fiber-optic system capable of transmitting a laser beam (Photo © Roger Ressmeyer).

*Plate 19*    US astronaut Edwin 'Buzz' Aldrin Photographed on the Moon by Neil Armstrong on 21 July 1969, during the first human lunar landing, *Apollo 11* (Photo © Neil Armstrong).

*Plate 20*    Since the launch of *Sputnik I* in 1957, space has become an expanding venue for technological development. Orbiting satellites are the most ubiquitous symbol of this progress (Photo © DeA Picture Library).

*Plate 21*    One of the earliest British television sets from 1949. While the first long-distance public broadcast occurred in 1927, television only gained broad popularity during the 1950s (Photo © DeA Picture Library).

*Plate* 22 An Italian illustration depicting the assassination of Archduke Franz Ferdinand, heir to the Austro-Hungarian throne, in Sarajevo on 28 June 1914 by Serbian student Gavrilo Princip, which precipitated the crisis leading to the First World War (Photo © DeA Picture Library).

*Plate* 23 Indian nationalist leader Mohandas Karamchand Gandhi introduced a new style of political action based on non-violent civil disobedience, laying the groundwork for India's independence from Britain in 1947 (Photo © Bettmann/Corbis).

*Plate 24*  The Fascists' March on Rome, 28 October 1922. Spearheaded by Benito Mussolini (*centre*), founder of the Italian Fascist movement, this event led to his appointment as prime minister. Soon after, he declared himself dictator (Photo © DeA Picture Library).

*Plate 25*  Prisoners forced to labour in a Nazi concentration camp in Oranienburg, north of Berlin, during the Second World War. Hitler came to power in late January 1933 and established the first such camps only two months later (Photo © DeA Picture Library).

Plate 26   National Socialism, a German political movement based on nationalism, anti-communism, xenophobia and anti-Semitism, installed Adolf Hitler in 1933. Hitler's 'final solution' involved the systematic deportation and extermination of European Jews during the Second World War (Photo © DeA Picture Library).

Plate 27   Chinese soldiers of Chiang Kai-shek's Nationalist regime. He became leader of the unified Republic of China in 1928. During the Chinese Civil War (1926–49), he tried to eradicate communist opposition but failed, retreating to Taiwan (Photo © DeA Picture Library).

Plate 28   Japanese Emperor Hirohito ascended to the throne in 1926 and reigned until 1989. Here, he dons traditional attvire as part of his investiture as emperor (Photo © Bettmann/Corbis).

*Plate* 29　Adolf Hitler in Dortmund, Germany. In March 1936, the dictator reoccupied the demilitarized zone in Rhineland, near Dortmund, violating the Treaty of Versailles, which ended the First World War (Photo © Hulton-Deutsch Collection/Corbis).

*Plate* 30　Spanish general and dictator Francisco Franco during the Spanish Civil War (1936–39), which he won with the aid of Nazi Germany and Fascist Italy. In 1947, he declared Spain a monarchy and himself regent, maintaining power until his death in 1975 (Photo © DeA Picture Library).

*Plate* 31　German troops entering Warsaw, 1 September 1939. France and Great Britain declared war on Germany, two days after the Nazi invasion of Poland, officially beginning the Second World War (Photo © DeA Picture Library).

*Plate 32* Recently elected French President Charles de Gaulle visiting Algeria in 1958. De Gaulle came out of retirement to deal with the crisis surrounding the independence movement in the French colony, which continued until 1962 (Photo © DeA Picture Library).

*Plate 33* At the Yalta Conference, in the Crimea, in February 1945, Churchill, Roosevelt and Stalin defined the new European order in view of the imminent end of the the Second World War. Their decisions, including the division of Germany into four occupied zones, gave rise to the Cold War (Photo © DeA Picture Library).

*Plate 34*    Members of the East German *Freie Deutsche Jugend* (Free German Youth) demonstrating in 1950 in East Berlin against the US programme of European reconstruction, known as the Marshall Plan (Photo © Hulton Archive).

*Plate 35*    Soviet President Nikita Khrushchev and US President John F. Kennedy in Vienna in June 1961. Two months later, the Berlin Wall was erected, dividing the city until 1989 (Photo © DeA Picture Library).

*Plate 36*    Anti-Soviet demonstration in Prague, 1968. Under Alexander Dubček's leadership, political liberalization took hold in the Czech capital in the first months of 1968. Known as the Prague Spring, it came to an abrupt end when the USSR invaded (Photo © DeA Picture Library).

*Plate 37*　In 1985, Soviet leader Mikhail Gorbachev initiated a radical programme of economic and social reform, with *glasnost* (openness) and *perestroika* (restructuring) at its centre. He was awarded the Nobel Peace Prize in 1990 (Photo © A.P.N./Sipa-Press).

*Plate 38*　Samuel Nujoma during Namibia's independence ceremony in 1990. As Leader of the South West African People's Organisation (SWAPO), he led the battle against the occupying South African regime. In 1989, he was elected Namibia's first president (Photo © Laif/Sipa-Press).

*Plate 39*　Propaganda poster showing Mao Zedong, Shanghai, 1967. Architect of the People's Republic of China, he came to power in 1949 and launched the Cultural Revolution in 1966, during which revolutionary attitudes were encouraged, officials dismissed, and all aspects of culture destroyed (Photo © DeA Picture Library).

Plate 41    Jawaharlal Nehru became the first prime minister of India in 1947, following its independence from Great Britain (Photo © Baron).

Plate 40    Achmed Sukarno founded the Indonesian Nationalist Party in 1927 and led the country's struggle for independence from the Netherlands in 1949. He was deposed in 1965, during a bloody military coup (Photo © DeA Picture Library).

Plate 42    Yugoslav leader Josep Broz Tito, Indian Prime Minister Indira Gandhi and Egyptian President Gamal Abdel Nasser, in the late 1960s. India, Egypt and Yugoslavia formed part of the original Non-Aligned Movement, founded in 1961 to foster closer political, economic and cultural cooperation in developing countries (Photo © DeA Picture Library).

Plate 43 African-American minister Martin Luther King, during the 1963 march on Washington DC, where he delivered his 'I Have a Dream' oration. King championed civil rights through non-violent protest. In 1964, he received the Nobel Peace Prize. His assassination in 1968 provoked racial unrest across the US (Photo © Bettmann/Corbis).

Plate 44 Apartheid, meaning separation, was a system of racial segregation instituted by South Africa's white minority government in 1948. Signs like the one in this 1956 photograph were common until apartheid was formally abolished in 1990 (Photo © Hulton Archive).

*Plate 45* Child soldiers in Sudan, in 1971, during that country's civil war (1956–72). As many as 15,000 child soldiers may have participated in the conflict (Photo © Hulton Archive).

*Plate 46* Shantytown on the River Saigon in Ho Chi Minh City, Viet Nam. Population growth in developing countries has resulted in poverty-stricken urban neighbourhoods, such as this one (Photo © Owen Franken).

*Plate 47* Pakistani immigrant on arrival at London's Gatwick Airport. Immigrants from former British colonies have tended to relocate to Anglo-Saxon countries, where they have some knowledge of language and customs (Photo © Hulton Archive).

*Plate 48*  Festivities surrounding the meeting of the Organization of African Unity (OAU), Freetown, Sierre Leone, 1980. Founded in 1963, the OAU advocates solidarity among African nations, fosters decolonization and promotes economic development (Photo © Corbis).

*Plate 50*  The birth of Dolly the sheep in 1996, the first mammal cloned from an adult cell, heralded a scientific revolution as well as controversy regarding the potential for cloning of a human being (Photo © Najlah Feanny-Hicks).
*Plate 49*  Uneasy neighbours: luxury and squalor in a modern metropolis. Huge population increases have forced even advanced developing countries to grapple with extreme urban poverty in the face of economic prosperity (Photo © Paulo Fridman).

*Plate 51*    Female firefighters quelling a blaze after the Japanese attack at Pearl Harbor, 1941. Throughout the Second World War, US women were indispensable on the homefront and abroad (Photo © Hulton Archive).

*Plate 52*    Afghan Muslim women sporting a full *burqa*, 1997. Under the Taliban regime, a Sunni sect that ruled Afghanistan from 1996 to 2001, Muslim women were required to cover their entire bodies in public (Photo © Christine Spengler/Sipa-Press).

*Plate 53* Burmese opposition leader Aung San Suu Kyi was awarded the 1991 Nobel Peace Prize, while under house arrest (1989–95) for her efforts to bring democracy to Burma (now Myanmar). Here, she addresses supporters following her release in 1995 (Photo © Manuel Ceneta/AFP).

*Plate 54* English suffragettes during a demonstration in London, 1911. Women's suffrage, granted in the UK in 1928, was often the first step in an ongoing process towards full political, legal, socio-cultural and economic equality (Photo © Hulton-Deutsch Collection/ Corbis).

*Plate 55* Eritrean women waiting to cast ballots in a national referendum held in April 1993 on their country's independence from Ethiopia. The vote brought an end to a thirty-year civil war (Photo © Robert Papstein/ Sipa-Press).

*Plate 56* Golda Meir in 1948, preparing a speech during festivities marking the establishment of the State of Israel. She served as the country's fourth prime minister (1969–74) (Photo © Sipa-Press).

*Plate 57* The Beatles proudly display medals of the Order of the British Empire presented to them by Queen Elizabeth II in 1965. The renowned British rock group embodied the new youth culture (Photo © Bettmann/Corbis).

*Plate 58* Rue Gay Lussac, Paris, May 1968, in the aftermath of student protests. Such insurrections led to the recognition of modern youth as both a political and cultural force (Photo © Bettmann/Corbis).

*Plate 59*    Concertgoers at Woodstock '94, Bethel, New York, a rock concert commemorating the twenty-fifth anniversary of the legendary original gathering in 1969, which represented the culmination of youth and hippie counterculture (Photo © Henry Diltz).

*Plate 60*    Children on a street in Calcutta, India. Economic hardships in developing countries have fueled the exploitation of child labour, a subject of concern for human rights advocates (Photo © Nazima Kowall).

*Plate 61*    An elderly Chinese woman holding her grandson. In Chinese culture, senior citizens are greatly respected and venerated for their wisdom and experience (Photo © Paul A. Souders).

*Plate 62*    An older Korean woman dressing a girl in preparation for a shamanistic ritual. The elderly are vital to the transmission of social, cultural and religious customs to younger generations (Photo © Nevada Wier).

*Plate 90*  On 6 February 1995, the US shuttle *Discovery* attempted to dock with *Mir*, the Russian space station, heralding a new era of US-Russian cooperation in space exploration (Photo © ITAR TASS/Sipa-Press).

*Plate 91*  The 88-storey Petronas Twin Towers (1988) in Kuala Lumpur, Malaysia, were designed by Italian architect Cesar Pelli. Indigenous waste and recycled materials were utilized in their construction (Photo © John Dakers).

*Plate 92*  Centrale Solare Eurelios, an experimental solar power plant outside Adrano, Sicily. The continual rise in energy consumption has made the search for renewable forms increasingly important (Photo © DeA Picture Library).

*Plate 93*　A wind farm in Hurghada, Egypt. Like solar power, wind is an environmentally friendly, renewable energy source (Photo © DeA Picture Library).

*Plate 94*　A crude-oil loading bay in Kuwait, a member of the Organization of the Petroleum Exporting Countries (OPEC). The 11 nations comprising OPEC hold about two-thirds of the world's oil reserves. They supply 40 per cent of the world's oil production and half of the exports (Photo © DeA Picture Library).

*Plate 95*　Nuclear power station in Didcot, UK. In 1956, the world's first large-scale commercial reactor generating electrical power began operating in Calder Hall, UK (Photo © DeA Picture Library).

*Plate 96*   Polish-born British anthropologist Bronislaw Malinowski achieved recognition for his theory of reciprocity, based on pioneering ethnographic fieldwork in Papua New Guinea (Photo © Hulton-Deutsch Collection/Corbis).

*Plate 97*   French sociologist and anthropologist Pierre Bourdieu, whose work addressed social patterns of power as well as individual and group behaviour, inventing concepts such as social and cultural capital (Photo © Alain Nogues).

*Plate 98*   French pioneer of modern sociology Emile Durkheim. He advocated that the methods of natural science be applied to the study of society (Photo © Bettmann/Corbis).

*Plate 99*   With Durkheim, the German Max Weber founded the field of modern sociology. His pioneering work on religion argued that it explained, in part, differences in the development of Eastern and Western cultures (Photo © Bettmann/Corbis).

*Plate 100*    British economist John Maynard Keynes (centre) during a UN conference. His work, the basis for macroeconomics, advocated governmental intervention to spark employment and economic prosperity (Photo © Hulton Archive).

*Plate 101*    German defendants at the Nuremberg Trials, legal proceedings against Nazis accused of war crimes following the Second World War. Judges from the USA, UK, France and Soviet Union presided over the military tribunals held in Nuremberg, Germany, from 1945 to 1948 (Photo © Corbis).
*Plate 102*    US linguist Noam Chomsky, creator of the Chomsky hierarchy, a classification system of formal languages introduced in the 1950s that revolutionized contemporary linguistics (Photo © Christopher Felver).
*Plate 103*    British philosopher and political activist Bertrand Russell. His contributions to philosophy were in the areas of mathematics and logic. An ardent liberal, he promoted nuclear disarmament and criticized the Vietnam War (Photo © Bettmann/Corbis).

*Plate 104*    French philosopher and writer Jean-Paul Sartre was one of the principal exponents of existentialism, a philosophical movement emphasizing the individual and individual experience (Photo © Genevieve Naylor).

*Plate 105*  French anthropologist Claude Lévi-Strauss employed structuralism, the exploration of the inter-relationships through which meaning is produced, as a means of understanding human culture and society (Photo © Sophie Bassouls).

*Plate 106*  Indian poet and philosopher Rabindranath Tagore was awarded the 1913 Nobel Prize in Literature, making him the first Asian to receive the honour (Photo © E. O. Hoppe).

*Plate 107*    Mausoleum of Chinese leader Sun Yat-sen, Nanjing, China. His political philosophy, outlined in 1905 and known as Three Principles of the People, included the concepts of nationalism, democracy and prosperity (Photo © Keren Su).

*Plate 108*    Japanese philosopher Nishida Kitaro dubbed this locale, which he passed through regularly, the Pathway of the Philosophers. Kitaro assimilated European philosophical tenets with historical Japanese experience, expounding on concepts like 'place' (Photo © Macduff Everton).

*Plate 109*    Julius Nyerere, the first president of the United Republic of Tanzania (1964–85), adhered to a nationalist-ideological philosophy, claiming that ideological freedom and a return to traditional African humanism accompanied genuine independence (Photo © Liz Gilbert).

*Plate 110*    Mexican writer, philosopher and politician
José Vasconcelos, 1929. Supporter of the 1910
revolution, he created and ran the Ministry of Public
Education (1920–25) (Photo © Bettmann/Corbis).

*Plate 111*    The Greenpeace vessel *Rainbow Warrior*, sunk by the French secret service in 1985. Greenpeace,
an international environmental organization founded in 1971, has staged dramatic protests to draw attention to
ecological issues ranging from nuclear testing to whaling (Photo © Adrian Carroll).

*Plate 112*  A Muslim woman wearing a chador in Tehran, Iran, required dress under fundamentalist Islamic law. She walks past a poster of the Ayatollah Khomeini, spiritual and political leader of the 1979 Islamic revolution and advocate of fundamentalism (Photo © David Turnley).

*Plate 113*  Korean followers of neo-Confucianism during a ceremony commemorating the birth of Confucius. A return to traditional beliefs, rather than the adoption of Western values, has accompanied modernization in some Asian cultures (Photo © Nathan Benn).

*Plate 114*  A young Shinto nun. Shinto ('way of the Gods') is the natural religion of Japan. Many Japanese have adapted its ancient, polytheist practices and principles to modern urban life (Photo © Chris Rainier).

Plate 115  Nuns in San Salvador,
El Salvador, where Archbishop Oscar
Romero was assassinated in 1980.
Romero's advocacy for the poor and
victims of his country's civil war made
him a target for right-wing
paramilitary death squads
(Photo © Bettmann/Corbis).

Plate 116  Buddhist monk in Burma (now Myanmar),
where the ancient religion became associated with
nationalist movements (Photo © Jeremy Horner).

Plate 117  Young novices at the Gandan
monastery, Ulan Bator, Mongolia. During its close
association with the USSR, during much of the
twentieth century, the Mongolian Government
tried to eradicate local Buddhist practices
(Photo © Michel Setboun).

Plate 118    Indian holy men praying on the River Ganges. Thousands of Hindu pilgrims purify themselves in its waters during Kumbh Mela, an important religious festival celebrated every 12 years (Photo © Ludwig/ Sipa-Press).

Plate 119    A Jewish school in the ultra-orthodox Mea Shearim quarter in Jerusalem. The Arab-Israeli conflict has witnessed a rise in conservative religious practices among certain Israeli Jews. (Photo © Bojan Brecelj).

Plate 120    Muslims at the Dome of the Rock in Jerusalem at Ramadan, the ninth month of the Islamic year, during which Muslims fast. Islam has proven a fundamental factor in many social movements in certain Muslim countries (Photo © Richard T. Nowitz).

*Plate 121*    Pope John Paul II blessing a crowd in Zaire (now the Democratic Republic of the Congo), 1980. While supporting human rights and social justice, he remained fundamentally conservative on issues like women in the Church, contraception and sexual mores (Photo © Vittoriano Rastelli).

*Plate 122*    Commemoration of the fiftieth anniversary of the US atomic bomb attack of 6 August 1945 at the Hiroshima Peace Memorial (Photo © Qualyle-Orion/Sipa-Press).

Plate 123  Sperm samples used in *in vitro* fertilization. This controversial technique, in which egg cells are fertilized outside a woman's body, was developed in the UK, where the first so-called 'test-tube baby' was born in 1978 (Photo © Reserved Rights).

Plate 124  Genetically engineered maize cultivated in a laboratory in Palo Alto, California. Despite its role in fighting world hunger, genetic engineering of plants and animals continues to ignite debate, mainly due to possible secondary effects on humans (Photo © Lowell Georgia).

Plate 125  Convoy of the International Red Cross arriving in Kigali, Rwanda, 1993, with humanitarian aid for refugees who were victims of the ethnic wars in the region (Photo © Patrick Robert).

*Plate 126* Russian physiologist Ivan Pavlov received the 1904 Nobel Prize in Medicine or Physiology. He is best remembered for his experiments with dogs, which proved that an automatic conditioned reflex can be artificially induced (Photo © Bettmann/Corbis).

*Plate 127* Young Inuit woman, carrying her child on her back, 1903. Anthropological fieldwork conducted in the early twentieth century helped undermine popular, evolutionary paradigms employed to classify so-called 'primitive' cultures and indigenous peoples (Photo © Michael Maslan).

*Plate 128* The automobile assembly line, introduced by US industrialist Henry Ford in 1913, revolutionized labour techniques and initiated mass production (Photo © Bettmann/Corbis).

*Plate 129*    Performance of Japanese kabuki, a theatrical form first developed in the seventeenth century. In this popular genre, incorporating highly stylized mime, song and dance, men perform all the roles (Photo © Michael S. Yamashita).

*Plate 130*    A typesetter working on a linotype machine, 1970. First produced in 1886, the linotype machine, with its ninety-character keyboard, transformed the printing industry (Photo © Bettmann/Corbis).

*Plate 131*    US composer George Gershwin mixed elements of Jewish popular music with jazz and classical music. He and his brother, Ira, wrote several Broadway musical hits (Photo © Bettmann/Corbis).

Plate 132    Poets André Breton, Paul Eluard, Tristan Tzara and Benjamin Péret, 1932. During the First World War, Tzara founded dada, an aesthetic movement advocating anarchy and absurdity. From dada, emerged surrealism, a movement embracing the powers of the unconscious, of which Breton, Eluard and Péret were leading practitioners (Photo © Stefano Bianchetti).

Plate 133    Russian author Ivan Bunin (*seated, right*). In 1919, in the aftermath of the Russian Revolution, he immigrated to France. He became the first Russian to win the Nobel Prize in Literature (1933) (Photo © Michael Nicholson).

Plate 134    Irish-born writer Samuel Beckett settled in Paris in 1938, where he spent most of his adult life. In 1969, he received the Nobel Prize in Literature (Photo © Hulton Archive).

Plate 135    French writer Marguerite Yourcenar was celebrated for her historical novels, such as *Memoirs of Hadrian* (1951). In 1980, she was the first woman elected to the Académie Française (Photo © JP Laffont).

Plate 136    Indian-born UK author Salman Rushdie (*left*), South African writer Nadine Gordimer (*centre*) and German novelist Günter Grass (*right*), three icons of twentieth-century literature (Photo © Telepress/ Corbis Sygma).

Plate 137    US writer F. Scott Fitzgerald with his wife Zelda, and daughter. His work, most notably *The Great Gatsby* (1925), exposed the social and moral corruption during the 'jazz age' of the 1920s (Photo © Bettmann/Corbis).

Plate 138    US writer Arthur Miller and his wife, actress Marilyn Monroe, 1956. Miller's plays, including *Death of a Salesman* (1949) and *The Crucible* (1953), addressed morality and the societal and family pressures individuals endure (Photo © Corbis).

*Plate 139*    African-American author Richard Wright. In *Black Boy* (1945) and other novels, he examined the horrors of racial segregation and its effects on African Americans (Photo © Bettmann/Corbis).

*Plate 140*    Caribbean poet and playwright Derek Walcott was born in St Lucia. He received the 1992 Nobel Prize in Literature for his subtle portrayals of the history, geography and everyday life of the multiracial peoples living in the Caribbean (Photo © Brooks Kraft).

*Plate 141*    Argentine writer Jorge Luis Borges, one of the foremost contemporary Latin-American authors. In his poetry and short stories, he explored themes of time, reality and identity (Photo © Sophie Bassouls).
*Plate 142* Colombian writer Gabriel García Márquez with a copy of his most famous novel, *One Hundred Years of Solitude* (1967), on his head. He won the Nobel Prize in Literature in 1982 (Photo © Colita/Corbis).

*Plate 143* Nigerian writer Wole Soyinka (*left*) with a group of journalists. In 1986, he became the first African to be awarded the Nobel Prize in Literature (Photo © Jacques Langevin).

*Plate 144* Indian writer and anthropologist Amitav Ghosh. Considered one of the finest Indian authors working in the English language today, he published his first novel, *The Circle of Reason*, in 1986 (Photo © Sophie Bassouls).
Plate 145    Japanese novelist Yasunari Kawabata. In 1968, he became the first Japanese writer to win the Nobel Prize in Literature, for novels such as *Snow Country* (1947) and *The Master of Go* (1956) (Photo © Bettmann/Corbis).

Plate 146    Bust of Lu Xun, considered the father of modern Chinese literature. His first major work, *A Madman's Diary*, inspired by Gogol's tale, was published in 1918 (Photo © John T. Young).

Plate 147    Pablo Picasso, *Les Demoiselles d'Avignon*, 1907, oil on canvas. A representation of female prostitutes, the faces of whom derive from African and Iberian sculpture, the painting heralded cubism and remains an icon of modernism (Photo Museum of Modern Art, New York. Lillie P. Bliss Bequest © 2004 Estate of Pablo Picasso/Artist Rights Society [ARS] New York).

Plate 148    Pablo Picasso, *Guitar* 1912, cardboard and string. This relief sculpture marked the transition from analytical to synthetic cubism. In his representation of space and volume using simple materials, Picasso revealed his ongoing dialogue with African sculpture (Photo Museum of Modern Art, New York, gift of the artist © 2004 Estate of Pablo Picasso/Artist Rights Society [ARS], New York).

Plate 149    Vladimir Tatlin, *The Sailor*, 1911–12, oil on canvas. In composition and technique, this early self-portrait suggests, in part, the influence of orthodox icons in the artist's native Ukraine (Image courtesy SCALA/Art Resource, New York © Estate of Vladimir Tatlin/Licensed by VAGA, New York).

Plate 150    Vladimir Tatlin, model for *Monument to the Third International*, 1920, wood, cardboard, metal, wire, oil paper. Tatlin achieved fame for this visionary work of modernist architecture. In iron, glass and steel, it would have dwarfed the Eiffel Tower, had it been constructed (Photo © Estate of Vladimir Tatlin/Licensed by VAGA, New York).

*Plate 151*   Carlo Carrà, *Interventionist Demonstration*, 1914, tempera and collage on cardboard. Carrà was a leading figure in futurism, the Italian avant-garde movement that championed speed, technology and violence (Photo © 2004 Artist Rights Society [ARS], New York/SIAE, Rome).

*Plate 152*   Max Ernst, *Celebes* (*The Elephant Celebes*), 1921, oil on canvas. Named for the Indonesian island, which the artist had never visited, the painting presents an imaginary dream world (Photo © 2004 Artist Rights Society [ARS], New York/ADAGP, Paris).

*Plate 153*  View of the Exposition Internationale, Paris, 1937. Standing opposite one another are the German pavilion (*right*), designed by Hitler's architect Albert Speer, and the Soviet pavilion (*left*), on the roof of which stands a massive sculpture of a man and woman triumphantly joining hammer and sickle (Photo © courtesy the Getty Research Institute, Resource Collection: Exposition Postcard Collection Archive).

*Plate 154*  Pablo Picasso, *Guernica*, 1937, oil on canvas. The artist took as his subject the bombing of the Basque village of Guernica by the Nazis aiding Franco's regime. First exhibited at the 1937 Exposition Internationale, the mural remains a potent anti-fascist and anti-war symbol (Photo © 2004 Estate of Pablo Picasso/Artist Rights Society [ARS], New York).

Plate 155 Kazuo Shiraga, *Untitled*, 1957, oil, watercolour, ink on paper mounted on canvas. The Japanese artist belonged to the Gutai ('Concrete') art association, which was devoted to ephemeral actions. Shiraga painted this monumental work, using various parts of his body, during one such performance (Photo © CNAC/MNAM/Réunion des Musées Nationaux/courtesy Art Resource, New York).

Plate 156 Jackson Pollock, *Number 1, 1948*, 1948, oil on canvas. In this archetypal, abstract painting, fashioned through drips and skeins of paint, the artist asserted his presence by including his handprints in the upper right corner (Photo © 2004 The Pollock-Krasner Foundation/Artist Rights Society [ARS], New York).

Plate 157 Robert Rauschenberg, *Coca-Cola Plan*, 1958, mixed media. Incorporating found objects, this sculpture speaks to the increasing importance of and interrelationship between popular and consumer culture in the USA (Photo © Robert Rauschenberg/Licensed by VAGA, New York).

Plate 158 Robert Smithson, No. 7 from *Yucatan Mirror Displacement*, 1–9, 1969, nine chromogenic development slides. In such site-specific works, known as land art, Smithson examined the relationship between an artwork and its environment (Photo © Estate of Robert Smithson/Licensed by VAGA, New York).

*Plate 159* Pierre de Coubertin, founder of the modern Olympic Games. Athens hosted the first Olympics in 1896, Greece being the original location of the games during Antiquity (Photo © CIO, Musée Olympique, Lausanne).

*Plate 160* Poster designed by French artist Auguste Matisse for the first Olympic Winter Games, held in Chamonix, France, in 1924 (Photo © CIO, Musée Olympique, Lausanne).
